COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College

Gentlemen,—We now come to the consideration of cerebral and nervous diseases, which are a very important class. They comprise pleuritis, meningitis, apoplexy, paralysis, paraplegia, and hemiplegia; arachnitis, hydrocephalus, cerebritis, and various other affections connected with them. When we consider the close connexion which subsists between the different parts of the body, and the functions exercised by the nerves, it is no wonder that several parts are simultaneously affected. Thus, we may have diseases affecting the sensorial and motor functions, both voluntary and involuntary, either separately or simultaneously. But, what are the pathological causes which interfere with the functions of the nervous system? They may be classed under several heads. First, mechanical causes—of two kinds—affecting the function of the brain, and the nervous system generally. A mechanical cause, such as the impaction of a spicula of bone, or a needle, in any part of the nervous system, has the effect of irritating and producing increased nervous action, indirectly or directly; the motor function may be affected, and motion will be the result; or the sentient function, with pain as the result. Pressure upon a nerve may produce irritation, and, by destruction, cause a cessation of the nervous function.

Paralysis leads to the suspension of the functions of the nervous system, and to a loss of consciousness, and stupor. Another class of mechanical causes, which operate in another way, are those arising from pressure, which are productive of great distress. By pressure, I mean a stoppage of the circulation. The third class of causes are those by which the functions of the brain are affected, through the medium of the circulation. These are susceptible of two divisions: first, those which cause an increase of the circulation through the brain, or the nervous system generally, causing excitement of the functions of the nervous system. This effect is allied to some kinds of determination of blood to the head. On the contrary, a diminution of the circulation causes the opposite state, a diminution of the functions of the various parts of the nervous organism. This may arise from extreme pressure on any part of the skull, such as may be caused by fracture, with depression of the bony covering of the brain. The effect of such injury is to cause a diminution of the cerebral circulation, and a consequent impairment or total suspension of the functions of the brain. The same cause may lead to a suspension of the functions of the spinal marrow. Effusion of serum within the cerebral membranes will also cause pressure on the brain; which, however, chiefly affects the blood-vessels of the part. Hæmorrhage within the skull has a similar effect. Now, the excitement arising from increased, and the oppression caused by diminished circulation, may affect the whole system, or certain parts only; sometimes, there arise a remarkable combination of symptoms produced by both these causes; take the case of sanguineous or serous effusion of the brain, or any other cause that may interrupt the sensorial power. What is the result? Consciousness is suspended; and it sometimes happens that the spinal functional power is increased extraordinarily by some other means, not at all connected with the sensorial function. But, the excito-motory system is exalted by some means, and how? Why, in various ways. If the blood cannot get to the upper part of the brain, pressure will be exercised by the impetus necessarily communicated by this cause to the circulating fluid in that portion of brain through which it passes, that pressure on the upper part of the skull stops the circulation, and, at the same time, produces a counter-pressure on the various parts at the base of the skull; the effect of which, is mechanical congestion, causing convulsions. During a general suspension of consciousness, you may have convulsive action, or increased functional power of the excito-motory system. If pressure is exercised on the upper and lower portions of the brain, the effect will be not only to suspend the circulation in, but to help to squeeze the parts which pass through, the foramina further out of the skull. A good deal of nonsensical discussion has lately taken place about the compressibility or non-compressibility of the brain. It is not compressible, though it may be said to be squeezable; it may be displaced by pressure from one part to another. The third class of causes, interrupting the function of the brain, and the spinal marrow, are those which exhaust their power, such as undue excitement, however produced; and you always find after undue, or long-continued, excitement, an unnatural increase of power. Some parts of the brain require more rest than others, and, generally speaking, the portions of brain that require the most rest are those most liable to be exhausted by excitement. Such parts are those that are connected with the sensorial, and animal functions; on the other hand, those that require least rest, are the seat of the involuntary and excito-motory functions. The fourth class of influences which injure or disturb the nervous system, are poisons and drugs, some of which are exciting, and some depressing, while others, as opium, produce both effects. We have next to speak of inflammation of the brain and its membranes. This inflammation, and its symptoms, will vary, according to the part affected, the extent of structure implicated, and the predominance of the peculiar elements of the inflammation, whether congestive, or determinative, and the products, the result of inflammatory action. Meningitis is an inflammation of the pia mater, and arachnitis of the arachnoid membrane. The term "meningitis," however, is loosely and generally applied to inflammation of any of the membranes of the brain. In the most perfect forms of this disease, the following are the symptoms observed: There may be some excitement from the beginning, wakefulness, and an exaggerated sensibility to light and sound; the eyes cannot bear so much light as usual; there is more or less pain in the head; and an increase of the sensorial function; there is an increased flow of ideas, and these become more and more rapid; thoughts obtrude themselves on one another in such a hurry, that at length they become confused, and the mind cannot exert controul over them. In this manner occurs the transition of the function of thought from health to disease—from reflection and consciousness to delirium. This is called phrenitic delirium or phrenzy. As this goes on, there are the common symptoms of inflammation: headache, flushed face, red and ferrety eyes, the carotids beating, and a hard, strong pulse; with these there is more or less of inflammatory fever. These symptoms may continue in a greater or less degree, until they are followed by those which arise from the effects of inflammation. If the effect is very great excitement of the cerebral functions without any considerable effusion, the patient may die in a state of syncope; but more generally the symptoms, if not subdued, pass into those of depression, stupor, paralysis, strabismus, and coma. Symptoms like these are to be referred to an increased rapidity of the circulation. In another case with symptoms of insanity and excitement, there will be more or less lethargy, sluggishness, stupor, and heaviness: the pupils, instead of being contracted are dilated, and there is general dulness of the senses, with some headache, and sickness, from the sympathetic effect on the stomach and its nerves. Frequently with this there is an irregular or unequal pulse, with it may be, partial paralysis of the limbs, and sometimes suppression or retention of urine. These symptoms may pass at once into coma, and total suspension of the functions of the brain; there will be laboured pulsation of the carotids, hard full pulse, and heat of head, which symptoms, however, are chiefly those of congestion, not inflammation. In many cases, congestion is the first stage of inflammation, but very frequently it does not go on and pass into coma without the more marked symptoms of excitement, and it often happens after the symptoms of heaviness and lethargy have continued for some hours or days, that there shall suddenly arise in the midst of that excitement more or less of delirium, accompanied by contracted pupils, high fever, hard strong pulse, convulsions, exhaustion, or coma, and other symptoms of acute hydrocephalus. The appearances after death will be much the same in both cases; increased membranous vascularity; effusion of serum under the arachnoid, or slight purulent effusion beneath all the membranes, and also into the cortical structure of the brain. The cortical structure is sometimes discoloured, being redder, or of a slight brownish tint, and in some parts softened; this state of softening is easily perceived where the structure in question is scraped by the scalpel.

There are some more obscure cases even than those which have been mentioned, in which there are symptoms of arachnitis, great headache, heaviness, and great giddiness. A case is mentioned by Cruvelhier, of a patient who was supposed to be pretending to be idle; the pulse appeared quite natural, and in appearance there was nothing wrong about him; he was ordered to get up and would not do so; he was very easily frightened, and he died soon after, in a state of coma. On examination, there was found an effusion of serum under the arachnoid.

There is another class of cases of a still more chronic kind, where the mischief chiefly attacks the dura mater, causing obstinate headaches, accompanied by a full and bounding pulse, whose action is increased when the patient lies down. These cases may arise from external causes, such as shocks given to the head, or from rheumatic affections of the dura mater. In such cases there is external soreness widely extending over the head. It is most probable that these affections are not really inflammatory, but rather congestive affections, for if they are inflammatory, the inflammation must be confined to the dura mater, and must necessarily involve other membranes, or the substance of the brain itself.

Inflammation attacking various portions of the brain will necessarily produce varying symptoms. It is said to cause pain and delirium, stupor, paralysis, and convulsions, or infiltration when it attacks the base of the brain. This is far from being constantly the case. The pressure and counter-pressure are here to be considered. The effusion which arises is accompanied by stupor, and in some cases by convulsions, in the way I have described, by the pressure of the external parts dividing the force of the circulation to the lower—or the counter-pressure to the upper parts. Chronic meningitis* is of an inflammatory character, accompanied by headache, heaviness, general torpor, considerable irritability of the mind, confusion of ideas, loss of memory, and convulsive motions, and terminates in paralysis or dementia, or else it may prove fatal by coma. Inflammation of the substance of the brain, or cerebritis, varies greatly in its symptoms from meningitis, or arachnitis. It differs from meningitis not only in the amount and nature of the product of the inflammation, but it alters the symptoms of meningitis when co-existing with the latter. In some cases it is rapidly fatal, and these, like meningitis, in its highest degree, are accompanied by the various symptoms I have mentioned as characteristic of the latter disease. When the pia-mater is inflamed, and the substance of the brain is extensively affected, the pulse is weak from the commencement, but it is often hard when the membranes alone are affected. In inflammation of the pia-mater, the pain is less and of shorter duration; the tendency to end either in paralysis, or partial or complete coma or convulsions, or both together, is greater than in inflammation of the dura-mater. Partial cerebritis may vary in the first symptoms, according as it is preceded by congestion or irritation. If it be preceded by congestion, there may be a dull pain in some part of the head, chiefly felt in stooping, with giddiness, not relieved by lying down, and there may also exist loss of memory of words, with nervousness, and a deficiency of energy and quickness of mind, a disposition to be excited by trifling causes, a trembling and tottering gait, afterwards followed by a state of spasmodic rigidity; phantasms, specks before the eyes, and spectral illusions. These symptoms may terminate in weakness of the organs and paralysis of the various parts connected with the portion of brain affected. In the more advanced form there is a more complete perversion of the cerebral functions, and there will be excitement or depression, according as vascular action or effusion and disorganisation prevail. Disorganisation will have an opposite effect to irritation—that of suspending the cerebral function.

This partial cerebritis, which is by far the commonest, may terminate in the chronic form, and this may be accompanied by greater or lesser continuance of its symptoms, or followed by effusion of serum or blood into the substance or upon the surface of the brain; the result of which will be palsy, more or less complete, apoplexy, and a general interference with the functions of the brain. On examination after death, in such cases, *ramollissement* is often discovered. This is of two kinds, red and yellow softening; red softening is characterised by sanguineous congestion; this occurs in the earliest stage of the inflammation. Yellow softening arises from an infiltration of purulent matter into the substance of the brain, which is broken up; in some cases a portion of the brain is absorbed, and an abscess formed. *Ramollissement* exhibits other shades of colour, such as brown or green. In some cases the softening goes on to sphacelus or gangrene. There is still much doubt as to the exact relation of the seat of the lesion to the disease, and it seems to be the opinion of some writers that those diseases affecting the medullary portion of the brain are accompanied by paralysis; and those affecting the cortical part are followed by delirium, a disease of the sensorium ending in coma. It certainly is very remarkable, that where you have softening, involving the roots of the nerves, it does interrupt their function in a distinct manner; and it is a common result with regard to the two hemispheres, that disease of one affects sensation and motion on the opposite side of the body.

The causes of encephalitis, phrenitis, and meningitis, may be mechanical injuries to the head, excessive mental excitement,—both circumstances producing determination of blood to the head—anxiety, excessive indulgence in intoxicating liquors, or exposure to the sun's rays, causing what is called in hot countries the blood stroke, will produce the same results. Another species of inflammation is ostitis,* which derives any claim to danger it may possess from its tending to run into cerebritis. There is also erysipelatous inflammation of the scalp, an affection highly dangerous; and syphilitic cranial periostitis is a disease to be dreaded, as occasionally productive of injury to the cerebral functions. Inflammations of the brain often arise as complications of fever, or they may supervene from the various causes of cerebral congestion. Asphyxia, irritation of the intestinal canal, and a peculiar excitability of the nervous plexus, which exists in many individuals, are often exciting causes of this inflammation in its violent form.

ON BRIGHT'S DISEASE OF THE KIDNEYS.

By D. J. Corrigan, M.D., Physician to the Whitworth, Hardwicke, and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

This is the disease which has been described by Blackhall under the name of inflammatory dropsy. It is found to occur sometimes after scarlatina, as well as after exposure to cold. In such cases anasarca sets in suddenly, the pulse is high, the skin is hot, the urine high coloured, of a high specific gravity 1.020, and contains albumen, the tongue is white, and there is vomiting and pain across the loins. What it is that produces the anasarca here we do not know; we know that such a thing is there, but that is the whole amount of our knowledge. Of the nephritis itself the anasarca can be neither cause nor effect; it is merely an accompaniment of the disease, just in the same way as we find œdema of the side in pericarditic or pleuritic effusion, in which no vascular connection can be traced between the serous membranes affected and the œdematous parts. We also observe this latter symptom in renal or lumbar abscess, where there is a thickness of parts to the extent of some inches between the seat of the collection of matter and that of the œdema. Neither can it proceed from vascular congestion, for *post-mortem* investigations do not discover the least trace of congestion in the parts. As I have said already, we know it is there, but *how* it came there we cannot tell. In treating this form of dropsy you would err greatly were you to confine your remedial measures solely to the removal of the dropsy, without directing your attention to the state of the kidneys.

Bleeding from the arm in a full stream, as directed by Blackhall, the application of leeches, or cupping glasses to the loins, followed by vesication, aided by the internal exhibition of antim. tart. or James's powder in suitable doses, may be prescribed at first. As soon as the pulse is lowered, and the skin has become cool, you may direct the administration of mercury to excite salivation to a very moderate extent. Under this treatment the anasarca will be removed, and the disease disappear for the present, and not a few cases are thus permanently cured. The attack for the present is removed; in some time after your patient comes to you, again seeking relief, having, as he says, caught a relapse from cold. This is removed again and again, until the disease has attained to that pitch of intensity which constitutes the immediate subject of this evening's lecture. Up to this time neither the ascites nor the anasarca will have become considerable, and the collection of water in the abdomen—depending neither on heart disease, such as contraction of the auriculo-ventricular opening, nor on actual disease of the peritoneum, but on some peculiar cause at present inexplicable to us—does not reach beyond a somewhat definite amount. The disease has now acquired an intensity which previously it did not possess. What is that produces this mischief? Of the disease under examination called "Bright's Disease of the Kidney," from having been first elucidated by that gentleman, there would appear to be two varieties. In one of these the kidney becomes larger than natural, of a mottled yellow colour, which gradually spreads over the whole gland, and the tubuli uriniferi extend far towards the cortical part of the kidney. In the other variety the kidney becomes smaller than in health, the tubuli uriniferi traverse a much greater space through the kidney than in the former, running in this variety almost to the capsular covering; its surface becomes studded with minute tuberosities, which project above the capsule, as if numerous grains of small shot were irregularly distributed through, and sunken into, the cortical portion of the kidney. I regret very much that I forgot to bring with me a specimen of kidney affected with this variety of disease, which was taken from a young boy who died of it. The *post-mortem* was made this morning. This preparation (handing one round), although it has lost its peculiar colour, will, however, serve to give you some idea of the diminution in size which the organ undergoes, and it preserves pretty well the appearance of these granular bodies of which I have already spoken as projecting above the capsule of the kidney. In that variety where the kidney has become enlarged, the urine continues of nearly the natural specific gravity, ranging from 1·015 to 1·025 and is still secreted abundantly as in health, nay, sometimes more so, for we often find the patient obliged to get out of bed four or five times of a night to make water, while the quantity he passes far exceeds that of the natural secretion; even under this profuse diuresis, we find the accompanying anasarca not at all lessened, plainly proving that both are independent of each other. Albumen is still secreted in the urine, and the colouring matter of the blood is often deposited in that excretion. In other words, blood is passed with the water. In the other variety the urine becomes of a specific gravity, far below the natural standard,—1·005 to 1·010,—it loses its peculiar colour, and, in proportion as the disease advances in malignancy albumen diminishes, until in its highest stage it disappears altogether, and the "tubuli uriniferi" allow nothing to pass through them but water almost quite pure. The circumstance of albumen being wanting altogether in the worst forms of the disease, has led persons to criticize the remarks of Bright, and to speak of them as being destitute of accuracy; but, had they examined his writings carefully, they would have found that Bright himself states that fact. We have next to enquire how it is that this disease proves fatal. We find from the experiments of Christison, that in persons labouring under this variety of disease, the urine is deprived altogether, or almost, of its salts, and loses it peculiar principle, urea. That from the loss of its salts, this fluid has become of a less sp. gr. than natural, as indicated by the hydrometer, but the same ingenious observer has extended his remarks further, and has found, that the blood, when submitted to proper chemical manipulation, has yielded urea in quantity. Being aware of these facts, it is not unnatural for us to suppose, that the mass of circulating fluid becomes poisoned by the retention in it of these peculiar saline particles, which it is the

---

* By the indefinite term "Ostitis," Professor Williams means to express a definite osseous inflammation, that of some portion of the cranium.

proper office of the kidney to eliminate. The fatal event is brought on by effusion into the cavity of the pleura, or by a combination of gastric with head symptoms; these latter set in at first with vomiting, and are quickly succeeded by fatal coma or convulsions. Of the termination by effusion into the pleura we have at present an instance at the Hardwicke in Mrs. Scully. About eighteen months since she was first attacked with the primary nephritis: she had been frequently relieved before this last attack, but now effusion within the chest has set in, and she is hurrying rapidly along "the way of all flesh." With regard to the following observations which I am about to make on this subject (having thus sketched at length for you the disease as it exists), I beg to apprize you that I do not put them forward as possessing any claim to credit further than what their own correctness shall entitle them to. I place them before you as the result of conviction, forced upon me by years of careful observation of this disease; and, believe me, that to make an observation correctly, which will enable us to bring our knowledge of the pathology of an organ to bear properly on its means of cure, is often the work of years. The observations I have to make consist in the assertion and proof that both these varieties of "Bright's disease" are identical in origin and progress with the two diseases which I have spoken of some evenings since, under the names of hypertrephy and cirrhosis of the liver. My reasons for this opinion are drawn from the similarity of appearance which the kidney, in both varieties of Bright's disease, presents to the liver affected with the before mentioned diseases. They are drawn, also, from the relative effects which both these renal affections produce on the duration of life, corresponding exactly to those produced by the liver in either states of hypertrephy and contraction. When a section of the kidney, affected with the first variety of renal disease of which I have spoken is made, you perceive the same yellow colour running all through its cortical tissue, just in the same manner as it pervades the liver when in a state of hypertrephy. Here you have plates (exhibiting them) which, taken from Nature, clearly demonstrate the identity of mottled appearance, which pervades both kidney and liver in their first stage of hypertrephy. The enlargement in both organs arises from an extraordinary effusion of lymph within the body of each gland, and which lymph, becoming organized, increases both to their present size. In the contracted and less-ened variety, which I shall venture to call cirrhosis of the kidney, we find the same effects caused as had previously taken place in the liver. In both organs this arises from the contractility of the effused lymph. In this last variety of "Bright's disease," the substance of the gland, or, as it is termed, the "acini," does not become the seat of effusion. This is confined solely to the cellular tissue, the matrix of the gland; and the lymph effused here, afterward, on its contraction, exerts such pressure upon the acini as to produce these irregular elevations which we find studding the surface of the kidney in this affection. This contraction also exerts such pressure upon the secreting vessels of the organ, as to prevent the passage through them of any fluid denser than water. After death has taken place, on dissection we find the tubuli uriniferi extending to within a very short distance of the capsule, and but a very little of the cortical structure remaining.

It remains for us to see, if this view which I have taken of the disease can be of any use in rendering our treatment of it more successful, or if there are any signs recognisable during life, which point out to us which state of disease our patient is labouring under. With regard to the successful event of the treatment, others must decide, but I am confident that there are signs which, during life, plainly tell us under what variety of "Bright's" disease it is that our patients labour. I have found the the following symptoms invariably pathognomonic of each variety. In these cases, where the kidney has arrived at the state analogous to that of the large hypertrephied liver, we find the urine secreted abundantly, as in health, or even more so, sometimes tinged with blood, albuminous, of a specific gravity, not much below the natural standard, averaging from 1·015 to 1·025; along with these the skin is dry and hot, and there is pain across the loins: while in cases where, in addition to the two latter symptoms, you have the urine decreased in quantity, though albuminous, and of a very low specific gravity—1·005 to 1·010—*there* you may confidently say, that cirrhosis has fairly set in. It is easy to understand why one should be a disease of comparative obedience to medical treatment, and why its fellow should be so productive of effects, certainly fatal. We can naturally suppose, that in a case where the urine continues to be secreted natural in quantity, and containing nearly the average ratio of its saline ingredients, nothing can be going forward (as far as the kidneys are concerned) which can be productive of much constitutional injury. It may be said, that the presence of albumen in the urine would, in the foregoing case, bring this fluid up to the natural standard of weight, independent of the natural quantity of uric salts. This hypothesis is untenable, for although albumen does exist here in large quantity, still this foreign ingredient cannot have the effect of appreciably increasing its weight. It must contain nearly its usual proportion of saline matter, or the urine will fall far short indeed of its healthy weight. On the other hand, we can as reasonably conjecture, that the amount of derangement or disorganisation under which the kidney labours, must be of importance enough to produce fatal constitutional effects, when the kidney allows only a fluid to pass through, resembling pure water in its properties, and this, too, but scantily secreted, while the salts which should be thrown out of the system in the urine, are retained in the blood, there to act by their presence as a poison to the whole constitution, and produce death in the various ways before mentioned. Having thus given you my reasons for the belief I entertain of the identity of pathology and cause between these several diseases of the kidney, and the diseases of the liver after which I have named them, let us try if, on examination, we can trace any analogy between the secreting system of the kidney in its hypertrephied state, and the secreting system of any other organ in the body during the continuance of any disease which may affect the latter; or if this analogy will give us any clue to our treatment of this variety of Bright's disease? (Here he again recapitulated all the symptoms of the hypertrephied kidney, as detailed before, and concluded by stating that these symptoms had at some past time been preceded by an attack of nephritis.) He then proceeded as follows: this attack of nephritis has subsided and has given rise, in my opinion, to an atonic state of the kidney, in which its function of secretion continues to be performed almost naturally,—a fact proved by the quantity of urine eliminated, containing nearly its healthy ratio of saline matter, and at the same time its vascular system becomes so relaxed, as to allow the serum of the blood to pass through. In fact it is in a state similar to what it would be were it the subject of passive hæmorrhagy, and just in the same condition as the intestines when labouring under cholera or diarrhœa. In my opinion, this disease is nothing more than a *diarrhœa of the kidneys*. Of the varieties of Bright's disease, this is by far the most manageable, and is one, as I think—when properly treated—not productive of serious detriment to health. If one might pursue still, the analogy which I have proved to exist between it and its kindred disease of the liver, I see no reason why life should not be prolonged to as great a duration in the former as in the latter. The treatment here should resemble that for the hypertrephied liver, in which you cannot do better than improve the patient's health by tonics, and never mind interfering directly with the liver. If you meddle with it you will probably have reason to repent it, *you cannot reduce its bulk, and by your efforts to do so you may shatter the constitution irretrievably*. In this variety of kidney disease act likewise, direct your remedies, *not* to improve directly the state of the gland, the subject of disease, but to improve as much as possible your patient's state of health.

A curious circumstance frequently takes place in this disease: the anasarca disappears for a few days, when the patient fancies himself cured, but in a very short times it returns again, and this although the patient has been over and over again mercurialised. I shall relate to you an instance which occurred in my own practice a very short time since, illustrating the utility of the line of treatment which I have been recommending to you. Many others have fallen under my notice from time to time, but the case I am about to recite is the latest. In April or May last I was consulted by a gentleman labouring under the symptoms which I have detailed as characteristic of this affection. He had been attacked the previous summer; had been confined to his room all the winter, when he was bled, cupped, leeched, blistered, and put under repeated mercurial courses, without having derived any benefit from them. Reasoning from the analogy which I conceived to exist between this disease and that of the liver, which I have so often mentioned, and being aware of the inutility of the measures which had been previously adopted, I determined to try tonics with him. Of these I considered iron best, and the preparation which I selected was the persesquinitrate, in doses of fifteen or twenty minims thr e times a day in water. Under this plan of treatment, aided by a judicious regimen, he improved quickly; and no later than last week I have had a letter from him, stating that the dropsy is gone, and that his general health is excellent. I cannot say if in this case the urine is still albuminous, as I have not lately had an opportunity of determining. With regard to the power of the persesquinitrate of iron in this disease, I am not aware that it possesses any greater than other chalybeates. A more extended experience than mine is necessary to determine that. This case will shew you the inefficacy in this disease of any mode of treatment which goes on the plan of reducing acute or sub-acute inflammation of the kidney. Your best plan of treatment I conceive to be that, which by improving the constitution generally, will serve to increase the tonicity of the relaxed vessels of the kidney.

The treatment of the primary nephritis I have already mentioned. For the removal of the anasarca, which may set in after its subsidence, you may, *for once*, have recourse to small charges of mercury, assisted by diuretics; but when once the deposit of lymph has taken place within the kidney, characterised by the signs I have already detailed, lay aside all other remedies and have immediate recourse to tonics.

Cirrhosis of the kidney, when once established, I look upon as a disease wholly incurable, and quite beyond the present extent of the remedial art, as its progress is surely, though sometimes slowly, fatal. It is true, indeed, that though we cannot remove the cause of the disease, yet we can palliate some of its most distressing symptoms and complications. The anasarca we may temporarily remove by crem. tartar., digitalis, and other diuretics; the ascites by tapping, followed up by diuretics. When the head is threatened—as very often happens—we may combat the mischief by appropriate remedies; or if the chest become affected, we may give temporary relief by adopting the line of treatment proper in pleuritic effusion, or bronchitis, as the case may demand. Beyond these lines of demarcation, our treatment in this variety of kidney disease cannot travel; it is beyond our control; while in its fellow-affection, if we adopt the line of practise which has been of service in the cases and under the circumstances already referred to, I am confident, that—humble instruments of a far more mighty physician—our efforts will often be crowned with success in restoring the blessings of health, and perhaps of longevity to our sickness-stricken brethren.

Royal College of Surgeons. — Gentlemen admitted members on Friday, March 28th, 1845. —A. J. Vandenburgh, R. Bryden, P. Hudson, E. C. de Crespigney, T. C. L. Marsh, H. T. Lomax, J. E. Taylor, J. Foster, J. Moore, J. H. Gandy, and J. Atterbury.

THE STRUCTURE AND FUNCTIONS OF THE BRAIN, WITH NEW VIEWS ON THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine,

Formerly Physician to the Bicetre and Salpetriere Asylums, Author of the "Traité Medico-Philosophique sur l'Alienation mentale," "Medicine Clinique," "Nosographie Philosophique," &c., &c., Translated with Notes illustrative of some important doctrines in Physiology, Phrenology, and Moral Education.

By Dr. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c.

In another case, a young man, aged 24, of an irritable character, ready to exaggerate, either for good or evil, quits his father's house, with a little money, comes to Paris, and after indulgence in liquor, betakes himself to pass the night in a house of ill fame. During the night, he has hallucinations of hearing, which made him hear girls and men under the bed, threatening to assassinate him. He examines under the bed several times, and although he can see nothing, his false perceptions continue; he opens the window, and cries out for help; he is taken to the prefecture, and from thence sent to the Bicêtre. Three days after, tranquillity returns suddenly; he feels that he had been out of his senses, that all he had felt was a dream, illusions produced by a day's debauch, and the grief of having left his home.

In both these cases, there was a double and a simultaneous action of the encephalon, a sort of conflict between the spontaneous hallucinations of the brain, and the recollection of them which subdues them. Nothing can be more singular than this species of insanity; had it persisted, the patient would at last have believed in the reality of their false perceptions, and of this, we subjoin a few examples.

We may at first remark, that it is always the brain that perceives; it is it that sees and hears in persons labouring under hallucination, even when blind, or deaf; that perceives the pain of a leg, long since amputated; that hears, sees, smells, tastes, and feels in dreams, when all the senses are closed, or asleep, and external agents are absent.

A gentleman, aged 45, imagines that a plot is formed against him; that he is the butt of certain masonic machinations, the object of which, is to injure, and thwart him, in all his undertakings. He forms an acquaintance with a female, and imagines that she sets him to sleep by means of narcotics, for the purpose of shewing him that his dreams are realities. He flies into a passion, and commits acts of violence. His irascibility and suspicions augment against all persons, even against strangers. Here we have clearly a case of morbid susceptibility, of firm belief in false perceptions, veritable hallucinations, which henceforth form a part of this disturbed disposition. He has remained in this state for some years past.

A man, aged 65, returning home of an evening, in the month of August, 1827, hears a noise and voices that threaten him with misfortunes; he is so alarmed as to call in a neighbour, with whom he makes search of the whole house, in vain of course. During the night, he hears them again, and this continues day and night, for four months; at the end of this time he not only *hears*, but he also *sees*, the persons who continue their threats.

These persons are as light as pasteboard, inflated with air, and he can put them aside with hand or foot; they put on the clothes of the patients that sleep in the same dormitory with him. To these hallucinations of the hearing and sight, are soon superadded those of the taste, smell, and touch. He *feels* his persecutors touch and push him; he smells their bad breath, which infects his nostrils and mouth, and he takes the utmost pains, in consequence, to rinse out his mouth every morning.

During the day, the hallucinations of hearing predominate; they had persisted at the time the case was reported, for 14 months, without the slightest amendment; the mental alienation being the more incurable, as no effort could convince him of the falseness of perceptions, the contradictions of which, he evinced great ingenuity in explaining.

In this point of view, mental alienation would seem, in fact, to be in the majority of cases, but a series of hallucinations, from which it derived its most characteristic features. Let us once more recur to facts on this point.

A gentleman, of cultivated mind, but of hasty disposition, becomes convinced that his brother died from poison; he thinks that his own food is poisoned, and that, during the night, he is pricked with poisoned instruments, and that he is made to smell unhealthy odours; he hears conversations relative to the plots formed against him. His hallucinations are so strong, that he makes his physician smell the food; even his bed, and his clothes, he says, are impregnated with poison. These false sensations are unaccompanied by any other delirium; he is rational on every thing else, but completely insane on this point of his hallucinations. A year after this, he flies out into a passion when any one contradicts his ideas, he loses his sleep, quarrels with every body, and becomes violent, his hallucinations continuing as before. This state has lasted 14 years.

In another case, a man of middle stature, strongly built, experiences suddenly, at 18 years of age, the following symptoms: his intellect seems to be enlarged, the whole world seems to be unfolded to his view, he beholds the whole creation. He is pursued by ideas of religious mysticism, he goes to confession, and communion, he believes that God has designs upon him, that he gives him a mission, he hears in his stomach, words that form themselves into parables and prophecies. One night, he saw a luminous disc in the midst of a light cloud, a voice comes forth from it, saying, "The children I shall bless, shall be blessed, and those I shall curse, shall be cursed." He acknowledges the voice to be from God, and a long conversation follows. This hallucination decides his fate. He is the Messiah who will come at the end of time, and, in this quality, he endeavours to gain access to the Archbishop of Paris. He attempts to scale the walls of the Palace, and is sent to the Bicêtre. During a year, his state of monomania has not varied, but he has had no exacerbation.

Another patient, age 56, presents the aspect of a terrified person; he hears voices incessantly speaking from the edge of his bed, reproaching him with having stolen 15 francs; at first, he thinks it is a dream, but the force and persistance of the accusation augmenting, he is at last convinced that it is a reality. He changes his lodgings, but the first night in his new domicile, the same voice is heard in the chimney, at the window, and at the door. Towards morning, he says, the tumult is general, the gens d'armes are in the street, the neighbours are looking on from their windows crying out against the jesuits that have come to take him. He is removed to an asylum; his hallucinations continue for a year, when he dies in a state of general marasmus: on the very morning of his death, he attributes his difficulty of breathing to the pressure of his enemies upon his chest.

In these cases of chronic mania, we see the hallucinations play the most important part, in fact, the only one that constitutes the real delirium; we shall, hereafter, have occasion to observe their influence in suicide, &c., as well as in other cases of perversion.

Mr. M., aged 33, had, in 1826-27-28, three different attacks of periodical mania each year, which yielded easily each time. His mother died insane; his father committed suicide. He had, himself, been always remarkable for his susceptibility, thinking that others were making game of him, or amusing themselves at his expense. This original disposition grows stronger with age. Married 12 years ago, he has been separated from his wife for the last 11 years; he hears the police saying that he is a great criminal—he reads it on the countenances of the passers by—he is quite certain the newspapers say the same thing—he considers himself a lost man—he jumps out of the window, and breaks his right thigh; he is cured at the Hotel Dieu, and goes to Nantes; the calumnies precede him there. He *sees* it written on the countenances of the persons he meets, that he is a great criminal. He is so much cast down by it, that he returns to Paris. He is admitted into the Bicêtre, and dies after remaining several months in a state of chronic mania.

The following case bears a close analogy to this one, in regard to the influence of false sensation in the production of suicide.

A retired officer, aged 38, fractures both his legs in an attempt to make his escape from the fortress of Besançon; they are both amputated successfully, but he becomes gloomy, and an attack of mania follows; he hears voices abusing him incessantly, persecuting him, and threatening to shoot him; he replies to them. This state of hallucination and anxiety, lasts ten months, in spite of every effort of treatment; he is more and more concentrated in his false sensations. In order to save himself from the punishment they inflict on him, he obstinately refuses to eat anything; the *voices* tell him he must not eat. He is made to eat forcibly, by means of the tube; this operation is a great punishment to the patient. The hallucinations appear to gain strength in proportion as the powers of life are failing, and he dies after a month of almost complete inanition.

Thus, in the beginning of mania, in the prelude of other forms of insanity, in chronic, or melancholic delirium, in hypochondriasis, and the various kinds of suicide, cerebral hallucinations are, in fact, the constituent and premature elements of all the irrational acts and words of the patients; and this is as much as to say they form the very body itself of insanity.

In hypochondriasis, we observe the combined phenomena of cerebral hallucinations on the one part; and on the other, the most extraordinary illusions of the senses, and of the other organs of splanchnic cavities.

This affection, so frequent, and so variable in all its forms, and which, definitively, must be regarded as a perversion or exaltation of the instinct of self-preservation, and the love of life, in consequence of which, a man exaggerates, or imagines real or imaginary diseases, springs from two fundamental sources, which are the brain itself, in some cases: in others, the other viscera, more especially those of the abdomen.

When the hypochondriasis arises from a premature affection of the brain, the hallucinations are perfectly characterized; the brain, in such a case, perceives impressions more fine and delicate; the patient has the consciousness of circulation, digestion, and respiration, the sensibility of the skin is so keen that it feels impressions of heat and cold of which no one else can be sensible. From this cerebral super-excitation flows a series of hallucinations which might be termed physiological, seeing that they are simply the exaggeration of sensations, more or less severe.

The scene is different when the hypochondriasis arises from suffering in an organ more or less remote from the brain. Broussais, and Louyer Villermay affirm, that there can be no hypochondriasis without chronic gastritis. This statement is too absolute to be correct; it has been fully refuted by M. Fabret, who has stated most satisfactorily that in this disease, the brain is always affected, either primarily, or secondarily; he observes, however, that such patients suffer from flatulence, dyspepsia, eructations, nausea, vomiting, lancinating pains in the sides, perspirations, turbid urine, small and painful evacuations; phenomena unimportant of themselves, no doubt, but which, from the susceptibility of the patients, become a source of sensations, as false, as they are void.

REPORTS ON DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Inflammation of the Os and Cervix Uteri.

This disease may commence either in the acute, subacute or chronic form. The acute is necessarily the most marked in its symptoms, while the latter, whether from the frequency of its occurrence, the insidious mode of its commencement, or the dangerous alterations of structure to which it frequently leads is deserving of the closest attention.

Acute inflammation of the cervix uteri is rather a rare disease, and when it does occur, is either

usually in connection with acute suppression of the menses, or from acute inflammation having spread to the cervix from some neighbouring part, or where it has been the result of mechanical injury and irritation. I refer of course to the unimpregnated state, not referring to any inflammatory affection of the part which may occur during pregnancy, labour, or childbed.

It is to the chronic or subacute form to which I now allude. It is an affection of such frequent occurrence that it is scarcely possible for a medical man, even in a small and recently commenced practice, not to have met with cases of it, and it is one, with the early symptoms of which he ought to be accurately acquainted.

The commencement is frequently so gradual that at first there are little more than the ordinary symptoms of pelvic congestion. There is a feeling of pain and weight about the sacrum and loins, extending round the pelvis and down the thighs, there is a sense of fullness and sometimes heat in the pelvic cavity, and as the disease becomes more established, it is attended with distinct throbbing in the affected part extending to the rectum. The pain, throbbing and bearing down, are much increased by the erect posture, by sitting down suddenly, especially upon a hard seat, by riding in a rough uneasy carriage, by sexual intercourse, and by the passage of solid hardened fæces. In maintaining the erect position, not only is the weight of the whole column of the aorta thrown upon the pelvic circulation, which thus becomes more than ordinarily loaded, but from the same reason the blood returning by the ascending cava is proportionably obstructed in its course, and thus the congestion of the inflamed part is greatly increased. The uterus, from its vessels being thus distended with blood, becomes heavier and larger, it descends somewhat lower than usual into the pelvis; its os and cervix approach the perineum, so that even moderate pressure upon this part will be sufficient to push it against the inflamed extremity of the uterus and cause pain; the same effects will be produced by riding in a rough vehicle. "In this way," says Sir C. M. Clark, "the passage of a hard and large portion of fæces causes much distress, for not only are the blood vessels filled in the act of expulsion, but during the evacuation, constant and sometimes considerable pressure is made upon the cervix." By degrees, the pain assumes a sharp darting character, coming on in severe stabs which seem to transfix the pelvis. The catamenia become deranged; at first, perhaps they are too profuse, but they soon become sparing, pale, or discoloured: the period is preceded and attended by severe pain, which is not relieved by the discharge; the digestive organs sympathize, the appetite is impaired, the bowels are deranged, the liver becomes torpid, and the general health begins to suffer severely.

This affection is usually accompanied with a white creamy discharge, which was first pointed out by Sir C. M. Clarke as peculiar to it, and as being secreted by the glandular structure of the cervix. In a state of health this secretion is nearly, if not quite transparent and very nearly resembles the thinner portions of the albumen ovi; the colourless albuminous mucus which is so copiously secreted at the commencement of labour is from the same source. In proportion as the part by which it is furnished becomes irritated or inflamed, it assumes the opalescent milky or creamy character above described; it is a modification of this secretion which forms the gelatinous plug which fills and seals up the canal of the cervix uteri during pregnancy. On withdrawing the uterine sound in cases where irritation of this part has existed, we constantly find that the extremity of the instrument which had passed through the cervix is smeared with a thin whitish albuminous secretion, which, by means of the speculum may be seen oozing from the os uteri, and adhering to its edges.

On examination, *per vaginam* we find the vagina healthy; the finger produces no sensation of pain until we reach the os and cervix uteri, which are excessively tender, the slightest touch not only causing pain in the part, but extending over the whole uterus, and into the back. If the disease has been of sufficient standing and severity, to have been attended with lancinating pains, a sharp paroxysm of these will frequently be produced. The lips of the os uteri are swollen and painful; the cervix is evidently more bulky than natural, and beside an increased heat of the part, the finger can readily detect a general pulsation through its substance, if gently and steadily applied. The lower segment of the uterus is evidently enlarged, heavier and more solid to the feel, and the increased size of the organ may be (if necessary,) still further determined by examination, *per rectum.*

The *causes* are those which arise from the general state of the system, or those which act locally. Thus we see that whatever tends to depress the powers of the system and produce a state of atony is liable to be followed by a disposition to this disease, hence it is frequently observed to have followed long continued dyspepsia, leucorrhea, passive hemorrhage, repeated abortions, &c. The powers and tone of the system have been reduced, the uterus has become relaxed and congested with passive plethora, and its most depending portion, viz. the os and cervix, has necessarily suffered most from the engorged state of its circulation. This depressed state of the system seldom exists, without considerable derangement of the assimilating functions, a condition which I have before showed soon paves the way to local congestions, especially of the pelvic organs, and subject to occasional flushings, and exacerbations which I have already described, when speaking of the arthritic form of dysmenorrhœa.

In many cases, inflammation of the cervix uteri evidently depends upon a rheumatic gouty condition of the system; it is attended with the same renal and hemorrhoidal derangements as in other modifications of this diathesis, and is also relieved by similar remedies.

The local causes are those which act more directly, by producing irritation and congestion: thus long continued exertion in the erect posture, viz. walking, especially shortly before a menstrual period, when the uterine vessels are more than ordinarily engorged; violent horse exercise, constipation, &c. It may also be produced by the improper use of astringent injections to check uterine leucorrhœa.

The *treatment* will to a certain extent be guided by the cause, but in all cases where inflammatory action has been *distinctly* established, it will be necessary to apply leeches directly to the part itself, or to the verge of the anus. The former, where it is possible, is preferable, from its being so much more effectual. After the leeches, we should use a warm hip bath, and keep up a continuous stream of warm water in the vagina, by means of a proper injection apparatus, so as to act as a fomentation to the part and to promote the bleeding. In milder cases, the use of leeches will not always be required, and we may depend on the effects of general remedies, and the local use of saturnine and sedative injections.

A brisk dose of calomel is frequently desirable in the first instance, after which the deviations of the general health from the natural standard must be treated according to the circumstances of the case and will be best illustrated by the following reports.

S. T. æt. 30, three times married, mother of 2 children, the youngest 11 years old.

April 2, 1835.—Complains of severe pain in the right groin, increased by sexual intercourse, which also induces considerable suffering in the pelvis and loins; complains also of painful dragging and bearing down with shooting pains in the breast, and severe pain in the pelvis when passing fæces.

Examination per vaginam.—Vagina somewhat relaxed; os uteri low down, cervix rather hard, and very painful. Has had copious leucorrhea, and a considerable quantity of white creamy discharge.

℞ Pil hydrarg. chlorid. co. gr. v. o. n. ad quartam noctem.

℞ Magnesiæ carb. gr. xv. magnesiæ sulphatis, ℨss. ex aquæ menthæ pip. ℥iss. o. n.

℞ Liq. Plumbi. diacetatis. Tinct. opii aa. ʒii. aquæ distillatæ ℥viij. M. ft. injectio.

7th.—Feels easier, and better in every respect; no discharge; still some pain of back; appetite good; bowels much purged; the catamenia which ought to have appeared yesterday, have not come on.

℞ Pulv. rhæi. gr. v. om. nocte in formâ pilulæ. Rep. lotio.

12th.—No discharge. Rep. Pil. Haust. magnes. sulph. et carb. et Lotio. She continued to improve, and ceased to attend at the end of the month.

M. A. M. æt. 44. A widow, mother of six children.

23rd June 1835.—Complains of pain in the loins, with occasional difficulty in passing water, and when the bowels are confined, she has severe pain in the centre of the pelvis, shooting into the groins and thighs; has a discharge of albuminous creamy fluid from the vagina, has been subject to leucorrhea for many years. The abdomen is large, complains of weakness.

Examinatio per vaginam.—Os uteri rather swollen. Cervix very painful when touched; I thought I could feel a distinct throbbing in it: the uterus is large.

℞ Pil. hydrarg. extr. gentianæ, aa. gr. v. om. nocte.

℞ Magnesiæ sulph. ℨss. magnesiæ carb. gr. xv. o. m. ex aq. menthæ pip.

℞ Acid. nitrici dil. tinct. hyoscyami aa. m. xv. aquæ menthæ pip. infusi gentianæ. co. aa. ℥ss. M ft. haust. bis die sumendus.

30th.—Feels better; has lost the sensation of sinking, but still complains of pain in the back and loins.

Pergat. ℞ Liq. plumbi. ʒij. aquæ distill. oj. M. ft. lotio in vaginam injicienda.

July 27.—Feels much stronger; pain greatly diminished; abdomen smaller; pergat.

I have put these cases together from their being similar in many respects. In neither was the application of leeches deemed necessary, and the symptoms yielded under a course of alterative and tonic medicine, with saline laxatives, and the injection of lotio plumbi. Mild doses of mercury are of great use here; they seem to unload the portal circulation, and, with the assistance of laxatives, clear off intestinal accumulations, which, from the pressure they exert on the pelvic organs, necessarily tend to produce uterine congestion.

I have endeavoured to select the above two cases of inflammation of the cervix, as little modified as possible by other affections, but this is not easy to do, as, in most instances, the case is more or less complicated with derangement of other and neighbouring organs.

M. H., ætat. 32, mother of one child, which is ten years old. Face pale and sallow.

January 13, 1842.—Much bearing down pain of back and loins; has difficulty in passing water, although she has a frequent desire to do so. Leucorrhœa of long standing. Pain on sitting down suddenly, and during the passage of solid fæces. Her symptoms have increased during the last six months, since which the pain has been occasionally of a lancinating character. There is no particular derangement of the stomach, or of the bowels.

Examinatio per vaginam.—Vagina loose and flaccid, especially anteriorly. The os and cervix uteri are not harder than natural, but hot, and very painful to the touch.

℞. Extr. taraxaci extr. lupuli aa. gr. iv., pulv. ipecacuanhæ, gr. ij. M. ft. pil, ij. omni nocte sumendæ.

℞. Liq. plumbi diacet, ʒij., decoct. papav., ℥viii., M. ft. lotio, in vaginam injicienda: hirudines, v. ori uteri.

Jan. 20.—Leeches bled profusely, and one large coagulum came away; feels very much relieved; her appearance is greatly improved, and the sallowness of face has disappeared; has had no darting pains or discharge since the leeches were applied; no uneasiness about the bladder, or difficulty in making water; bowels rather confined. Rep. pilulæ et lotio.

℞. Magnes. carb. sulphuris precipitati, aa. ℥ss., M. ft. pulv. sumat cochl. min. j. ad iss. om. mane ex aqua.

In this case the inflammatory symptoms were more marked, and had probably been of longer duration; hence, they were not only severer than in the two former cases, but were assuming a

more unfavourable character from the presence of lancinating pains. The irritability about the bladder showed, also, that this organ was beginning to sympathize with the uterine affection, and that the neck of it was, in all probability, more or less compressed by the swollen uterus, as evinced by the difficulty in passing water. As there was but slight gastric derangement, I prescribed the pills more as a placebo than anything else. The leeches acted well, and were followed by complete relief; and it is not more than reasonable to suppose, that but for the effects which they produced, the inflammatory action would have continued, the lancinating pains would have increased, and the cervix ultimately would have become involved in scirrhous induration. The powder of sulphur and magnesia was ordered, not merely from its acting so gently upon the bowels, but also to relieve the disposition to hæmorrhoidal congestion which so invariably exists in these cases.

S. A., ætat. 34. Mother of eight children.

March 30, 1868.—Complains of sharp darting pains transfixing the pelvis, and becoming worse towards night; they are much aggravated by constipation, and by the approach of a catamenial period. Much irritability of bladder, with considerable difficulty in passing water. Has had leucorrhœa for some years, and occasional discharges of blood from the vagina, but how far they are connected with the catamenial discharge, does not appear very distinctly from her account; has much pain when the bowels are open, and when she sits down suddenly, nor can she bear a soft seat, from its forcing up the perineum against the tender part; much bearing down pain; appetite bad; bowels regular. Dates her complaints from her last confinement, three years ago, which she states to have been severe; first noticed the darting pains about six months after, since which she has had a continued yellowish discharge. These symptoms have increased until the present time.

R. Ext. hyosc. ext. gentianæ, aa. gr. v. o. n.

R. Lotio plumbi c. decocto papaveris.

April 5.—Not much better, either as to the pains or the discharge.

Examinatio per vaginam.—Cervix uteri hard, swollen, and painful; uterus somewhat enlarged. Hirudines, viii. ori uteri.

R. Pil. ferri comp. ext. hyoscyami, aa. gr. v. o.n. Rep. Lotio.

April 21.—Leeches bled profusely, and with great relief: has had only two or three darting pains since they were applied, viz., just before the appearance of the catamenia, which took place on the 10th ult.: the menstrual discharge was free and regular in every respect. Bowels natural, but somewhat confined.

Rep. pilulæ et lotio. R. Ol. ricini, p. r. n.

June 7.—Has had no return of the darting pains. Her health has continued to improve, and she has gone on with the same medicines.

This was a still severer case than the last, not merely as shown from the suffering produced by pressing on the perinæum in the act of sitting down, and by the passage of hardened fæces, both of which were much increased shortly before the appearance of the catamenia, but also by the greater intensity of the darting pains, which formed a very prominent feature in her case.

She was one of my first out-patients at St. Bartholomew's, and as the necessary arrangements for leeching the os uteri, &c., had not then been made, I did not even examine *per vaginam*, feeling satisfied as to the nature of her complaints from the marked character of her symptoms.

The examination on the 5th showed that the cervix was becoming hard, as well as painful, and eight leeches were now applied. Their effects were as striking as in the previous case; the darting pains ceased, and when I saw her, in June, it was for the purpose of expressing her thanks for the complete relief which she had received.

I cannot but think that the threatenings of commencing schirrus were still more distinct than in the previous case, and, but for this timely check, would inevitably have paved the way to organic disease.

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.

Physician to the Birmingham General Dispensary: formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c, &c.

(Continued from page 526)

Out of numerous examples, derived from personal investigation, I give the two following, as the nearest approach, in my opinion, to the composition of the leading varieties of matured tubercle.

Fatty matter, with oil globules ..	15·9
Gelatine	6·4
Phosphates, Sulphates, Muriates } Lime, Soda	11·2
Carbonate of lime, a trace	
Oxide of iron, a trace	
Albuminous matter with fibrine..	65·2
Loss	1·3
	100·0

Fatty matter, with oil globules ..	7·4
Gelatine	11·8
Phosphates, Sulphates, Muriates } Lime, Soda	2·5
Albuminous matter	76·9
Loss	1·4
	100·0

DISTINCTIONS BETWEEN TUBERCLE AND PUS.

Pus in its natural and fluid state, can never be mistaken, even by an ordinary observer, for tuberculous matter in any of its varieties. But complete pus bears so close a resemblance to matured tubercle, that by the naked eye it is not possible to distinguish between the two. Microscopically, it has been pretended that there are minute and "constant" shades of difference which mark tubercle and pus. Lebert says: "the elements of concrete pus never resemble those of tubercle."(1) The corpuscles of tubercle, according to this author, are from 1-200th to 1-300th of a line in diameter. They contain molecular granules of from 1-1600th to 1-800th of a line in diameter, "but never," says he,(2) "true nuclei, which are so constant in the globules of pus." Now, as regards the size of pus globules, the best microscopists agree in rating them at from 1-160th to 1-250th of a line in diameter; they are often to be met with of much smaller dimensions, and Lebert himself states the diameter of the molecules to be from 1-800th to 1-1600th of a line.(3) So that in point of size, we discover little or no difference between either the corpuscules or the granules of tubercle and pus. As for the centralization of the granules, which has been represented as peculiar in the globules of pus, I am satisfied that these granules are too often found out of the centre of the globule, and much too often attached to its periphery, to render such feature at all worthy of notice. And again, distinct nuclei and nucleoli have been found in some specimens of tubercle, by Mr. Gulliver,(4) which fact of itself would render this test of distinction between the two fluids utterly fallacious.

I am fully satisfied, as well from comparing the observations of different microscopists concerning concrete pus and crude tubercle, as from personal inspection of them, that the alleged distinctive appearances of the two, if not altogether fanciful, are by no means to be relied upon in diagnosis.

Chemistry affords us some little service in discriminating between pus and tubercle, but this service is unfortunately not constant. Gelatine is commonly found in tubercle, and has never been, as far as I am aware, discovered in pus. I should not hesitate to pronounce upon the nature of any substance having the external aspect of tubercle, and containing gelatine. This test, however, is liable to the objection, that, in some specimens of tubercle, gelatine is wanting.

The other constituents of pus and tubercle, do not, according to my own observations, furnish any source of distinction between the two secretions.

In so far as the tests of crude tubercle and solid pus relate to the diagnosis of lung diseases, the want of accuracy and definitiveness is happily of little consequence. It is seldom that concrete pus is found to be a constituent of sputum.

Whenever pus is secreted by the lining membrane of the trachea or bronchi, it is either discharged in its fluid state alone, or in intermixture with mucus and other materials derived from the air passages. I do not remember to have seen an instance of pus so secreted, being retained *in situ* long enough to become concrete and to resemble crude tubercle. Again, the pus secreted by the false membrane of a vomica, is always discharged in a more or less fluid state; but should it by any accidental circumstance be retained and rendered solid by the absorption of its watery parts, so as to be made undistinguishable from matured tubercle, the fact would be of trivial consequence, inasmuch as physical diagnosis would be a security against any error as to the real nature of the case.

The only two probable sources of difficulty in the question before us, are, inflammation of the lungs terminating in abscess, and secondary purulent deposites in the lungs. Fortunately, however, these cases are of rare occurrence, and of easy recognition.

Pneumonia terminating in abscess is what few practitioners have ever an opportunity of witnessing. I never saw a case of it in my life. The examples of Baillie are rare instances of error on the part of that observant physician. Laennec met with but one case in twenty years of his extensive practice. Broussais saw but one case of ulcerated lung without tubercles · the inflammation arose from the presence of a musket-ball which had been lodged in the lungs for six years.(5) Dr. Bright's voluminous work contains but one example.(6) It is, therefore, barely within the bounds of possibility, that the suppurative product of partial pneumonia, limited to an abscess, may be retained *in situ* sufficiently long to become solid and cheesy-looking, and may subsequently be discharged with other matter of expectoration. But even in such case, the previous

It may be excepted, however, that the pneumonia of phthisical subjects sometimes terminates in the formation of sinuous abscesses of the lungs. But I am of opinion, that whenever this happens, the tissue which has been destroyed, and its place occupied by pus, was previously the seat of tubercular deposition, or was in some sort degenerated. The abscesses are always burrowing and connected, which is not the case in genuine pulmonary abscess, and the pus which they contain is thin, curdy, and scrophulous. Cases of this kind are recorded in which no traces of distinct tubercle could be found in the lungs. Dr. Graves relates one of a man whose "lungs were extensively solidified, black, and ulcerated, containing several sinuous cavities filled with pus of a scrophulous character, but not a single distinct tubercle. There was not the slightest vestige of the chief kind of tubercle, the yellow one, nor could we find any of the small miliary transparent kind; the whole mass was solid except where it was suppurating, evidently the result of phthisical pneumonia."—Clinical Medicine, p. 280.

(6.) "The lung itself was pervaded by several small sloughing abscesses; of which three or four, of the size of a hazel-nut, occupied the lower lobe so externally as immediately to come into view, these were surrounded by a thin cyst, and filled with dark olive-green putrid matter: the surface of the lung above them was of a yellow colour, in a well defined spot; there were others deeply imbedded in the substance of the lung, and one or two near the apex in the upper lobe; the lung around these sphacelated abscesses was very nearly healthy."—Reports on Medical Cases, p. 31.

and present symptoms of the patient, aided by the signs of auscultation, would enable us to judge accurately of the nature and extent of his ailment.

Secondary purulent deposites in the lungs, though more frequent than pneumonic abscess, are by no means common cases. The pus also, is rather diffused through the pulmonary tissue than collected into one mass. After an indefinite period of detention, if the patient recover, it is generally by an absorption of the purulent matter, with or without inflammatory symptoms. Should the pus chance to be detained in a single spot, and should it afterwards be expectorated in a solid form, leaving a cavity in its stead, we must be satisfied, if chemistry do not avail us, to found our diagnosis upon the patient's history, and the nature and number of his present symptoms.(7)

VARIETIES OF SPUTA.

The various appearances which expectorated matter presents in diseases of the respiratory organs, have frequently suggested its classification into distinct varieties. I believe the attempt to enumerate and define them was first made by Rosen.(8) He says. "ac differt excretorum(a) *quantitas*, eaque iisdem temporum intervallis major vel minor (b) *qualitas*; et tum quidem diversa humorum corporis vel sanorum, vel corruptorum, excreta apparet species, et quidem (1) *Sanguinea* ut in hœmoptysi, et tussi quoque aliquando convulsiva. (2) *Purulenta*, ut in ulcere pulmonum, vel phthisi. (3) *Mixta* ex his, ut in peripneumonia, et anginâ suppuratâ. (4) *Serosa*, ut in tussi catarrhali, hectica, convulsiva infantum epidemica &c. *Consistentia* sic, quæ in phthisi acuta et suppurantibus reliquis pectoris affectibus excernitur materia, tenuior est, et spumida magis, quam quæ in chronica phthisi, et convulsiva tussi tenax extunditur colluvies. *Color*, flavum nempe, et semicruentum, peripneumonia et angina suppurata exhibet; dilutè croceum, vel et flavum, convulsiva tussis infantum, ut et illa quæ in morbillis adest. Lividum, cineritium, pallidè livescentem, atrum denique, vel viridem phthisis. *Discolorem*, vomica pulmonum. *Odor*. Fœtorem spargunt, quæ phthisi et vomica pulmonum laborantes tussiunt: inodorus autem ille fere humor est, qui catarrhali et hectica tussi pullulare solet."(9)

(7) Amongst the pathological appearances of glanders, both in the human subject and in the horse, abscesses of the lungs form a conspicuous and not uncommon feature. A remarkable case occurring in the person of a man who died in fourteen days after having been bitten, and whose "lung was found filled with abscesses," is quoted in the Lond. Med. Gazette, Sept. 13, 1844. p. 816. But I am not aware that in such cases there is ever any expectoration of either fluid or concrete pus. And even were such expectoration to occur, the concomitant symptoms would render the diagnosis easy enough.

(8) Previously, however, to the time of Rosen, Burnet treated somewhat pertinently of varieties of sputa, under the denomination of *humores*; as *humor pituitosus, humor insipidus, humor acidus, humor salsus, humor acris*, and *humor subdulcis*.—(Thesaurus Medicinæ Practicæ, ed. 1698, p. 201.)

(9.) De Tussi. Ext. in Haller, Disp., tom. 2, p. 59-60.

(To be Continued.)

The *Times*, in one of its city articles, speaks of the extraordinary success which has marked the treatment of African fever by Mr. W. Daniel, M.R.C.S. It appears that his first voyage to the coast was marked by the ordinary disasters, but adopting subsequently a new plan of treatment, he has voyaged far into the interior, and twice lay on its worst coasts without a single death out of numerous ships' crews. We are happy to say that we are likely, on an early day, to be able to give this able surgeon's plan of treatment.

We understand, on the best authority, that the numerous contributions of Mr. Ancell to the *Lancet*, whether they assumed the editorial form or not, were in no case a source of emolument to the author. This is a matter, which while of interest in relation to the management of journals, should be mentioned as an act of common justice to Mr. Ancell.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES—MORBID AND HEALTHY,

By Dr. KNOX, F.R.S.E., F.R.C.S.E.,
Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

GENTLEMEN,—One of the most remarkable of human functions is that of locomotion, or the obvious and sensible motions of the limbs and trunk; the infinite variety of movements performed by the limbs, and the transporting the whole body from place to place. The organs by which these most important functions are performed, are the passive organs of motion, namely, the bones and joints—the active organs of motion —the muscles. These, it is true, are regulated by the nerves, as shall be afterwards more fully explained; but, in the mean time, I shall consider with you in the first place, the anatomico-physiological history of all these organs conjointly and severally, reserving the question of their internal tissue for that division of our lectures when all the tissues of the human body will be minutely and carefully examined. Before we look microscopically at any object, let us endeavour to ascertain what circumstances and what facts on it, or about it, are perceptible to the naked eye; the functions of the human lens were discovered without the aid of any microscope, and a knowledge of the exact inclination of the pelvis does not supersede, it is true, but takes the precedence in every sense of all enquiries into the microscopic structure of the broad bones of the pelvis or of any other bone whatever.

Osseous System.—The passive organs of motion. A careful examination of the human skeleton must precede every other kind of anatomical and physiological research—not only of the skeleton generally, as it is first offered to the gaze of the student, but of each individual bone. First comes its descriptive anatomy and the more enumeration of the processes and foramina, elevations and depressions of each individual bone, &c.; and then must follow those other physiologico-anatomical observations which in point of fact constitute real practical physiology:—physiology, as understood by the sound practical surgeon and physician—misunderstood and entirely unknown to those who imagine physiology to be something abstract—a something having nothing to do with the practice of the arts of physic and surgery. A highly intellectual student and careful observer, unprejudiced, and a lover of truth, assured me lately that for nearly a year he had been watching the practice of a distinguished chemical physician, and of another who had lectured on what he called physiology for twelve or fifteen years in a public northern hospital, and to the best of his recollection, the diagnosis in every second fatal case proved false upon dissection! This is a necessary and a lamentable consequence of separating physiology and pathology from anatomy—men otherwise sound by following this course are sure to fall into empiricism, or to become homœopathists.

The bones (ossa) are the hardest parts of the body: liable to fracture; inelastic; of a dull white colour, and insensible. When dried they retain their form, provided they be adult bones—that is, have attained their full growth—and they resist putrefaction. Nevertheless, bones rot readily enough when placed in jars of cold water in these climates during winter; in a cold apartment bones will not macerate so as to clear; they rot and become useless, or at least spoiled for anatomical purposes. When buried in the soil they seem to resist decomposition equally with the bones of other animals; hence, it is inferred, that man must have appeared on the earth subsequent to the Mammoth, the Saurian, and many other epochs, seeing that no *fossil* remains of human skeletons have ever been found. Calcareous salts, (phosphate of lime, carbonate of lime) deposited in an animal cartilage, constitute their composition and texture, to which must be added, blood vessels of all kinds, perhaps some nerves, membranes, cellular tissue, fat; the calcareous salts may form about a third of the entire substance. The ancient division of the tissue of bone into compact and spongy, and also reticular, has its practical interest, although some pathologists, as the illustrious Scarpa, have thought it, or seemed to think it, of but little moment. It is obvious to the naked eye, and it scarcely requires to be pointed out to the student, where he will find the compact tissue, and where the spongy or cellular. The cells of the spongy parts of bones communicate freely with each other, as may be proved in a variety of ways; by boring the extremities of the bones, and throwing in water with a syringe; by passing quicksilver through the bone gravitating by its own weight, &c. It is enough to say that birds have air cells in their bones, to shew how specifically distinct they must be from the human bones, and how incorrect all inferences must be from experiments made on one, and applied to the other; hence the errors of Troja, Macdonald, and a host of others, who experimented on the bones of pigeons and other birds, drawing conclusions from such experiments, which they unhappily applied to man.

In the interior of the human bones is the marrow (medulla ossium) composed of a soft semi-fluid fat, a membrane enclosing its cellular tissue and blood vessels. It fills all the cavities, as well those in the interior of the long bones, as those found in their extremities, and in the spongy tissue, or diploe of the flat and short bones. The membrane investing the exterior of bones is called periosteum, respecting which two extreme opinions have been held; the one regarding it as a most important organ, not only nourishing, but originally forming the bones, and restoring them when either partially or even wholly destroyed, as in the disease termed *necrosis*; others regarding it as merely composed of cellular tissue, and unimportant, excepting in so far as it conveys the nourishing vessels to the bones. The soundness of these opinions we shall consider at great length hereafter. The student may, in the mean time, observe, whilst carefully clearing the exterior of the joints in the practical rooms, that the periosteum does not invest every part of the bones; that it quits them near the joint where the cartilage of incrustation covers the bone proceeding externally to the synovial capsule, investing it, as it were, and thus going on to unite with the periosteum of the next bone. This shews a continuity of the periosteum, which Bichat was desirous of establishing. With continuity of structure, there may be continuity of sympathies, morbid and healthy. Further, the periosteum dips into the outer layers of the bones, sending almost innumerable prolongations into the osseous tissue. Of these, many are intended to support the vessels, but others have not that character: the periosteum is usually considered to be a fibrous membrane, insensible though vascular; it is admitted that it receives nerves derived from the sympathetic system. The osseous canal passing into the interior of the long bones, and lodging the nourishing artery so called, will be carefully described when speaking of each bone.

Whilst examining the fresh bones, and noting these peculiarities in respect to them, on which ultimately all sound physiological knowledge is to be based, the student may, for a moment, attend to the cartilages (cartilagines), so intimately united anatomically and physiologically with bone itself. This is the order followed by the authors of the *Encyclopedic Anatomique*, a work which may be considered as expressing on most points the latest received opinions.—The basis of a bone, as you see, by these preparations, is a cartilage, as may be proved by exposing the bone to the action of fire, when fully a half of its weight will be driven off; the animal part strictly is so driven off, and the calcareous salts remain, the bone meanwhile retaining its form; or a bone may be immersed in an acid liquor, when it will again lose about half its weight, but this time the animal substance, or the cartilage remains, and the calcareous salts are removed by the menstruum. Preparations exhibiting these useful physiological facts are common in most museums; but we need not dwell in this lecture, on a subject which falls to be discussed at considerable length hereafter.

Other cartilages exist beside those forming the basis of all bones; these are the *persistent carti-*

ages, whose history, according to the learned authors of the *Encyclopedie*, ought to belong to the osseous system, by reason of their intimate union with that system. This is a more difficult question than at first appears; there are persistent cartilages, no doubt, such as the costal cartilages already exposed by the student whilst dissecting the intercostal muscles and walls of the chest, which, generally speaking, though not always, do persist to a late period of life; but even these become ossified: so do those of the larynx, and this so frequently as probably may have led Beclard to call them—the "thyroid bone," "the cricoid bone,"—terms new in anatomy, and never so far as I know, adopted even by the transcendental anatomist when speaking of the human form. The permanent cartilages of the nose and ears, on the other hand, never ossify, or very rarely, and may then almost be viewed as a pathological circumstance. I shall then allude here merely to the *costal cartilages*, structures, which the student of a single winter's study ought to have examined for himself. They are white, elastic, opaque, and much less abundantly provided with calcareous salts than the bones; a membrane encloses them, called, *perichondrium*, analogous to the periosteum; of a structure almost homogeneous, or, at least, scarcely fibrous. When dried they become translucent, hard, brittle: blood vessels no doubt they must have, and, perhaps, nerves, but this is very doubtful. Of the fibro-cartilages connecting the vertebræ especially together, I shall say little at present. They are fibrous and cartilaginous bodies, remarkable for their strength and elasticity; a yellow substance, or ligament of great power will be found connecting the laminæ of most of the vertebræ; it also is fibrous; its interesting history will be given afterwards. Let us now return to the osseous system, as viewed not with a reference to its intimate structure, but with a view to the right comprehension of the function of locomotion in man, and of the physiological history of the human skeleton.

The ancient division of the bones into long, broad, and short, or mixed, led to nothing; even admitting that the long bones possess in the interior of their shafts, a cavity of more or less ample dimensions, modifying, no doubt, a little, the pathological condition of such bones. The assemblage of bones is denominated skeleton; natural, if their own ligaments have been suffered to remain; artificial, if connected by means of wires, or in any artificial manner. Sœmmering justly remarks that the practice of drying young skeletons or settling them if dried, is altogether improper, and that such skeletons ought to be preserved in spirits—no doubt they should—but even the dried up young skeleton shews many interesting points in the osteogenesis or growth of bone, which could not well be made out otherwise. The germs of the growing bone cannot, indeed, be well seen until the young skeleton has been thoroughly dried: if immersed then in turpentine, it becomes a valuable preparation. All anatomists have referred to the dried skeleton for the history of the osteogenesis, but I quite agree with Dr. Sœmmering, that by this process, the form of the bones is entirely altered, and ought not to be placed before the anatomical student, without a proper explanation of the objects held in view in the preparing such specimens. It is also admitted, by this method, they lose about an inch of their height from the contraction of the fibro-cartilages.

The number of bones in the adult skeleton, are, in the head, 22; hyoid bones, 4; vertebral column, say 33,—that is, counting the sacrum as composed of 5 bones and the coccyx of 4, ribs 24, sternum 1; ossa innominata 2; in the upper extremity, 31, not reckoning the sesamoid bones, which are yet as constant as any in the body; in the lower extremity, 26, exclusive also of the small sesamoid bones—making, in all, about 200. Every anatomist takes his own view of the matter, which is not indeed of the smallest moment.

In respect to the average weight of the skeleton, it is not easy, for obvious reasons, to arrive at anything like a good approximation to truth. It is said in man to average from 150 to 200 ounces, and in woman from 100 to 150. The actual weight and the average weight of about 260 crania, including the upper jaw, will be given when we consider the history of that part of the skeleton.

In a general sense, the human skeleton is symmetrical—that is, the bones placed in the mesial line or plane may be divided into two equal parts, resembling each other more or less straightly. In respect to the bones placed laterally or not in the mesial plane, they resemble each other also; so that the skeleton is in this sense symmetrical. This, however, must not be understood literally, for there never, perhaps, was a human skeleton strictly symmetrical; remarkable deviations from symmetry are extremely common, but in general they do not go to any very great extent, the laws of a-symmetry being checked, as it were, by the tendency to symmetry, and thus materially balancing each other. The more remarkable deviations from symmetry, whether congenital, strictly pathological, or produced by mechanical means, will be carefully noticed as we proceed with the history of the skeleton.

Of the growth of, and changes in, the form of the bones.

The changes which the human skeleton undergoes from its earliest period to old age may be divided into two stages: first, its history prior to birth; secondly, the lengthened period subsequent to that event. Here we shall limit ourselves to the condition of growth after birth.

Meckel, Beclard, and a host of anatomists, as well before as since their era, have given this with much exactness; the latest account is that of Sœmmering, whose general accuracy may be entirely depended on. "At birth the ossicula auditus are said to be fully developed; also the labyrinth and the cavity of the tympanum." This I think somewhat doubtful, as regards the cavity of the tympanum. The next best developed bones, after these, are the clavicles, the ribs, and the lower jaw. A final cause has been assigned as a reason for this without the slightest foundation. Next come the bones of the cranium, with the exception of the ethmoid, but still they are all very imperfectly developed; the frontal bone is composed of 2 portions, the spheno-occipital of 9, the temporal of 2; but this enumeration by Sœmmering cannot be exact; at birth there must be at least 2 portions composing the temporal bone, and soon after a 4th will be added. In examining the physiological history of the individual bones, these points will be more minutely attended to. In the face we find at birth the lower jaw-bone composed of 2 portions; the rest of single portions, or nuclei. The scapulæ of 4 portions each, but the epiphyses seem quite cartilaginous; the vertebræ of 2 portions each; in the sternum are 6 or 7 nuclei, or germs of bone, or points of ossification, as they are called. In the long bones the shafts alone shew the osseous structure; the ossa innominata have each 3 separate portions; what Sœmmering says, or seems to say, of the metatarsal, metacarpal, and first and second phalanges of the fingers and toes seems to me incorrect. He thinks them composed of 3 portions, and the 3 phalanges of 2. Of the tarsal bones the os calcis and the astragalus and the cuboid alone present points of ossification; the carpal bones are cartilaginous, and in this condition is the rest of the skeleton. The teeth enclosed in the jaws are without roots, and of many not a trace may be seen, at least, as regards any hard parts.

After birth the bones grow at irregular intervals, like the soft parts, more or less rapidly; they have their sympathies, as to growth, like all other parts of the body. It is usual to say that at the age of 15 or 20 years they acquire their full development, but this is manifestly incorrect; the osseous thorax takes on long after that age a manifest increase of capacity and strength in most men; the pelvis probably in women. Even in stature, the female grows to 27 and the male to 36; so that all that has been said about puberty being the period of full growth is quite inaccurate and based on coarse observation.

During the first year after birth the cranial sutures begin to form by the gradual increase of the osseous plates; these approach each other, encroaching on the cartilaginous basis. At first they more resemble mere lines slightly zig-zagged, a character which in many crania of the dark races they preserve throughout life, at least to a certain extent; this line, however, soon becomes deeply serrated in most crania—more so, however, on the exterior surface than internally; in the mean time the diploe is forming and the bones thickening. The inner table seems to be moulding itself on the contents of the cranium, the brain, and vessels, and taking the impressions from them; whilst the outer table at particular points begins to shew prominences, processes, and depressions, some of which are seemingly connected with the attachment of muscles; others, on the contrary, have no such relations. Lastly, cavities containing air which they receive from the exterior, form between the tables of certain bones, some earlier, others later, as will be explained more fully when we investigate the history of each bone. It is usual to say that the cranium arrives first at perfection, and afterwards the face; but this merely means that the bones of the face continue to grow and enlarge in all dimensions after those of the cranium have attained their full growth; even this I partly doubt; the diploe of the cranium, especially in woman, seems to me to become thicker even after 27, by which time the bones of the face have probably attained their full growth. There is a notion in some parts of Germany, that the cranium receives an additional layer of bone in woman after every child-birth; this idea it would be difficult to verify or refute; many crania of woman about 30 years of age are of remarkable density and comparative thickness.

The sternum at birth presents several germs or nuclei, and grows irregularly, continuing to present many individual varieties. The heads of the ribs are, for many years, cartilaginous, and the vertebral column also remains imperfect. I have seen the long bones attain what seemed to be their full size, and when the person must have been at least 21, and all the epiphyses of the femur were still quite separated from the shaft, that is united only by cartilages. The osseous tissue in the bones I speak of, seemed perfectly healthy. At last, however, these epiphyses do unite to the shaft, so as to form but one with it, nor can the eye distinguish any difference in texture between what was epiphysis and shaft. An opinion, however, lately thrown out by my esteemed friend Mr. John Goodsir, would lead us to suppose that these portions of the bone are even then in their nature essentially different. This opinion, in so far as I rightly comprehend it (for as yet I have not seen any printed communication on this matter,) is, that in necrosis of the shaft of a long bone, new bone to enclose the dead shaft, never grows from any portion of the bone which once was an epiphysis. If this be his opinion, I will venture to state, that although generally true, it is not universally so; but it would be out of place to discuss this opinion at any great length in this lecture. All anatomists admit that the bones undergo constant changes throughout life. At puberty the greater number of them are still incomplete, or partly cartilaginous, whilst even those called complete are far from being so, seeing that long after puberty they continue to strengthen, and to become denser, harder, and heavier. The bones which at puberty are admitted by all to be incomplete, are the six cervical vertebræ, the clavicles, the ribs, the sternum, scapula, humerus, cubitus, and radius, the bones of the hand (those of the carpus excepted) and all those of the lower extremities, (the rotatæ and tarsus excepted). The rotatæ are completed pretty early, and the sesamoid bones ossify early, contrary to the assertion of some practical surgeons.

The bones once completely formed at 36 in the male and 27 in the female, do not for a while undergo any very sensible change, still they cannot be said to be at rest! nothing is absolutely at at rest in the living body; having attained their full growth, they begin to decline; to waste away in fact; to become thinner. The sutures of the cranium run together; the vertebræ flatten; the head of the femur sinks to a level with the trohanter major, or even beneath it; the alveolar processes at last cease to be nourished, and disappear; then the teeth losing their support fall out; the

sinuses in the cranial bones enlarge, so also in the medullary cavities of the bones; but these changes, together with the proofs of perpetual vital activity in the osseous system, and the differences produced in the skeleton, by age, sex, race, we shall consider in our next lecture.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By Sigismund Sutro, M. D.

On the Efficacy of the Dried Bark of the Rhamnus Frangula as a Substitute for Rhubarb.—So far back as the days of Matthiolus, we find the bark of the Rhamnus Frangula spoken of in the following terms, as "exsolvens, roborans, adstringens; quod etiam hydropicorum aquas ducit." He also warns against the use of the fresh bark, as causing severe nausea. By more modern writers it has been styled "rhabarbarum plebeiorum." Within the last eighty years, this valuable, indigenous remedy has been allowed to fall into neglect. The author's attention was first directed to it by finding it the active agent in a nostrum for the cure of hæmorrhoids. Since then he has used it for the last twelve years, in venous, abdominal, plethora; habitual constipation, hæmorrhoids, and hæmorrhoidal congestion. It operates both by stool and urine, causing the discharge of a quantity of mucous fæces, and of blood from the vessels of the rectum. On account of its diuretic properties, it has been successfully used in dropsy. The writer has proved its cathartic powers on his own person for the last ten years. The form in which he employs it is the following:

℞ Corticis desiccatæ rhamni frangulæ, ℥iss
Aquæ puræ Oij
Coque ad octarium, dein adde sub finem coctionis
Cort. aurantii
Sem. carui contusor: aa, ʒiij
Amoto decocto adhuc fervente, stet materies donec frigescit.

A cupful of this decoction taken over night usually procures the discharge of several mucous stools. Should it, however, fail to produce catharsis, an ounce of Epsom salt may be added to the quantity of decoction ordered to be prepared at once. Should the dose, directed above, fail to procure stools the morning after its administration, it must be repeated about 11 o'clock a.m. In persons of irritable weakly habits, and those whose constitution is not familiar to the medical man, smaller doses of the decoction than that just mentioned must be commenced with. In chronic constipation, the remedy must be persevered in for some time—seven or eight weeks at least—before the obstruction is completely removed. In the treatment of hæmorrhoids by the decoction of the R. frangula, the writer prefers adding to the bark two ounces of Achillea millefolium, in place of the usual adjunct of four drachms of orange peel. Such a combination he has found exceedingly useful in the cases above mentioned; and yet more so, when to each dose of the decoction from thirty to seventy drops of laurel water were added. Should symptoms of hæmorrhoidal inflammation at any time require to be combated, the writer has found the addition of an ounce and half of sulphate of soda quickly successful in overcoming every sign of congestion.—*Dr. Gumprecht, in Hannover Annalen.*

Preparation of Iodide and Bromide of Silver.—These salts may be quickly and easily prepared, by precipitating in the dark, a solution of fused lunar caustic, with iodide or bromide of potash or soda, receiving the precipitate on filtering paper, washing it repeatedly with distilled water, and finally drying it on white filtering paper, spread over a chalk or porphyry flag. Thus procured, these salts are of a yellowish colour, and in appearance flocoy. Diffused or direct sunlight, exerts over these salts a decomposing power, reducing them to the state of black oxyde.—*Buchner's Repertorium.*

Pommade against Baldness.

Buchner's Repertorium.

Stearoptine in the Oil of Imperatoria Vulgaris.—Kallhofert placed 9 drachms of this oil in a deep cold cellar, taking care to guard against evaporation. On examination a fortnight after, he found the upper part of the vessel containing the oil, studded with white, shining, chrystalline scales, bearing a very remarkable analogy to the micaceous chrystals formed when oil of fennel is exposed to a low degree of temperature. These chrystalline scales were less odorous than the oil itself, but their taste was much more burning and permanent—*Buchner, Opere Citato.*

On that Constituent of Opium, which is Insoluble in Cold Water.—It is generally believed by pharmacologists that the virose principles of opium are completely extracted by water; Marlin has, however, discovered that the residue of opium which is insoluble in water, cold or warm, when subjected to fermentation with sugar and yeast, still furnishes a preparation of strong narcotic power. The following is the proximate analysis of the magma which had been left after the preparation of watery extract of opium, and of acetate or muriate of morphia. Brown extractive matter narcotine, fat oil, resin, caoutchouc, bassorine, and another undefined gummy substance, sulphate of lime, and vegetable fibre. A portion of this residuum—insoluble in cold water—was mixed with 175 parts of sugar, and 40 parts of beer yeast mixed with water, and then exposed to a temperature of 25°. When the fermentative process was perfected, the liquid was filtered and evaporated in a water bath to the consistence of a hard extract. This extract was again dissolved in water, and fermented with a fresh addition of sugar and yeast, afterwards filtered, and again evaporated. This fermented extract of opium was brown, of a peculiar aromatic smell and bitter taste, leaving behind a sensation of heat in the mouth. Three grains of this extract administered to a strong muscular man, caused narcotism and head-ache, and a second dose of equal strength as the first, produced vomiting. Sixteen grains of this fermented extract of opium administered to a pretty strong dog, caused death after an interval of some hours.—*Buchner's Repertorium,*

Are Toads Poisonous?—The following strange case affords an affirmative answer to the foregoing question:—A healthy married woman, 30 years old, living near Lomnitz, in Moravia, became affected with bronchocele after parturition. Anxious to get rid of this deformity, she tried in vain several domestic remedies for its relief; at last she was advised to apply a dead toad over the swelling: this immediately caused such violent inflammation in the scrophulous tumour, and in the neighbouring parts, that she was forced to seek medical aid for its removal. Dr. Pluskal, who was consulted on the occasion, found the patient labouring under violent inflammatory fever, accompanied by great anguish and restlessness. Her head was hot and painful, the face swoln and red, and she was unable to articulate; breathing, swallowing, or an attempt to speak, caused great pain the tumour. Erysipelas extended over the anterior part of the neck, and the fluid effusion, the result of the inflammation, was so copious, as to completely conceal the bronchocele. The antiphlogistic plan of treatment was at once adopted, but without success, as the patient died of suffocation on the third night after the application of the loathsome remedy.—*Oesterr. Medic. Wochenschrift.*

On the Effect of Alum in Gastro-Enteritis.—Induced by the great praise with which Papper recommended alum in abdominal typhus, the writer of this paper has used it in two cases with the best results. A young man, 15 years old, was attacked with gastro-enteritis, which soon assumed a typhoid character. The disease, in addition to the usual pathognomonics, was attended with diarrhœa. A drachm of alum dissolved in six ounces of arrow-root mucilage was given by table spoonful every second hour. The diarrhœa was quickly checked; after some time the tongue became moist, the thirst less, the dryness and heat of skin were succeeded by a mild perspiration, and a favourable crisis was established on the fourteenth day. A boy of 13 years of age was also seized with gastro enteritic typhus, complicated with bronchitis and hoarseness. Coolliquative diarrhœa, delirium, and other typhoid symptoms, soon set in. On account of the lesion of the function of innervation under which the patient laboured in this latter case, camphor, valerian, and cinchona, were combined with the alum. The result in this, as in the first, case was highly favourable. The unfavourable symptoms gradually gave way, and were succeeded on the twenty-first day by a critical resolution of the disease.—*Dr. Ritter, of Rottenburg, in Heidelberg Annalen.*

On the Use of Large Doses of Iodide of Potassium in Gastro-Enteritis—As the result of observation of numerous cases of gastro-enteritis treated by large doses of iodide of potassium, the writer lays down the following rules for its administration. In cases attended with foulness or acidity of the stomach, an emetic is to be prescribed previous to the administration of the iodide. When symptoms of acute gastritis are apparent, from twelve to sixteen leeches must be applied over the stomach. These conditions being premised in both cases, the subsequent exhibition of large doses of iodide of potassium produces the happiest effects in cutting short the fever. In cases of pure gastro-enteritis, unattended with any complication, the iodide may be given—and with success—from the commencement of the disease. Administered in cases where the primary gastro-enteric inflammation had run into follicular ulceration, it was equally successful, the symptom of disease vanishing as the remedy was steadily continued. When administered to convalescents from the disease, whose only affection was debility, it invariably proved injurious by increasing the debility and inducing anæmia. In such cases the muriated tincture of iron quickly restored the patient's health. The writer of this paper concludes, that iodide of potassium acts beneficially in gastro-enteritis, by its indirectly antiphlogistic power. Thus, when given for a considerable period, in cases of this disease, which from some complication or other have proved fatal, numerous dissections have verified the assertion, that the gastro-intestinal mucous membrane has been found in an anæmose state, the follicles pale, elongated, and enlarged, but without any sign of redness. If ulcers existed, their margins instead of exhibiting the usual erythema, were soft and pale. When typhoid bronchitis set in as a complication with the gastric fever, the writer invariably had recourse to the use of a decoction of Senega root, combined with iodide of potassium.—*Dr. Rothamel, libro citato.*

On the use of Laurel Water and Sulphate of Quinine in Gastro-Enteritic Fever.—Advantage has been derived from the use of both these remedies, not alone in gastric enteritis, but also in typhoid pneumonia. The former of these remedies is said not only to have cured the above diseases but that it also has the power of cutting short and immediately checking an attack of typhus. For cutting short the progress of gastric enteritis, it is given as follows:

℞ Decocti salep ℥v.
Aquae Lauro-cerasi ʒ ij. fiat mist.

Capiat æger cochleare amplum alternis horis, instanti febris gastro-entericæ paroxysmo frigido.

But this remedy will produce no beneficial effect if the disease be complicated with symptoms of typhoid pneumonia, or low inflammation of any other organ. Laurel-water has been administered all through the progress of these intestinal fevers, up to the approach of the crisis, when decoction of bitter-sweet is substituted for that of salep, as a vehicle for its administration.

When the inflammatory stage has passed away, giving place to nervous debility, the laurel water must be laid aside, and the sulphate of quinine in

doses of 1-6th of a grain administered every second hour. The exhibition of the quinine very soon removes all these unpleasant symptoms, and materially assists the patient's convalescence. When the disease has existed for a considerable time, or is attended with colliquative diarrhœa, the cold infusion of cinchona is far preferable to quinine, and the effect of the former will be considerably increased by combining it with musk in small doses. During the progress of the fever, the writer of this paper adopted Broussais, dietary; allowing his patients only new milk and water, after which at the crisis, elder-flower tea was substituted. From a register kept of the number of patients treated by the writer during the prevalence of two gastro-enteritic epidemics, out of the whole number 210 only 14 died, leaving the recoveries as 14 to 1.—*Dr. Rosevar, in Med. Wochenschrift.*

PROGRESS OF ENGLISH, AMERICAN, AND ITALIAN MEDICAL SCIENCE.

(The following comprise the principal articles of interest in several recent numbers of the *Medical Gazette.*)

OPHTHALMITIS.—Dr. Mackenzie, of Glasgow, in a clinical lecture recently published on ophthalmitis, refers its occurrence to two most prominent causes—injuries of the eye, and the circulation of purulent matter in the blood. The disease, when arising from the former cause, is called *ophthalmitis phlegmonosa*, or *traumatica*, from the latter, *ophthalmitis phlebitica*. Some cases are occasionally met with which appear to be essentially *idiopathic*. It commences with slight external redness, the conjunctiva being the seat of white chemosis; the aqueous humour is muddy, or tinged with blood, and the fundus oculi appears reddish. The iris is changed in colour, the pupil contracted; the lenticular capsule sometimes opaque, in other instances transparent; the pain is severe and pulsatory; it is experienced at the bottom of the eye, and in the orbit, extending to the forehead and temple, and accompanied by a feeling of burning heat, tension, and fulness. There is also much intolerance of light, and a sensation of shining flaming spectra before the eye. As the retina becomes insensible from change of structure, or the pressure of effused pus, this last-named symptom disappears. This state is followed by protrusion and fixedness of the eyeball, from effusion into the cavity of the ocular capsule; it is excessively hard to the touch. When protrusion takes place, the interior of the eye is disorganised, and vision extinct. The conjunctiva continues greatly swollen, and is covered, especially that portion of it which lines the lower eyelid, by a layer of coagulable lymph, which can be peeled off like a membrane, and which forms again by-and-bye. This is met with both in the traumatic and phlebitic ophthalmitis, and serves to shew the analogy existing between these two varieties of the disease. If the lens and its capsule are transparent, the vitreous humour may now be sometimes seen of a grass-green color, the result of pus effused within the hyaloid membrane. The iris advances towards the cornea, and matter is plainly deposited in the posterior and anterior chambers. The whole eye and the ocular capsule being thus full of purulent matter, if life is prolonged, the matter, unless interfered with by art, after immense suffering, makes its way to the surface, and escapes. The bursting of the eye, or of the capsule, is a means of saving the patient's life, against whose recovery the chances are very great if the disease is left to itself, and no spontaneous evacuation of the matter takes place. This is effected either by sloughing of the cornea, by the bursting of the sclerotica into the ocular capsule, and the discharge of the pus through the conjunctiva, or by the latter only, the sclerotica remaining intact. If the eye retains anything of its natural appearance, and especially if there remains any sensibility to light, the eye itself has not burst; the capsule only has given way. The constitutional symptoms are of variable intensity, but generally very severe. The patient is affected with rigors, anxiety, insomnia, delirium, and sometimes convulsions, especially if the case is about to terminate fatally. The pulse is full and throbbing in the commencement; in the later stages of the disease, it is small, weak, and very quick. The disease may terminate in amaurosis, the form of the eye remaining natural, the pupil contracted, the lenticular capsule opaque, and the retina insensible, or in suppuration and rupture of the eye or capsule, or of both; and again, death is not an uncommon termination of ophthalmitis by the supervention of coma. A perfect recovery is very rare indeed. The principal causes are injuries, such as the operations for cataract, not extraction only, but sometimes even division through the cornea or the sclerotica; the excision of staphyloma, injuries received in blasting stone, and the like; in particular states of the constitution, a very slight injury indeed will produce it. [We have seen it caused by a prick from a thorn striking the eye.] Another cause is the circulation of pus through the system, arising from inflammation of a vein, the pus being arrested in one of the minute vessels of the eye, perhaps in the veins of the choroid, and there exciting inflammation, and a new secretion of matter, not a mere deposition of that which was carried in the circulation from the vein originally inflamed. There is reason to believe that ophthalmitis follows as a sequela of fevers, both eruptive and others, such as measles, small-pox, scarlatina, and typhus. The symptoms in both the phlebitic and the traumatic forms have a close resemblance to each other, and the treatment in each at the commencement, requires the free use of the lancet, cupping, and the application of leeches. Dr. Mackenzie also recommends the free exhibition of mercury, and says the only case of ophthalmitis (a very bad one), in which he witnessed a perfect recovery, was one in which he made the mouth speedily sore with calomel and opium. As soon as mercurial action was excited, the ophthalmitis began to subside; the eyeball retreated into the orbit; and a perfect cure took place. He has never tried nauseating doses of tartar emetic, which have been recommended in such cases. Counter-irritation to the feet, such as by mustard baths, or mustard poultices, and counter-irritation to the nape of the neck by blisters, as well as blisters behind the ears, will be proper. Pledgets wrung out of cold water, and frequently changed, are the best local applications in the early period of the disease; afterward a warm poultice. Extract of belladonna may with propriety be smeared on the eyelids and eyebrow. With regard to diet, in the early stage abstinence from food, and water only for drink should be directed; but afterwards, when the patient is weak and exhausted, mild nourishment may be allowed, and quina exhibited. The last point in the treatment consists in making a surgical opening into the eye or the evacuation of the serous fluid and pus, either through the cornea or sclerotica, by doing which, Dr. Mackenzie avers he has in several cases saved the patient's life. The plan of opening the ocular capsule he first employed in February, 1842, on an eye affected with traumatic ophthalmitis, which was excessively hard and greatly protruded, with an obscure sense of fluctuation around it. He divided the conjunctiva in a vertical direction at the inner canthus, and towards the lower eyelid, and then directed the lancet backwards by the side of the eyeball, between it and the lower inner wall of the orbit, so as to avoid the rectus internus and rectus inferior. There was a sudden discharge of serous fluid mixed with pus, and the eyeball immediately sunk back, and the cornea became quite flaccid, showing that the cause of the previous excessive hardness of the eye, and of its protrusion, had not been in the eye, but behind it. This proceeding Dr. Mackenzie recommends for early adoption in all similar cases; not to be delayed until the eye is disorganised, or the patient sinking into the state of coma. It is simple and easy of performance, and affords the most likely means of saving both the vision and the life of the patient.

THE BICYANIDE OF MERCURY.—Dr. Letheby concludes from his experiments that the bicyanide of mercury acts, when put into the stomach of dogs, as a powerful local irritant, occasioning violent vomiting, and subsequent purging, and bloody evacuations! The constitutional effects are first a loss of volition; the animal totters, and loses control over the limbs, as if they were paralysed. The mental faculties, however, are not impaired, nor does there appear at this stage to be either pain or spasm. The second effect is like that of prussic acid,—violent convulsions, loud screams, and a spasm of the respiratory muscles; from this time reflex action ceases, and the subsequent effects are, paralysis of the voluntary, and afterwards of the involuntary muscles coma, the breathing becoming slower and slower, and the heart's action fluttering, and subsequently laboured. It at first appeared that these effects were rather due to a gradual liberation of hydrocyanic acid, which maintained a slow but constant action upon the system; but the fact that the same symptoms are produced when the salt is injected into the veins or peritoneum, leads to the belief that the effects are specifically those of the combined elements. His experiments also show, that prussic acid is liberated from bicyanide of mercury when it mixes with the acid contents of the stomach, and secondly that both it and the mercury are easily detected. When the poison is given in a large dose, its irritant action produces such constant and violent vomiting, that it is all expelled. The *post-mortem* appearances are, a highly congested state of the stomach, a semi-coagulated black blood filling the right side of the heart and cavæ, and a congested state of the vessels of the brain.

PALSY.—Dr. Blackmore, in his observations on the nature and treatment of the more important diseases of the nervous system, states that palsy occurs as a simple and primary affection, even when its origin is within the head; it may terminate favourably, or pass into apoplexy on a more powerful application of the exciting causes, or when it has been treated inefficaciously. Some of its symptoms are peculiarly singular and interesting; such as, the remarkable variations in the state of the pulse, and of the animal temperature of the affected limbs, in connection with an improvement or aggravation of the other symptoms;—spasms of the palsied limbs, without any effect on the palsy—habitual tremors of the limbs, without any loss of feeling or of voluntary power, forming the paralysis agitans of writers—thermometrical coldness of the affected parts, without the sensation of coldness; and the converse; incessant and severe hiccough, which does not seem to affect the course of the disease; the tendency of compressed parts to slough; and various affections of the senses, of touch, hearing, and sight, with sometimes long interruption of the sleep, without mental disorder. Primary palsy, like apoplexy, is sometimes connected with obscure disease of the heart and aorta, and is often the first symptom that rouses the attention of the sufferer to his real state. Palsy, although sometimes connected with a first attack of acute epilepsy, or transient epilepsy with convulsions, seldom arises from chronic epilepsy. Paraplegia, occurring from an affection of the spinal cord, may pass into hemiplegia with brain disease. Chronic cases of weakness of the limbs, appearing to be rheumatic, are sometimes truly paraplegic, and are often mistreated. A sense of girding in the abdominal muscles is sometimes the first symptom in these cases, and should direct attention to the spinal cord. Simple or primary palsy is generally more hopeful than palsy secondary on apoplexy. Recent cases of hemiplegia are hopeful, although the senses of sight and hearing are affected with illusions, and other evidence is present of an extensive affection of the brain. Instances of a recurrent attack, at an interval of some years, even where the speech has been affected, may end in recovery. Hemiplegia, however, when connected with disease in the heart, is hopeless. Incomplete paraplegia with neuralgia of the lower extremities, even when of two years continuance, is hopeful, when the encephalic and vital functions are unbroken. In paralysis agitans of one year's continuance, complete recovery is not to be expected; but it may admit of great relief. Sloughing of any part subjected to pressure is a bad sign, particularly that painful sloughing of the ball of the great toe; the vital powers then quickly sink.

There is more hope of palsy secondary or acute epilepsy with transient coma, than of that following decided apoplexy; and it admits of hope, even although the epilepsy has been recurrent and severe, and after disease in other organs; but if proper remedies have been neglected in the first fortnight of the attack, partial palsy may be expected to remain, and generally hemiplegia following epilepsy is of bad omen. The causes of palsy are either encephalic, spinal, or local. In the first of these the true cause seems to be pressure on the figurate brain—or the corpora striata, crura cerebri and cerebelli, medulla oblongata, tuber annulare, and the origin of the various nerves of motion and sensation. It may be produced and maintained by congestion only, or its persistance may be caused by a lesion or congestion of the medullary substance. Partial palsy may have an encephalic origin, and may pass into apoplexy. Hemiplegia probably has (not) always an encephalic origin; but mere partial palsy, whether of a single muscle, or of the abdominal muscles, and pelvic viscera, or of the legs and arms, may have its origin in the several horizontal segments of the cord. Palsy may also arise from disease in the nerves external to the brain and spinal cord. The treatment of the acute state of encephalic palsy will be the same as for apoplexy, a consequent attack of which may be thus prevented. Dr. Blackmore seems to be of opinion, that the use of mercury is very important in such cases. When the palsy is derived from disease of the spinal cord, cupping and free purgatives are strongly recommended by the Doctor. He says that so great is the torpor of the bowels, and so vast the accumulation of fœces, that the practitioner scarcely knows when the bowels are really unloaded. The treatment in the chronic state must be regulated according to circumstances, and the symptoms which present themselves.

Disease of the sternum.—Mr. Stafford mentions the case of a man with a diseased state of the lung, who suffered from pain in the situation of the sternum, followed by abscesses and ulcerations, at the bottom of which the bone and cartilage could be readily felt with a probe. The local treatment consisted in the use of iodine, and bark, and quinine, with generous diet were used for the support of the system. Under this plan the ulcers healed, and the chest disease became quiescent.

Sulphate of Manganese.—Dr. Goolden has tried this remedy in several cases, and has found it, when taken upon an empty stomach, in the dose of one or two drachms, act invariably as an emetic. When taken after a meal its emetic action was not so constantly produced, and a tolerance of that action is generally experienced after the first dose. It very rarely acted as a purgative. The appetite has invariably increased during its exhibition, and when the first emetic effect has subsided, the patient is free from all uneasy sensations, and expresses himself as feeling lighter and easier than before. The stools, which are sometimes dark-coloured, soon become yellow and loaded with healthy bile; but if its use be continued for a few days, they become lighter, and at length shew a total absence of bile, appearing like jaundiced stools, of the colour of parchment, but there is no jaundice either in the skin or urine. If the medicine be discontinued, the yellow colour of the stools returns.

Pericarditis a sequela of scarlatina.—Dr. Scott Alison has published several cases to shew that pericarditis occasionally occurs as a sequence of scarlet fever, and he quotes several authors in confirmation of his opinion. He considers, that the inflammatory affection of the pericardium may owe its origin to two different sources, viz., the presence of the specific poison in the blood, acting as a local irritant, and extending throughout all the membranes and tissues of the body, and the presence of crystallizable compounds in the blood, which should have been eliminated from the system by means of the kidneys, but which in consequence of disease of those emunctories are not unfrequently retained in the circulation.

Cyanide of silver.—Dr. Letheby from the results of several experiments instituted by him, concludes that the cyanide of silver acts as a local irritant, producing great vomiting, and a congested state of the vessels of the stomach; that when it has been dried before its introduction into the system no other ill effects follow, but if it is administered in a moist state, it is then capable of becoming absorbed, and perhaps decomposed, for an albuminous solution has the property of dissolving the cyanide, and moreover its contact with any of the chlorides of the systemic fluids would produce a double decomposition, and the formation of a soluble cyanide whose effects would be similar to that of the cyanide of potassium. The specific action of the cyanide of silver seems to be on the brain, producing occasionally convulsions, always coma, paralysis, a peculiar sighing respiration, a fluttering, irregular, and tumultuous action of the heart, and it ultimately kills by a gradual exhaustion of the involuntary powers, death taking place in from one to three hours after its administration. The *post-mortem* appearances are a dilated pupil; an injected state of the vessels of the brain; the heart gorged and full of black blood, especially on its right side; and, when the poison has been administered by the stomach, that organ is exceedingly congested, completely emptied of solid matters, and may smell slightly of prussic acid. There is no difficulty in detecting chemically the presence of both cyanogen and silver.

NOTICES TO CORRESPONDENTS.

We had intended to have given, on this week, eight extra pages, containing the Index and Title-page to our last volume; but unavoidable circumstances have forced on us a postponement until the next number.

X. Y.—*The law allows, and has done so for years past, surgeons and apothecaries to charge for their medicines and visits. In this respect, the Bill is no improvement.*

M.D. and a Constant Reader *will be able to register as a physician.*

Justitia.—*A Scotch physician, by the New Bill, will be able to register as a physician, and practice in the way he likes, just as now.*

A Medical Reformer *labours under a mistake about the divisions in the Profession, formed against the Bill. No one in England is opposed to reciprocity of practice through all parts of the kingdom, and Scotch and Irish graduates have just as strong an interest against being inundated by young two-years' men, as have the medical men of England.*

An Irishman *sends us an eloquent philippic against the Bill, enlarging on the knowledge of medical matters possessed by its framer, who was positively ignorant that Ireland had its Apothecaries' Company as well as England. It is the old story of the tragedy—Hamlet, omitted by special desire. The Irish apothecaries are the largest body of medical men in Ireland.*

Papers by Dr. Clay, "On Various Debatable Points in the Principles and Practice of Midwifery;" by Dr. Costello, "On Lithotrity and Lithotomy;" by Dr. Jobert de Lamballe, Surgeon to Louis Philippe, "On Autopsy;" by Dr. Hodgkin, "On the Syrian Medical Aid Institution;" by Henry Browne, Esq., M.B., Assistant-Physician to King's College Hospital, "On Rupture of the Heart;" by Dr. Sutro, "On Scrofula;" by G. B. Childs, Esq., Surgeon to the City Police Force, "On a New Description of Instrument for Tying Hæmorrhoids;" by M. D. "On the Double Qualification;" by G. Sayle, Esq., M.R.C.S.E., "on Paralysis;" by Dr. Clarke, of Plymouth on "Poisonous Fish;" by Lucius, "On Medical Reform;" have been received, and will be inserted as soon as possible. Numerous other correspondents, whose communications are not mentioned in the above list, must consider them as gratefully declined.

Medicus—1. *Could register under the New Bill as physician.* 2. *No fees would be paid, except the one named in the Bill, viz. one pound.* Medicus *may await, without fear, and in quiet, the turn of events.*

M.D. and a Subscriber.—*The jury will always fix what is a reasonable charge for attendance and visits, under the present law, to all but physicians, who cannot sue for their fees, except under a special agreement. Under the New Bill, the right to sue is confined to* "licentiates;" *physicians and surgeons are left by it without any remedy against a fraudulent debtor.*

Palmam qui Meruit Ferat *sends us a clever letter, but it is somewhat free, and is besides* anonymous. *We may yet turn it to account.*

M. R. C. S. *proposes, that if surgeons "are to be displaced for the benefit of the 'pures,'" a brazen monument be erected to Sir James Graham from the now useless brass plates.*

A Young Student *will do well to advise with his lecturers, who know the special circumstances of his case. A full answer from us would occupy a column, and then perhaps not be complete.*

A Subscriber.—*We no more see the judiciousness of the practice named to us than our correspondent. It must have an* empirical *origin. Could we have a perfect impression, in wax, of the* seal *affixed to our correspondent's note?*

A Handsome Portfolio *for holding the* "Medical Times,"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 5s.—An allowance is made to the trade.*

Books received.—Douglas Jerrold's Shilling Magazine, Cruikshank's Table Book, Punch Office, Fleet Street; Illuminated Magazine, 111, Fleet Street; The Northern Journal of Medicine, Edinburgh; The London and Edinburgh Monthly Journal of Medical Science, Edinburgh; The British and Foreign Quarterly Medical Review, J. Churchill; The Zoist, Bailliere, 219, Regent Street; The Pharmaceutical Journal, edited by Jacob Bell; The Veterinary Record, Longman and Co., Paternoster Row.

The communication of our Parisian Correspondent, Dr. G. de Beaumont, from the many demands on our space, has been unavoidably postponed this week.

Mr. Close's paper will appear in our next number.

THE MEDICAL TIMES.

Saturday, April 5th, 1845.

Eheu! Quam temere in nosmet legem sancimus iniquam!

The scientific and moral character of the Profession, it is needless to say, is of indescribable importance to the public. The repository of the secret confidence, the hope of the afflicted, the mediator between death and many an anxious family, the medical attendant should, in every case, possess, by education, all the resources science yet has reclaimed for the human race, and, by training and habit, all the high qualities which can give that skill its fullest range of usefulness. Compose a profession generally of such men and society receives one of the greatest blessings man can give her. The only ample atonement which civilization can make us for her physical evils, its greater or less proportion forms the measure, if not of a nation's enlightenment, at least of its good government. There can be no good laws where the Profession is not perfect in the ratio of a country's general progression. As (after the common means of subsistence) it is the people's highest interest, so should it be a state's greatest concern. The aggregate wisdom of the country should supply the people with a skilled and high minded profession, with the same care with which it marshals for them a disciplined and invincible army.

It is something to say of the horrible corporate anarchies, which for years past have made up, in their *tout ensemble*, what has been called the government of the Medical Profession, that though that science and honour, in which the public have so high an interest, depended almost wholly on the sordid and conflicting interests of all sorts of jobbing committees and councils—an irresponsible *commissariat* department ruling, as commander in chief, the whole medical army!—it is something yet, we say, to be able to affirm that the tendency of the Profession, like that of the *plumule* of the *legumen* in the well known experiment of the

botanist, has, despite all obstacles, however ingeniously applied, unceasingly shot upwards. With every sort of pecuniary interest against extended curricula and higher examinations, colleges and universities were so acted on by the circumstances of the time, and the pressure of events, that their demands, in many cases, rose in a remote proportion with the progress of society, and, supported by the zealous labours of those whom no corporate misrule could trammel into inaction, the whole profession ascended. If we are not all we should be, we are at all events far more than charters or statutes would have made us. Whatever our elevation, we have the proud boast that what is worthy in it is *ours*, what is unworthy in it is the *Government's!*

Thus *has* it been. But we are arrived at happier times. One of the first statesmen of the nation has undertaken to place our profession on its true footing. He is all potent, and will touch but to make perfect. Well? The very first proposal that meets our observation, is one to give the country for the future a semi-educated race of medical men! Amid all the competition of rival bodies of examiners, each struggling to catch most candidates, all had at length concurred that medical men should not, on an average, have passed less than four years in preparatory studies. Sir James Graham forms an humbler opinion of the *rôle* of a medical man; thinks far more lightly of his responsibility; and having no pecuniary interest to mislead him, deliberately, in cold blood, and in full possession of his senses, insists that *two years* study shall suffice to make a doctor! And this is statesmanship! This is understanding the wants of the state and the circumstances of the profession! If Sir James be right, how marvellously blind were the Colleges who, to the damage of their own interests, asked so much more? If Sir James be right, what a dearth of medical men should there be compared with the public wants? If Sir James be right, how difficult to tempt candidates into the profession! If Sir James be right, how unnecessarily high must be the quality of the present medical attendance of England!

When the former scheme of Sir James Graham was before us we viewed it with some favour, because we imagined that the uniformity of education it was to introduce would have been a uniformity of a very high standard. The uniformity we have still here—but unfortunately the nature of the standard is not again left to conjecture. The great body of General Practitioners will for the future have a course of study—uniformly two years long!

And this leads us to a very important enquiry. Does Sir James Graham know one word of the effect of his own bill? Has it ever struck him that he is a mere blind cat's-paw in the hands of some wily medical corporators? Does it occur to him, that after all his bill may resolve itself into nothing but a corporate move to raise the wind? Let us just see. Two years study (no preliminary education asked!) is just five years less time than makes a tailor, shoe-maker, or carpenter. There is thus secured a full compliment of medical candidates, and as the expenditure of five years support is in their pocket, they are not ill supplied with funds. They register as students: fees. They attend lectures: fees. They become inceptors; fees. They are examined by the physicians: fees. By the surgeons: fees. By the assisting apothecaries: fees. They register with the Council of Health: fees. Not satisfied with their licentiateship, they again go to the surgeons for a fellowship: again, fees! They transmigrate to another section of the country: fees again. And there is this remarkable circumstance about the fees given, at all times and for all kinds of reasons, that they go into the same pocket. Brodie will register the student: fees! Brodie will give his lectures: fees! Brodie will examine him as licentiate: fees! Brodie will register him as licentiate: fees! Brodie will examine him as fellow or surgeon: fees! Brodie will register him as surgeon or fellow: fees! In the lecture room, in the examining room, in the registering room, at school, college, and Council of Health—Brodie! Brodie!! Brodie!!! Was anything ever more ingenious? The Bill a huge fee trap! Graham unconsciously laying fee springes for his Mephistophiles of a Corporator!

And now, before concluding, let us say one word to our brethren in solemn warning against any tampering with the bill now before the House. Its first great wrong is, that it sanctions, confirms, and amplifies, the infamously unjust Charter granted to the College of Surgeons. This crying injustice must not be allowed to sleep. The evil-doers hope to temporise us into quiet, if not into acquiescence, and to live on till hostility merge into apathy. Let them be disappointed. Let every petition proclaim to Parliament that every reform that reforms not this is a "mockery, a delusion, and a snare." The National Association would not do ill to circulate one form of petition throughout the whole profession, and, collecting together some eight or ten thousand signatures, transfer it to Mr. Hawes or Mr. Wyse for presentation. It would produce a remarkable effect. No Government would think of resisting its prayer; for no government could administer a medical law morally and legally resisted by so large a body of Practitioners. There could be no such thing as registration with such an opposition, and the Association at the head of the profession would be entitled to say—"Give us the organization *required*, not by the interests of corporations, but of the profession, or we constitute ourselves into a National College of Physicians and Surgeons, with the most eminent men in the kingdom for our examiners!" The threat would not have to be repeated. So serious a disruption from the legal institutions of the country—parallelled only by the Scottish Free Church secession—would ruin any minister who caused it!

"Observavi enim multos spirituum copia haud satis uberi præditos, ac insuper cephalalgiæ, vertigini, palpitationi cordis, artuum tremori, aut stupori obnoxios, a potu theæ illico deterius habuisse quoad istos affectus, et statim in toto corpore languorem insolitum persensisse."—Willis.

"Hic homines tam brevem vitam colunt—
Qui herbas hujusmodi in alvum suam congerunt
Formidolosum dictu, non esu modo,
Quas herbas pecudes non edunt, homines edunt." —Plautus.

We do not altogether agree with the words of our friend, Plautus, and thereby insinuate, that because four-footed animals would refuse tea, we should do likewise. For, as most philosophers say, and ourselves being philosophical, we say also, there is not a very intimate relation or resemblance between the habits and appetites of quadrupeds, and the intellectual of the biped class. Plato might have been, for aught we know, pretty near the mark, when he called man *a two-legged animal without feathers*, and yet there seems to have been something of practical, and most silencing satire in the feat of that waggish old fellow-philosopher, who, having plucked a cock bare, turned him into the groves of Academus, and called him *one of Plato's men.* We know no more of the *animus*, than of the *anima, galli*—no more of the *mind*, than of the *vital principle*, of a cock; and are therefore not prepared to say whether the position which this gallant bird holds in the great system of *metempsychosis*, would be affected by his going without his feathers, any more than by wearing them. Pythagoras says nothing about it, and even Æsculapius, who was a great *cock-fancier*—we desire that this phrase may not be confounded with the modern unclassical one, *cock-fighter*—has left no memoranda on the subject. We are, consequently, in the dark, as regards this department of mental and moral philosophy. Nevertheless, we dare affirm that, if every feather plucked from this said bird brought him nearer to humanity, he would lose his very skin before he became a tea-drinker. Crassus is said to have laughed only once in his life, and it was upon the occasion of seeing an ass eat thistles. To us, there seems nothing, either marvellous, or mirthful, in the performance, and we are inclined to think that, if Crassus had seen a game-cock drink tea, he would have laughed himself to death. And no wonder, especially if he were a physiologist, for who would not laugh to see an animal's appetite at utter war with its nature. The bird we are speaking of, is a gallant bird, as we have said, and is as remarkable for his fidelity to the feminine part of his tribe, as for his pugnacity towards the masculine species. He is, in fact, a most constant lover—an Orpheus, to whom every *cantrix* is an Euridyce—saying or singing to each of his many mistresses.

Te dulcis conjux, te solo in littore mecum,
Te veniente die, te discedente canebam.

With such a constitution, and amorous appetite, what could possibly induce this bird to drink tea? It is well known that he prides himself upon the depth of hue, and brilliancy, of his plumes, and carries his prodigal person with an unusual dignity of stride, after having viewed himself from side to side, in the feathery looking-glass of his own frame. The sticklebacks recognise, as their leader, the most brilliantly, and deeply, coloured of their shoal—his hue is his authority, his pigment his protection—and none other fish of his company will contend with him. So, on the other hand, one game cock, in less gaudy attire than another, will not meet, with confidence, his more showy antagonist, and meeting him, is pretty sure to be vanquished. Even the hens will as certainly run after the best-dressed and brightest-eyed male of the same species, as they will take any one of the latter in preference to a "dunghill." We do not mean to say that game-cocks are classical scholars, and can give, as their reasons of conduct, the texts of antiquity, but we unhesitatingly aver that what Martial stated as the result of hearsay, or observation, they stand by, as a rule of instinct. Try these said birds with hot tea, and see if they will drink it! Take our word for it they will not. And who shall say that the "*vis medicatrix naturæ*" within them, does not whisper, "it will spoil your complexion?" We must admit that the fear of growing pale, either arises from this inward monitor, call it appetite, or what you will, or from an intimacy with that striking passage in Martial—

Et potet calidam, qui mihi livet, aquam.

But there is another reason why we think this bird could not be persuaded to partake of the "fragrant herb". We have already alluded to his propensities—he may not be acquainted with the following passage of old Willis, but it is impossible to say that instinct does not serve him

in this warning's stead. "Ita quidem rem habere, tantum ratio, sed et vulgaris observatio passim dictitat; in quantum *thee* potatores nimii, macilenti, sæpenumero item paralysi, atque veneris impotentiæ obnoxii, evadunt. Prior effectus ita frequens et passim notus est, ut pluribus *thee* potum ideo tantum interdixerim, quoniam ad macilentiam disponit." Understand, reader, that in this joke concerning the sacred bird of Æsculapius, we have only been anxious about expressing modestly, an important matter of fact. So much for the *relation of difference* between man and the inferior animals, as regards tea-drinking—now for the *relation of resemblance* on the self-same subject. The resemblance, be it understood, refers to quantity rather than quality of drinking though there is no reason why we should hold exclusively to the one side, for if a tea-infusion be nothing better than "hay-water," as the Dutch writer called it, we see no rule why it should not be "nectar," as well for horses and asses, as for men. Waiving this, however, we proceed to show how the intellectual bipeds often rival the most capacious quadrupeds in the amount of fluid which they swallow. At the bottom of this mysterious performance lies tea—and like the bottom of Diogenes' tub, be assured, worthy reader, that this said tea is not wholly exempt from blame. Marvellous tales are told of the capacity of human appetite and organs for fluids. It is said that there was exhibited at Strasburg, the stomach of a hussar who could drink sixty quarts of wine in an hour. Piso—Seneca and Tacitus vouch it for a fact—could drink for two days and nights incessantly. Pliny says that Novellus Torquatus drank three *congii* of wine in the presence of Tiberius; "and Rhodiginius mentions a capacious monster down whose throat an *amphora* of liquor could be poured without interruption." We are not in the humour for believing any of these statements: did we believe them we should certainly say—

"The power of nature could not further go."

As matters stand, without any disrespect to Gulliver, *et hoc omne genus*, we must pay the same compliment to the power of fiction. Though we have never seen tea-drinking reach anything like the height just mentioned, yet have we known it to go to some extraordinary lengths. We have not, like old Weller, observed a tea-tippler to "swell wisibly afore our werry eyes," but we have seen as much tea swallowed at one sitting as ought to have produced that astounding effect: whither it has gone has often puzzled us. For, as a witty Irish friend of ours once said, it does not always happen under these circumstances that we meet with the geographical anomaly of the *Tay* and the *Po* joining one another. De Quincey says in his "*Confessions*,"—"I usually drink tea from eight o'clock at night to four o'clock in the morning"; now if he were only to swallow with tolerable celerity during that space of time, I think he would go a step beyond anything we have ever seen in this said line of performance. But De Quincey is a scholar and a philosopher, and pauses over his "cups" to read and think; the time, therefore, which he occupies in imbibition, is no measure of the quantity of material consumed. To see a real feat of deglutition, you must take the tea-drinker *con amore*, the man who loves the decoction for its own sake, not for any reading or conversation to which it may help him; who cannot stop to answer any question you may put to him, and whilst pretending to be engaged in thought, is only wishing his gullet were a mile long, that the pleasure of swallowing might be increased in proportion. That is the man whom we introduce as a specimen of a real tea-drinker, the only man, in fact, who can drink *usque ad nauseam, repletionem, vel ruptionem*, as the case may be. In the Philosophical Transactions is related the fact that, a woman who had an inordinate love of distending her stomach, was in the habit of gratifying her desire by putting the nozzle of a bellows down her throat and blowing away until she was tired. Ludicrous as this appears, it is scarcely more so than many examples of inordinate tea-drinking that we know of. No wonder that the practice should have engendered morbid fancies, and been the frequent occasion of night-mare. It was the source of the phantasy which possessed Franklin, when he thought himself converted into a tea canister, and was perpetually being handled, opened, and employed in trifling merchandise. Another philosopher, for the same reason, fancied himself transformed into a tea-pot, and was twice a day harassed and agonized by being brought to the meal table and scalded with boiling water. We knew a student who was a monstrous tea-drinker. It could not be said of him as Dominie Sampson said of himself "thou exceedest not in potations"—for he was always drinking. If Œschylus could never compose except when in a state of intoxication, so could this man never study except when glutted with his favourite beverage. If he came to your rooms, he was as certain as a wet nurse or a washerwoman to make an attack upon your tea-caddy, and if you visited him, his everlasting kettle was singing a constant invitation for you to scald or choke yourself. Like a Dutchman, he invited all comers with a pail and a dish, and like some of the Orientals by their salt, it might be said of his tea, "qui potare recusat, hostis habetur." But that his society was worth having at any cost, no man would have been bored with his interminable drink. We often tried to reason him out of his habit, but in vain: he was as thirsty as Tantalus, but unlike him, was never the martyr of disappointment. A dream however laid wait for him, and cured him of a folly which had defied all the advice and entreaty of his friends. One night, after having unusually replenished himself, he retired to bed, but instead of going to sleep, he was seized with "thick coming fancies" which variously troubled him. Shortly, he became insensible of everything around and about him, except the figure of a tea-pot, which, slowly emerging from the bed-clothes, was seating itself upon his stomach. It was no common tea-pot—it was an eternal one—like De Quincey's, eternal "*a parte ante et a parte post*"—it threatened to smother him with its magnitude, and he was certain it must be full, for its weight was like to crush him. He dared not attempt to stir, lest he should be overwhelmed with the contents; and to remain under the load was to run the risk of suffocation. All this was horrible enough, but judge of the increase of torture when this tea-pot became like a living thing, and staring at him with eyes that leered in their cruelty, told him he must drink it dry. He felt that his stomach was already full, and were it possible for it to contain any more, he had not the appetite or the ability to swallow. Nausea seized him, but he could not vomit, and whilst thus agonized, the inexorable tea-pot demanded to be emptied. He tried to implore it, but could neither speak nor make a sign—the tea-pot moved as if an unseen hand were preparing to pour the fluid down his throat—his mouth was already open, and in vain he tried to close his lips, the vessel approached nearer and nearer, and a suffocating gush at last awoke him to a consciousness that an imaginary incubus had been the cause of his oppression. His nausea returned with more success than before, and, after having unloaded his stomach, left him more quiet and composed. The idea haunted him through the night, but less terribly than at first, and the sight, of his breakfast-table on the following morning, renewed in some measure his horrible vision. For weeks afterwards he could not endure to look upon a tea-pot, and never again became thoroughly reconciled to his old beverage.

THE PROFESSIONAL MOVEMENT.

The Dorchester Medical Association has distributed circulars to all the Dorsetshire Members of Parliament, stating briefly their objections to the Bill. They say of the Council of Health: "six physicians—five pure surgeons—seven Government nominees—no representative of the General Practitioners!" They complain of the effect of one *subordinate examination*, instead of two respectable examinations; of two years' study, instead of from five to seven; of the Council of Health's *power* over public institutions—and the semi-license granted to empiricism. The document is forcibly drawn up and should be widely distributed.—A meeting was held also at Belfast on the 17th instant. Much misconception seemed to prevail as to the tendency of the Bill; a physician, Dr. S. S. Thompson, considering the Bill perfect, and other gentlemen finding in it considerable matter for objection. Resolutions were ultimately adopted, partially approving and partially condemning the measure. The Bill's great tendency to lower qualifications was distinctly proclaimed and incorporated into a resolution.—Mr. Richard Quain, F.R.S., Surgeon to the University College Hospital has written a clever pamphlet, exhibiting in the strongest light the mischievous effects of the Bill in depreciating medical education. He particularly enlarges on the power the Bill gives to the College of Surgeons of Edinburgh (a body of General Practitioners and not more numerous than the staff supplied by a single London Hospital) of supplying Surgeons (Fellows) and General Practitioners (Licentiates) to the whole empire! The pamphlet should be read by all who would form an accurate notion of the educational deficiencies of the Government measure.—Mr. Dermott, the eminent anatomical teacher, has also published an unsparing critique on the Bill, in which he lays bare clause by clause the parts, which to his vision, appear palpable agencies to raise corporate *cliques* and depress individual practitioners.—The Manchester branch of the National Association has published a vigorous manifesto. To the College of Surgeons they speak the language of dignified rebuke. They reject with scorn the insulting proposal of gaining the Fellowship by additional purchase, and pledge themselves to unceasing hostility to the recent innovations. To Sir J. Graham they denounce the College Council for its presumption in designating itself *the* College in its petition for the New Charter—explain the wrongs that document has causelessly and uselessly inflicted—and call for a supplementary Charter. A petition is added by them to the House of Commons, protesting in energetic terms against the Bill, as sanctioning a Charter so justly odious to the whole Profession.—On the 18th inst a meeting was held of the Hertfordshire Medical Association, in which some very judicious resolutions were passed, strongly protesting against the maintenance of the Charter, and pointing out certain portions of the Bill which more or less license empiricism, and do injustice to the General Practitioner. A number of documents and reports are before us, which we shall notice in our next number.

RETIREMENT OF SIR BENJAMIN BRODIE.

There is a rumour current, and very generally believed, that Sir Benjamin Brodie will almost immediately resign his Corporate connection with

the Royal College of Surgeons. He can adopt no more prudent course. If imitated by a nameless Coroner, at the other extremity of respectability, but equally unfortunate in his management of Medical Politics—we shall not be surprised. The first is a *prudent* step, and no reader of the *Medical Times* can fail to observe that the second is not less necessary.

POISONED CREWS AND THE LAW OF LIBEL.

The *Times* journal has been recently mulcted in damages to the amount of £500, for inserting what has been called a libel on Mr. Salomons, a St. Helena merchant. Two statements appeared in that journal declaring that the crew and passengers of a ship named "the Moffatt," had suffered in health in consequence of some impure state of the water, taken in at St. Helena, under Mr. Salomons' superintendence. Very voluminous evidence was gone into, a careful medico-legal examination of which satisfies us that the passengers and crew did really suffer every symptom of a metallic poisoning, while it raises a presumption not of the weakest kind, that the water or some article of not more uncommon use, was in fault. It seemed clear however, that the letters which ascribed the poisoning to copper, mistook the nature of the case, the symptoms described by the witnesses on both sides appearing to us to be the very common ones always following poisoning from salts of lead. We can in no way understand how the Lord Chief Justice could imagine, or feel himself justified in stating, that the symptoms depicted by the witnesses could have arisen from the exhibition of mercury in the ordinary course of medical treatment. Still less can we understand how a jury, without any conclusive evidence that the precise water shipped at St. Helena, on analysis contained no poison, could have brought in as they did a verdict of £500 damages. There is no article in domestic use which through a culpable and often mercenary negligence, is more frequently or dangerously adulterated than water, especially in warm climates, and the *Times* deserves thanks for calling attention to a matter upon which health and life are considerably more dependent than is usually imagined.

MEETING OF THE CITY OF LONDON ASSOCIATION OF GENERAL PRACTITIONERS.

A meeting of General Practitioners of the City of London, convened according to advertisement, "for special purposes," was held on Tuesday evening, April 1st, at Radley's Hotel, Blackfriar's-road. There could not have been less than 80 persons present. The chair was taken at eight, p.m., by John Sim Smith, Esq., and Wm. Smith, Esq., filled the office of secretary.

The proceedings were marked throughout by an exhibition of gentlemanly feeling highly creditable to the meeting, and a calm and patient hearing was given to the statements of some who came there expressly for the purpose of raising objections to the matters to be discussed, and who, had they any ulterior motive in view, must have felt completely foiled at the absence of all opportunity to carry them out. By the patient, and to all appearance, rather contemptuous hearing given to those inimical to the purposes of the meeting; all hope of exciting discord among its members was taken away, and they whose living is procured by "fishing in troubled waters" were for once compelled to abandon their old habits.

The business of the evening was commenced by the Chairman stating the purposes for which the meeting had been convened, namely, to receive a report of the Association relative to the new Bill, which still contained some of its most objectionable clauses; and to consider the conduct of the National Association Committee, which, he as a member of that committee, could honestly affirm, had nothing but the best interests of the profession at heart.

The report was then read, of which the following is a condensed copy:—It stated that since the last meeting, the committee had waited upon the four members for London, who had promised to consider the nature of Sir James Graham's Bill. That out of the number of the General Practitioners practising in London, amounting to about 111, no fewer than 104 had joined the Association, and contributed the sum of £102. 18s. 6d., of which £77. 14s. had been paid to the treasurers of the National Association. After alluding to the objectionable clauses in the new Bill, the Report concluded by expressing regret at the dissatisfaction which existed among a very small minority of the profession, and trusting that unanimity would prevail.

On the motion of Mr. Duplex, seconded by Mr. Herring, the Report was adopted.

Dr. Sewell proposed the 2nd resolution, recognising the benefits conferred on the profession by the new Medical Bill, but condemning it for the defects in the registration principle, the inadequacy of power granted to enforce the penal clause, and the unconstitutional power vested in the Council of Health, and its exclusion of the General practitioners.

Mr. Bullin felt very great pleasure in seconding the resolution. He believed that Sir James Graham could not have carried his measure, and allowed it to exist for two years before it would be repealed. The benefit said to be conferred upon the Universities are in another portion of the Bill taken away. If they consented to such a Bill, they would be parties to their own degradation, for which by the Bill they were obliged to pay. Contrasting the proposed Medical Bill, with the Police and other Bills, he saw nothing in it but an attempt to carry out what was done in them, namely, centralisation. He considered the Bill but as the attempt of some cozening knave to raise himself to honour by the degradation of the Medical Profession.

Put and carried.

Mr. Sparke begged to move the third resolution —That this Association concurs in the censure uniformly bestowed on the conduct of the Council of the College of Surgeons; and acknowledges with satisfaction the honourable contrast afforded by the conduct of the Apothecaries' Society; and hopes that their efforts to maintain the station and character of the General Practitioner, will be effectual in promoting harmony among the whole class of General Practitioners. Before he sat down, he would trespass upon their attention to say a few words. Perhaps that resolution was put into his hands as the oldest member of the profession in the room, and therefore it became him to speak of it with delicacy. Self-interest being the moving spring of all human actions, the support given to the Bill by the different conflicting parties, was given with a view to this great principle of our nature. He considered the present Bill as a new means to carry out the indignity offered to the Profession by the College Charter.

Mr. Mann, in rising to propose the fourth resolution, would, ere he did so, make a few observations to the meeting. A practice prevailed in the police-courts of China, and a very extraordinary practice it was—when a criminal was condemned to suffer punishment for any offence, the punishment was sure to be inflicted—but the unfortunate culprit, after experiencing the tender mercies of the law, was obliged again to appear in court, prostrate himself before, and return his thanks to, the mandarin who had ordered him to be punished. (Laughter and cheers.) Now, on referring to many of our periodicals, and to a portion of the press, he found a somewhat similar custom prevailing at home. These papers and periodicals contained resolutions complimentary to Sir James Graham. (Hear, hear.) On what ground did they offer him thanks? On no other, that he could see, than that in his new, and, as it had been called, amended bill, he had preserved the most obnoxious clauses of his first obnoxious measure. In his opinion, the aim of both Charter and Bill were one and the same—the degradation of the medical profession. He had joined that profession in early life, when his hopes were more sanguine than at present. He had become a member of it, not with any hope of prospective emolument to be gained by doing so. To be sure, he might have been tempted by the museum or the library, or the advantages they held out. No: he was tempted by something higher and nobler; he was tempted to enrol himself a member of that college which reckons among its members so many men of genius; and he would ask the gentlemen around him—was it no degradation to be deprived of that status in the profession which placed them as equals, at least, in collegiate station, with Sir Astley Cooper, that sun of the surgical firmament? (Cheers.) Was it not notorious, that in the College of Surgeons, men were elevated over the heads of the profession who were totally unknown to science? Was it not but fair to expect that such men, appointed Fellows, should be remarkable for superiority in some walk of science? The whole range of English history furnished no more atrocious invasion of vested rights than that about to be perpetrated by the new bill. Were the medical profession a bustling, forward body in public life, instead of shrinking, as they really do, from anything like public observation, or were their interests properly represented in Parliament, no minister dare attempt such an injustice. (Cheers.) To remedy this injustice, two means of redress had been suggested. The first was an appeal to Parliament, and the second an appeal to the College of Surgeons. The college, in justice, should either refund the fees which the general practitioners have paid for their license as members, or else allow the members, on paying the Fellowship fee, to become Fellows. The next means of redress which had been proposed, was the establishment of a new medical incorporation. To this it had been objected, that a long time must elapse before such new incorporation could acquire stability, or a proper recognition of its position in the scientific world; that if, an infant institution, would have but slight chance of victory in struggling with scientific corporations already arrived at all the strength of manhood. The persons who made these objections forgot the adage, "Rome was not built in a day;" and seemed to be quite unmindful of the fact, that the corporations, of whose growth to manhood they had so vauntingly spoken, were once in a state of infantile helplessness. He must confess that some of those corporations had, indeed, attained the period of manhood, and he was certain that one of them, at least, the College of Surgeons, had passed its grand climacteric, and was fast hastening to imbecile and sickly old age. Passing by the trifling objections which had been urged against a new incorporation, he would ask if they had not well grounded hope for the ultimate establishment (if necessary) of such an institution, when each succeeding year revealed the important fact, that the expenditure of the College of Surgeons was considerably beyond its income? How could such a state of affairs end, but in the speedy and total ruin of that corporation? In such a case as theirs, numbering so many supporters, it was impossible but that there should exist among them some trifling discrepancies of opinion. Let these discrepancies of opinion be reconciled, if possible. He considered it possible that uniformity of action might exist among them all, without being at all interrupted by a want of uniformity of opinion on trifling matters of detail. A reference to the history of the past would show them how an assertion, so apparently paradoxical, as that "uniformity of action could be made to harmonize with contrariety of opinion," could be proved true. On the present occasion they could not act more wisely than to take a lesson in policy from the Court of Rome, that court which carried out into action the greatest and boldest scheme of policy that ever entered into the head of a diplomatist. He referred to the Crusades. Now, what was the policy of the Roman pontiff on that occasion? Well he knew the jarring elements of which society was then composed; no one was better acquainted with the wild spirit of feudal hatred which rival barons entertained toward each other for centuries—hatred sent down from sire to son, as an hereditary endowment—and for the gratification of which every consideration, divine

and human, was frequently outraged and held at nought. The reconciliation of these terrible rivals, which, to any one of less subtle imagination, would appear a hopeless task, was, by the spiritual monarch of Christendom, accomplished by a masterly display of wisdom. Under pain of excommunication, he forbade *any person* bearing the holy sign of man's redemption, engaging in any quarrel of a private nature, until after the expiration of the term of service he had vowed to devote to the deliverance of the holy sepulchre. In like manner, let them forget all their private piques and quarrels, and devote themselves, heart and soul, to the accomplishment of the work they had proposed to themselves. He had trespassed too long upon them (cheers; no, no); but they should bear with him for a very short time, while he noticed some remarks which had been made relative to the Committee of the National Association. It had been stated that that Committee was elected a permanent Committee at the last public meeting, without its members being mentioned by name! With regard to the latter part of the charge, what did it amount to? Simply to this, that at the worst the Committee had fallen into an error of judgment; and as to the first part of the accusation, it was perfectly groundless. He considered that he had some knowledge of the general constitution of committees. He believed that these were usually classed into preliminary or provisional, standing and permanent committees. Before the public meeting of the 14th ultimo, that Committee was a provisional one, and by the resolution, which had given so much offence, it was constituted *not a permanent, but a standing Committee*, which had refused to make bye laws for its guidance for this simple reason, that being but a standing committee, and not finding those laws enacted before, it possessed no power to pass them. Having thanked the meeting for the attention with which he had been listened to, Mr. Mann sat down after moving, "That this meeting expresses its satisfaction at the manner in which the Committee of the National Association has been constituted, and that that committee possesses its entire confidence."

Mr. Van Oven in an able speech of considerable length, vindicated the constitution of the National Association Committee from the charge of *cliquism* which had been brought against it.

Dr. Lynch felt gratified at the tone and temper of the proceedings of the evening, and complimented the chairman at the expense of Mr. Pennington. He treated the meeting to a repetition of the Exeter Hall objections to the National Committee, and referred to the rejection of Mr. Wakley by that body. He next proceeded to inform his audience that distrust was abroad. This assertion of the Doctor's was met by a vigorous and vociferous "No" from all parts of the room. The Doctor again repeated his assertion, and assured "the gentlemen around him that if they consulted the organs of public opinion they would find them corroborative of his assertion." ('Name them,' 'name them.') "Gentlemen might cry out, but that would not put him down or make him retract what he had said. (Cries of 'Name them,' 'name them.') He could and would name them. If gentlemen referred to the *Lancet*——" This reference was immediately followed by a general shout of laughter, which continued for some time, and which proved too much even for Dr. Lynch. After a lengthened peroration on the utility of harmony, the learned Doctor concluded by giving a bird's eye view of the dignity which would result if the profession were generally enfranchised in the "College of the Coopers, the Clines, the Hunters, the Abernethies," &c.

Mr. Sparke, in contending for the right of private judgment for Dr. Lynch, congratulated the meeting on the gentlemanly hearing it had afforded that gentleman. He (Mr. S.) was of opinion that Sir James Graham was entitled to some credit for his good intentions in bringing in the Bill. He commented upon the defects of the Council of Health, and stated it as his conviction—the result of a conversation with Sir B. Brodie—that these objectionable points would be erased from the Bill. After defending the constitution of the Committee, he begged to ask Dr. Lynch why Mr. Wakley had requested to be added to the Committee so long after the passing of the resolution he *now* considered so objectionable?

Dr. Lynch, amid cries of "spoken," replied that Mr. Wakley had *not requested* to be placed on the Committee.

Mr. Wm. Smith, the Secretary, stated that as a member of the National Committee, he considered he had a right to express his opinion on the present occasion. In the observations he was about to make, he felt grieved that he should have to refer to any individual. He was, however, compelled to do so by the remarks which Dr. Lynch had made in reference to Mr. Wakley. Among other matter, he (Dr. L.) had stated that Mr. Wakley had not requested to be placed on the National Committee. If the gentlemen before him would grant him (Mr. S.) a hearing for a very short time, he would state everything connected with Mr. Wakley and the Committee, relative to the transaction which had called forth the latter gentleman's indignation. Sometime after the public meeting of the 14th ult., a letter in Mr. Wakley's own handwriting—of this, he (Mr. S.) was positive, as he had seen and read it—enclosing a cheque for £10, was sent to the National Committee. The gentleman who brought the letter stated "that Mr. Wakley, if elected, would be most happy to serve on the Committee." Now he (Mr. Smith) would not cavil about the strict etymology of the word "request," but he would say that there were such things as *delicate hints*, that, under certain circumstances, were to be considered equal to a request. Among these he would reckon Mr. Wakley's hint. Mr. Ancell, while entering the cheque, asked the gentleman who brought the letter, whether "what he stated was meant by Mr. Wakley as a condition?" To this that gentleman answered "No, no." Accordingly a vote of thanks for his donation, was passed by the Committee to Mr. Wakley, which was not made public, when the following paragraph appeared in the *Lancet*, Mr. Wakley's own journal, in an account of a meeting held in Exeter Hall, subsequent to the delivery of the Hunterian Oration by Dr. Lynch. It was as follows,—

"Mr. Cooper, in reference to a report which he had just heard, would put a straightforward question to Mr. Wakley. Was it true, as he had heard it stated, that the Committee of the National Association had refused to enrol Mr. Wakley among their number?"

"Mr. Wakley would give a straightforward answer to Mr. Cooper's straightforward question. It was true that he had sent the National Association a donation of £10, and that he had proffered to act as a member of that Committee, if his services were accepted. They thanked him for his money, but they declined receiving him as a Committee member, for this reason, that their legal adviser had given it as his opinion that, being a permanent Committee, they had no power of adding to their number." Gentlemen would please to recollect that he was reading from Mr. Wakley's journal. In the paragraph to which he had referred, the word "permanent" was put prominently forward, printed in capitals three or four times larger than the surrounding type. No single word was ever written or spoken by that committee in answer to Mr. Wakley's letter, which, by any misconstruction, could be tortured into the meaning of the word "permanent." (Shame, shame; oh, oh!) That paragraph was an unfounded falsehood, and as gross a perversion of truth as ever was uttered. (Cheers.) And the only thing that he (Mr. S.) regretted in using that forcible language was, that Mr. Wakley was not in that room to hear it. (Hear, hear.) With regard to the five years franchise which had been objected to. That had been taken as the mean of two periods which had been proposed by two associations engaged in carrying out medical reform, and was adopted by the committee as the nearest approach that they could make to what they considered a suitable period of probation ere the young practitioner were allowed to participate in the representative powers of the college to which he may belong. The committee had been also charged with the crime of presenting to the Home Secretary, without the knowledge of the profession, a bill of their own on the subject of medical reform. The charge was a grave one undoubtedly, but would the gentlemen who made it have the kindness to produce that bill? They could not do so—(Cheers)—for this reason, that no bill had been ever drawn up by the committee, and that that which those gentlemen declared to be a true bill—(laughter)—was, on further examination, ignored, and found to be nothing more, nor less, than plain "Suggestions for the Heads of Charter." (Loud cheers, amid which Mr. Smith sat down.)

Mr. Porter would not detain the meeting, but would at once read for them the resolution which had been put into his hands. It was, "that the following gentlemen "(here their names were given)" be appointed a committee to carry out the objects of this association."

Mr. Badger would beg to offer a few observations to the meeting. Though not an active member of the association, nor one who had taken a prominent position in medical politics, still he would say that he had been a medical reformer for a considerable time. He was one of those gentlemen who had heard the delivery of the Hunterian oration, by Dr. Lynch, at Exeter Hall, and was, also, one of those who had then signed a requisition to the National Committee, to call another public meeting. His reasons for so doing were, that he fancied that the committee of the National Association, in appointing themselves a permanent committee, had overstepped their authority, and by so doing had given pain to him and other members of the National Association. Soon after his signing that requisition he received a letter from the committee, wishing him "to express the grounds upon which he (Mr. B.) had felt dissatisfaction at their conduct.' Now in signing the Exeter Hall requisition, he did not think he was expressing dissatisfaction at the conduct of the committee, and he stated so to them accordingly. Since that the constitution of the committee had been so thoroughly vindicated from all suspicion of collusion in its formation, that he felt sorry for ever having doubted it. (Cheers.) Having done justice where it was due, he felt it his duty to refer to another subject. Among the many meetings which he had attended were two during the past week at the Princess' Theatre, Oxford Street, the conduct he witnessed at both of which was quite enough to disgust any unprejudiced observer. At the first, one expressly of members of the National Association, the resolutions were all carried by medical students, who he thought were in the room only for *a lark*. But the result proved that it was for no *lark* that they had gone there. Indeed, he had heard one of the number say, "what a humbug to call this a National Association meeting! Here are we hunted up to support these resolutions." (No, no, from Dr. Lynch—Cries of "shame," and laughter). At the meeting on Saturday evening, the medical students mustered again in considerable strength. And he would say that nothing could be more indecorous than the conduct of Mr. Wakley and the chairman of that meeting, in determining—in opposition to the views of the association members in the room—that medical students should be allowed to vote on that occasion. What right had any but members of the National Association to pass a vote of censure on the proceedings of its committee? Certainly, medical students, though deeply interested in the present scheme of medical politics, had none whatever. He would go further, and state, that even general practitioners, not members of the National Association, had no claim to be heard at a meeting called for similar objects as that on Saturday evening at the Princess' Theatre. In his opinion the members of the association had acted wisely in leaving the room after the decision of Messrs. Wakley and Hillier. Mr. Badger sat down after seconding Mr. Potter's resolution, which was carried unanimously.

Mr. Clarke, of Gerrard Street, as an old medical reformer, though no member of the city association, claimed a hearing. He felt sorry that the words "wilful falsehood" had been used in reference to Mr. Wakley. He was not there directly from Mr. Wakley, but he was grieved that lan-

guage should be used which would tend to widen the breach already existing among medical men, and that the painful duty should devolve on him to have to inform Mr. Wakley that such language as "wilful falsehood" had been applied to any act of his, particularly among a meeting of gentlemen of the city of London.

After a vote of thanks had been passed to the *Times*, and the press in general, for their advocacy of medical reform—to the chairman, for the interest evinced by him to forward the interests of the profession, and for his able conduct in the chair—and to the secretary, for his unremitting attention to his duties as a member of the National Committee, and for his able and untiring exertions in managing the business of that association, the meeting separated.

It was resolved that the foregoing resolutions be advertised, and that a copy of the fourth, signed by the chairman, be sent to the National Committee.

REPORT OF THE NATIONAL ASSOCIATION.

The National Association of General Practitioners have published an extremely interesting document. The following are the members of the COMMITTEE :—

JOHN NUSSEY, Esq., Chairman.

Ancell, H., Esq., 3, Norfolk-crescent, Hyde Park.
Ansell, Thomas, Esq., Bow.
Baker, E. Esq., 13, Bulstrode-st., Manchester-sq.
Bird, James, Esq., 16, Orchard-st., Portman-sq.
Blatch, Henry, Esq., River-terrace, Middleton-sq.
Bowling, J. Esq., Hammersmith.
Brodribb, W. Esq., Bloomsbury-square.
Brown, I. B. Esq., 27, Oxford-square Hyde-park.
Bryant, W. Esq., 50, Edgeware-road.
Chisholme, A. B. Esq., 32, Devon -st., Portland-pl.
Chilvers, T. F. Esq., Burlington-street.
Clayton, J. Esq., 3, Percy-street, Bedford-square.
Clifton, Nathaniel, Esq., Cross-street, Islington.
Coombe, H. Eesq., Caroline-street. Bedford-sq.
Cooke, William, Esq., Trinity-square
Craddock, C. Esq., 6, Chapel-pl. Cavendish-sq.
Dale, G. Esq., } Commercial-road
Dale, G. C., Esq., }
Dickenson, William, Esq., Sloane-street
Dodd, John, Esq., Portman-street, Portman-sq.
Drew, W. Esq., 79, Gower-st., Bedford-square
Davis, Thos. Esq., Hampstead
Eyles, J. B. Esq., St. Andrew's-court
Freeman, John, Esq., 21, Spring-gardens
Fuller, H. P. Esq., 21, Piccadilly
Fincham, G. Esq., 5, Spring-gardens
Grant, N. Esq., 21, Thayer-st., Manchester sq.
Hardwick, A. Esq., Kensington
Hammerton, T. Esq., 111, Piccadilly
Headland, Edw. Esq., 32, Guildford-st., Russel-sq.
Hunter, John, Esq., Tower-street
Harris, H. C. Esq., 1, Windsor-place, City-road
Julius, F. G. Esq., Richmond
James, H. Esq., 4, City-road, Finsbury-square
Lucas, W. O. Esq., 6, Taunton-pl., Regent's-park
Lavies, J. Esq., 34, Great George-st., Westminster
Maclure, William, Esq., Harley-street
Merley, Henry, Esq., Medhurst, Sussex
Morrah, J. Esq., 62, Sloane-street
Moore, E. D. Esq., 10, Arlington-st., Piccadilly
Norton, R. Esq., 11, Oxford-terrace, Hyde-park
Nussey, J. Esq., 4, Cleveland-row
O'Connor, W. Esq., 69, George st., Portman-sq.
Pennington R. R. Esq., 15, Portman-square
Peregrine, J. P. Esq., 3, Half-Moon-st., Piccadilly
Perry, J. Esq., Eaton-square
Propert, J. Esq., 6, New Cavendish-street
Randall, A. M. Esq., 4, Finsbury square
Richards, Henry, Esq., Old Brentford
Robinson, R. R. Esq., Camberwell
Read, Septimus, Esq., 41, Jewin-street
Semple, R. Esq., Islington
Smith, Charles, Esq. Nottingham-street
Smith, J. G. Esq., Trinity-square, *Chairman of the City Association*
Smith, W. Esq. Dowgate-hill, *Secretary of the City Association*
Squibb, G. J. Esq., 6, Orchard-st., Portman-sq.
Stocker, R. Esq., 44, Baker-street, Portman-sq.
Tanner, R. Esq., Manchester-st. Manchester-sq.
Tegart, E. Esq., 36, Pall Mall
Tipple, E. Esq., Mitcham
Toulmin, Joseph, Esq. Hackney
Vickers, W. R. Esq., 32, Baker-st., Portman-sq.
Wakefield, H. Esq., Lansdowne-place
Wansborough, T. W. Esq., King's-road
Ward, N. B. Esq., Wellclose-square
Webster, George, Esq., Connaught-terrace
Wheeler, Thomas, Esq., Gracechurch-street
Wooley, G. Esq,
Webster, G. Esq., Dulwich
Weaver, L. Esq., 2, Dowgate-hill
York, James, Esq., Aberdeen-place, Maida-hill

The report gives the substance of the discussion which preceded Mr. Wakley's rejection from the Committee. Mr. Ancell having briefly but broadly explained the very disgraceful way in which the Association was treated by the conspirators:—

Mr. N. Clifton, of Islington, rose and expressed his regret that Mr. Wakley had shown by his conduct his want of cordiality with the National Association. In the first instance, he had distinctly stated his desire to act as their advocate in Parliament, but not to identify himself with any Association, yet now he wished to become a Member of this Committee. The Committee having been appointed specifically, had not the power to add to their number. To usurp such a power would be an injustice to those Members of the Association who, in appointing the Committee, chose the individuals in whom they had confidence, and to increase the number, but more especially to render the meetings *open*, would give a preponderance of influence to the London Practitioners. The interpretation of the resolution, that the Committee have not the power in question, is strengthened by the fact, that in appointing *preliminary* Committees, it is usual to give them the power of adding to their number, and the absence of such a provision on the occasion evidently marks, that such power was not intended to be given again; it would be an anomaly in public business that delegated power could be re-delegated. Mr. Clifton accordingly felt that the question might rest upon the simple fact, that the Committee have not the power to comply with Mr. Wakley's request;—but he thought it more straight-forward to state his views explicitly, that if the Committee had the power, it would not be expedient to elect Mr. Wakley, that gentleman had pursued such a vacillating course, coquetting between the Protection Assembly and this Association—sometimes supporting the *one*, at other times the *other*. The *recent* reports in the *Lancet*, with reference to the General Meeting at Hanover Square, as well as of a meeting at Exeter Hall, place it beyond doubt, that he is inimical to the National Association. And to complete the proof Mr. Wakley attended and spoke at a "HOLE AND CORNER" MEETING, PROFESSEDLY, but DISHONESTLY, CONVENED as a Meeting of the National Association, without the knowledge or concurrence of the Committee; at the same time taking care that the Committee generally should not be summoned.

Under these circumstances, Mr. C. felt that it would be folly to expect any efficient support from Mr. Wakley, and proposed the following resolution.—satisfied that the Committee possessed the confidence of the Profession generally, and that, however these attempts by a small party to promote discord, might be regretted, yet the only way to meet them was by a firm and straight-forward course, honestly and diligently carrying out the duties committed to them.

"That this Committee, as at present constituted, not having the power to increase their number, are obliged to decline the application of Thomas Wakley, Esq., to elect him a Member of the Committee :—in doing so, they desire to express, that it has always been their wish to treat that gentleman with the utmost courtesy and respect. They very much regret, however, to find by a report in the last number of the *Lancet* of a meeting held at Exeter Hall, on Wednesday the 19th inst., that in his *presence*, and *evidently* with his *acquiescence*, observations were made, highly derogatory to this Committee; manifestly intended to destroy the unanimity which happily prevails among the Members of this Association; and obviously calculated to defeat their ultimate objects.

"It has been the anxious wish of this Association in all its proceedings to pursue a temperate course and to avoid any co-operation with *that small portion* of the Profession who appear desirous to adopt extreme measures; at the same time, they have been solicitous to act with firmness, in advocating the just claims of the General Practitioner, and in endeavouring to place him in that position in society to which his scientific and professional acquirements so justly entitle him."

Mr. Fuller commenced by stating his conviction that the Committee had not power to increase its number. He observed that with respect to Mr. Wakley, he had been represented by some persons in that room as one who was powerful for good or for evil, and therefore to be courted, and his anger avoided. For his own part he doubted if it could be shown that the Honourable Gentleman had ever done much good for the profession at large. But waiving that point, he would confine his observations to the part he had taken in reference to this Association. It is true that during a certain period of its progress he did advocate the Members of the Profession enrolling themselves, but subsequent events made him (Mr. F.) doubt whether that was done with a sincere desire to benefit it. He neither sent a donation, nor proposed to enroll himself as a member nor *requested* to be placed on the Committee, which could at that time have been done without any difficulty. *He, however, sent a message that if we would pay the debts of the Protection Assembly they would join the Association.* He mentioned this, not of his own knowledge, but as having heard it so stated in the Committee-room, and the statement had been borne out by Dr. Lynch having gone to a meeting of the old society of Surgeon-Apothecaries, for the purpose of asking them to give the Protection Assembly a hundred pounds. Mr. Fuller then alluded to an interview which took place between a deputation from the Provisional Committee and Mr. Wakley, and stated his surprise that a sort of demand was made by Mr. Wakley upon the deputation, *that if the Committee expected help from him, they should desist from advertising in the "Medical Times,"* because the editor had insulted him. Mr. Fuller maintained that if any body of men were equal, those of our profession should be so, considered both as Gentlemen and Independent men. But Mr. Wakley did not appear to him to think so, for the next thing he did was to send a message, at least so he understood it, that he would attend our Public Meeting if specially invited. We did not think proper so to invite him, and as far as was known to him he did not attend; but at the Committee, held an hour before the Public Meeting, Mr. Cooper, a friend of Mr. Wakley's, presented himself to demand that some of the resolutions should be changed; and as a motive to urge us to it, stated he had been two hours with Mr. Wakley—as if his name would frighten us out of our propriety. What took place at the Public Meeting all here know full well, and Mr. Wakley must have known equally well, as he had a special reporter in the room, or at least it was to be presumed he had. Well, the next step was that at the meeting of the Committee, subsequent to the Public Meeting, he sent his name for enrollment with a donation of ten guineas, and a desire to have his name added to the Committee. This was met in the most courteous manner; thanks were voted to him for his donation, and he was informed that the question of his being added to the Committee was postponed for a week, on account of some doubt as to the power of the Committee. But how did he act? Why, he went to a meeting at Exeter Hall, the very next day, supported Messrs. Lynch and Cooper, and from his own account of it in *The Lancet*, you may judge what he said and did; and when you farther learn what he said and did, on Saturday night, at the Hotel in George Street—Mr. Fuller continued—"*I would ask if that man is to be considered a sincere friend of this Association, or if his conduct tends to elevate the character of the profession, whose bond should be peace, unanimity, and concord.*" For himself Mr. Fuller would a thousand times prefer an open enemy to a false friend

and cordially seconded the motion of Mr. Clifton.

Several members addressed the chair expressive of their deep regret at the circumstance, and particularly that Mr. Wakley should have so placed himself with the Association; but intimated their full concurrence in the resolution. The resolution was carried unanimously.

Moved by J. W. Wansborough, Esq., seconded by J. Bowling, Esq., and carried unanimously, that the resolution be forwarded by the chairman to T. Wakley, Esq., accompanied with the following letter :—

4, Hanover Sq., March 24th, 1845.

SIR,—On the part of the Committee of the National Association of General Practitioners in Medicine, Surgery, and Midwifery, I have been requested to address you to the following effect.—

The Committee had much pleasure in receiving your name for enrollment as a member of the Association, and your donation to its funds, on Tuesday last, immediately after the public general meeting lately held; believing this liberality on your part to be a substantial proof of your approval of the Association and of the proceedings of the Provisional Committee, and an earnest of your intention to give your assistance to the Committee in furtherance of the objects sought by the General Practitioners of this country. The Committee did not for one moment entertain the notion that the gift on your part, or the acceptance of it on theirs, had any reference whatever to the question that immediately followed, in which you were individually concerned—viz., your election as a *member* of the Committee.

This having been the feeling of the Committee at the period alluded to, they now beg to express their surprise and regret at the appearance, in your own journal, of a report of certain proceedings at Exeter Hall on the following Wednesday evening, to which you appear to have been a party; and of certain language, also reported under the sanction of your name, without comment or disclaimer from you, as having been employed there in your presence, the object of which language and proceedings can be no other than to divert the attention of the Committee from the urgent business which they must now seriously engage in—to prejudice the public mind against the National Association before the opportunity has been afforded it of taking any measures whatever,—and to injure, through the National Association, the cause of the General Practitioners of this kingdom.

Until these latter circumstances occurred, the Committee would have deemed it an injustice to you to doubt the object of your adhesion to the Association, but they now regret to say that the character of these transactions, as they present themselves, compels the Committee so to do; and without intending more or less than to avoid misunderstanding, I am requested to intimate to you, that if there has been any mistake on the part of the Committee as to your intention in forwarding a donation to the funds of the Association, they will return it upon hearing from you to that effect.

In reference to the remarks in your journal, I am requested, in fine, to state (which the Committee still trust your own experience and judgement will confirm the propriety of)—that for themselves, and for an immense majority of their constituents they could not allow the National Association to be otherwise than a deliberative body. They have declared themselves in favour of a representative and a responsible government, but regarding their profession in a philosophic point of view, they believe that peace only is consistent with its pursuits, and they will never be parties to any measure which would engender unnecessary public discussions and declamation, leading to personalities, quarrels, and cabals, and tending to perpetuate political strife.

Enclosed is a copy of a Resolution adopted unanimously by the Committee, at which forty-seven members were present, yesterday afternoon.

I have the honour to remain, Sir,

Your obedient Servant,

(Signed) JOHN NUSSEY, *Chairman.*

Thos. Wakley, Esq., M.P.

&c., &c., &c.

The office is changed to 294, Regent Street, and we understand that subscriptions and enrollments of names are coming in extremely fast.

THE PLOT MEETING.

On Saturday evening, the 29th instant, an adjourned meeting of Mr. Wakley's friends and supporters—now reduced to students, the *gentlemen* of University College—was held, pursuant to notice, at the Princess' Theatre, Oxford-street. The number of persons present was about that of the previous meeting. The gentlemen on the platform were Messrs. Curtis, Obré, Rugg, Gray, O'Connor, and Lynch, with the chairman, and Mr. Wakley. The chair was taken by Mr. Hillier, who presided over the former meeting on Wednesday. He opened the proceedings by telling the assembly, that they all knew what it was that brought them together on that evening, namely, to hear the answer given to the deputation from the *National Association*, that had, on that day, waited upon the Committee sitting at the Hanover Square Rooms. He regretted to say, that the result of their interview was most unsatisfactory, and that the Committee had not, in fact, treated them with proper courtesy. The deputation, appointed at the former meeting, had gone to Hannover Square that evening, at four o'clock, where they had been delayed so long, that it was only by great exertion that they were able to meet their professional brethren in that room, even at that very late hour. He would read for them the answer of the Committee. It was to this effect—"that they, the Hanover Square Committee, did not think proper to introduce into Parliament, at the present juncture, any bill of their own framing, when a medical bill, brought in by a member of the Executive, was lying before the House for its consideration; moreover, for this additional reason, that arrangements were at present pending between the Committee, the Corporations, and the Legislature; that they were of opinion, that bye-laws were not necessary for the government of their Committee; and that at present they saw no reason to call a public meeting of General Practitioners, but would do so whenever they thought it necessary or expedient."

Mr. Curtis, of Camden Town, moved the first resolution, condemnatory of the National Association Committee, on the ground of censure furnished by their answer to the deputation.

Mr. Obré, of Lisson Grove, rose to second the resolution.

Mr. Herring, so we caught his name, rose, amidst cries of "Name! name! sit down!" &c. The uproar continued for some time, until put an end to by the cries of the chairman for "order." "He could not tell," he said, "for what purpose the present meeting had been called, if it were not for the purpose of exciting division among medical men, at a time when they had need of the utmost harmony among them. He would ask any of the gentlemen who formed the deputation to Hanover Square that day, what it was for which they condemned the conduct of the National Committee? He wished to state a fact connected with the last meeting held in that room. It would be in the recollection of the chairman, that on that occasion, an amendment to the first resolution had been moved by Mr. Brett, 'that this meeting be adjourned *sine die*,' and which amendment was the signal for uproar and tumult in that room. Now, the first resolution was strenuously opposed by Mr. Brett and another gentleman, and a considerable period passed before it was carried. When it was put from the chair the last time, it was spoken in such a low tone, that, owing to that cause, and to the uproar, which even the chairman's authority was not strong enough to silence, it was quite unheard where he stood. Not hearing what the chairman said, and imagining that it was Mr. Brett's amendment that—as he should have done—he was proposing, he (Mr. H.), along with several other gentlemen, voted for the resolution under a mistake, which he took the present opportunity of correcting."—(Hisses and groans—Oh! oh!)

Mr. Wakley said, that it was very probable, that as the gentleman who had spoken last had been on the last evening so much in the wrong, that he was not this evening quite in the right. The hon. gentleman then proceeded to condemn the conduct of the Hanover Square Committee, and after a few observations sat down.

A Mr. Wadman said, "A single speck would stain snow," "The path of duty was straight, but it was also very narrow," "Principle should always guide our actions," &c. He *expectorated* a speech of such very heavy matter, of so equivocal a character as to which side it defended, and couched in such ambiguous language, that it produced rather an unpleasant effect upon the countenances of the gentlemen on the platform, which became visibly elongated. His bathos was suddenly checked by Mr. Wakley, who, on the speaker making use of the words, "I condemn that resolution," asked him, "what resolution he referred to?" "What other could it be," answered Mr. Wadman, "than that most unconstitutional one, which has made the Hanover Square Committee permanent." This *auto da fe* was received with *all the honours* by the aspirants to medical fame, and Mr. Wadman, after uttering certain unintelligible language about the poisoned shirt of Nessus the Centaur, sat down in a heat, which necessitated the use of his handkerchief as a fan for some length of time after he had concluded.

The Chairman moved that the first resolution be adopted.

A gentleman whose name we could not learn, said that no one, save members of the National Association should vote on the passing of that resolution, conveying as it did a censure upon the Committee of the National Association. He was well aware how the resolutions had been carried on a previous day.

The resolution was again put, and negatived, the remarks of the last speaker having produced some effect upon the students, very few of whom declared in its favour.

It was *again* put, and negatived, when Mr. Wakley rose and said that this meeting not being convened for the especial attendance of members of the National Association, he thought that every one in the room, who was concerned in the measures of medical reform contemplated at present, had a right to vote for the resolution, or against it as they thought fit.

A gentleman from the body of the room, suggested that none but men actually in practice should have a voice for or against the resolution. This was agreed to by the person who moved that none but members should vote, but was negatived by the Chairman, who said he would use the power vested in him as Chairman, by allowing every one present to vote as he pleased.

The resolution was then put and carried by a majority.

Immediately on the above decision of the chairman being announced, all the members of the National Association, amounting to about 30, stood up and left the room, vehemently protesting against the conduct of the chairman.

After some short altercation, in which the chairman called Mr. Craike "a porter," "a door-keeper," &c., Dr. Way protested against the manner in which the resolution had been carried and condemned the meeting as tending to excite disunion among the profession, for the furtherance of objects of a partisan nature.

Mr. Cooper of Saint Pancras, declared he was no party man, but yet was strongly opposed to the Association, into whose Committee he had not been elected.

A Mr. Gray next made his bow to the meeting. As in the olden mysteries, or dramatic representations, a clown was introduced as a foil, so on the present occasion, the managers of the exhibition produced Mr. Gray. After jerking from his seat, somewhat in the manner that *Punch* makes his entrée for the first time before his audience, Mr. Gray in a tone of voice suspiciously akin to that of the denizens of Holywell-street, informed the meeting "that he was somewhat like Balaam's ass! inasmuch as he required a little of what medical men termed the *Vis a tergo*. In other words, he was not by any means a public character; never having made his appearance before a meeting until last Wednesday. He was

sorry to see a young man like Dr. Way coming forward for the sake of giving opposition. By such conduct, he made himself like nothing in the world *but an old buck goat!*" After a liberal display of such elegant *facetiæ*, this gentleman proceeded to give an account of the reception of the deputation that day at Hanover Square, and of the effect which the sight of it produced upon the members of the Committee, "*Every one of whom looked as if he had a bunch of nettles at that moment in the seat of his breeches!*"

Dr. Lynch, proposed a vote of thanks to the chairman. He said that he had been for sometime a medical reformer—a part which he gloried in time having assumed—said he was not like the fish of the class "Rodentia!" in Cuvier's arrangement, which followed the ship in fine weather, but deserted it when a storm came on; unlike it, he would follow up through fair or foul weather, the cause he had once espoused, and from which no calumny could ever force him to depart. The meeting separated at twelve o'clock, after a further speech from Mr. Wakley, who seemed anything but made happy by the meeting before him, or by the prized reception his tergiversations had previously got him from the Committ ee of the National Association.

THE MEDICAL PROTECTION ASSEMBLY.

The usual weekly meeting of this body was held on Monday evening, at their room in Exeter Hall. Among the gentlemen present, fourteen or fifteen in number, were T. Wakley, Esq., M.P., Dr. Lynch, Messrs Curtis, Hunter, Hodson Rugg, and Simpson. The only circumstance that occurred to distinguish the *conversazioné* of Monday from the preceding *reunions* of the "assembly," was the introduction of a Mr. Officer from Belfast, who gave it as his opinion, "that the apothecaries of Ireland wanted protection!—that they should be restricted to the practice of pharmacy, beyond which they should not be allowed to travel!"

No business of any importance was transacted. The meeting broke up after coming to a resolution to call a meeting of their entire sub-committee on Thursday at two o'clock, to appoint a deputation, to wait, on Saturday, upon Sir James, Graham, who had promised to grant them an interview.

MR. WAKLEY AND THE MEDICAL TIMES.

(Copy)

MY DEAR SIR,—Hearing that Mr. Wakley has resolved on the wisdom of carrying his character into a court of justice, I take' leave to send my mite as aid to you in the discharge of the public duty of doing him justice. Reparation and retribution will, I am sure, be your motto in your campaign for right; the battle is far less your's than the profession's, and if all think like me, the "sinews of war" will be furnished in sufficient amplitude by those for whose good it is waged. With best wishes for your continuous prosperity, and sincere hope that no bills of costs—always lengthy, I am told, in these cases—will come in to slacken your career of utility,

Believe me,

Ever yours faithfully,

E——.

P.S. If a public journal have not the right to call on a public man to set his character clear with the profession he pretends to represent, the sooner we have the law altered, the better for the public interests. Every blackguard will be a public character if no one dares call him to book.

[We have to acknowledge, with cordial thanks, the enclosure of ten pounds, adding our regret that our correspondent will not allow us to testify by name to his munificent contribution. It is quite true, as is now generally known through London, that Mr. Wakley has commenced an action against us for inserting a letter (signed Vindicator), proposing an investigation into his character in its relation to the profession and the public, and that in his "*declaration*" (his legal complaint), he affirms that the suggestion of such an inquiry has positively deprived him of the society and good opinion of numerous friends, and incurred for him a damage, in the way of *good* repute, which he estimates at the incredible sum of £2,000—a sum which he therefore claims from us!. The trial will be brought to the earliest possible decision.—ED.

TRANSACTIONS OF LEARNED SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, March 25, Dr. Chambers, President, in the chair.

On the Minute Structure of the Lungs, and on the Formation of Pulmonary Tubercle, with some Observations on its Detection by a Microscopic Examination of the Sputa, by George Rainey, Esq., M.R.C.S.E. Communicated by R. D. Grainger, Esq.

THE author, in his prefatory remarks, observes that it is not his intention to introduce any new speculations on the structure, functions, and pathology of the lungs, but only to bring forward such facts as readily admit of verification by the microscope, and to deduce from them, what he considers as obvious and legitimate inferences.

He divides his subject into four parts: 1st. The anatomy of the lungs as applicable to their physiology. 2nd. With reference to their pathology. 3rd. The mode of formation of the tubercle. And lastly, its detection by a microscopic examination of the sputa.

The first division contains a general description of the lungs of the reptile, shewing the alterations they undergo, as they approach in complexity the same organs in the mammal. The principal difference between the lungs of the reptiles and the mammals, is the existence of a double layer of vessels between contiguous air-cells in the former, and only a single one in the latter. The author shewed that a great difference of vascularity exists in the different parts of the same lung, those parts being least vascular which are furthest from the principal air tubes, consequently the quality of blood requiring the influence of the inspired air is adapted to the diminution of oxygen in the remote cells, in which, he considers, the renovation of their contents is due more to the law of diffusion than to mechanical dilatation and contraction of the chest.

The author describes minutely the manner in which the bronchial passages communicate with the air cells and with each other, the actual terminus of a bronchial passage being itself a cell at the surface of a lobule, or several cells connecting one bronchial passage with another. It is further shown that each plexus of capillaries is situated in a fold of membrane, forming the immediate wall of the air cells; hence the author infers there must be cellular tissue in the lungs connecting the folds of membrane together.

He combats the opinions of Mr. Addison with respect to the non-resistance of air cells in the fœtal lung, and shows by microscopic preparations that this opinion is erroneous. He is inclined to deny the existence of muscular structure in the minute bronchial tubes, both from the absence of anything like muscular fibre in the pulmonary membrane, and also from the fact that the connection of the bronchi with the cells appears to be such as not to admit of any constriction of these passages, even were muscular fibre present. A description is next given of the manner in which tubercle is formed by the deposit of tubercular matter in the air cells, occasioning by its pressure absorption of the intervening capillary plexuses, the membrane still remaining. The author remarks that the vessels close to a tubercle, and even those of the cells in which the deposit is not sufficient to cause their obstruction, retain perfectly their natural character, while those near to cells filled with fibrine from inflammation have a tortuous and knotted appearance; hence he thinks the deposit is not the result of inflammation, but merely an altered secretion. The observations on the formation of tubercle are confined to those of which the author has had the best opportunities of examining. He considers that it is only in preparations of injected lung that the exact extent and situation of tubercular matter can with certainty be ascertained. He offers no opinion respecting miliary tubercle, having only once examined it, but the facts respecting the formation of common tubercle the author considers are unconnected with the consideration of any other form of phthisis, inasmuch as his preparations exhibit the tubercular deposit in all the different stages of common tubercle, from a quantity so small as to fill only a small part of a cell, up to that filling one, two, or even an indefinite number of cells—in all the preparations the tubercular deposit exhibits the same microscopic character. Lastly (from the fact that the pulmonary membrane does not become absorbed), the author proposes a method of detecting tubercular matter by a microscopic examination of the sputa. Although the observations he has made are not sufficient to enable him to speak with confidence of the practibility of this mode of diagnosis, in one instance he succeeded in detecting the pulmonary membrane in tubercular matter, washed from the trachea of a phthisical patient, with perfect ease and certainty.

Mr. Grainger said, that having had many opportunities of examining Mr. Rainey's preparations, and of observing the progress of his inquiries, he thought that it might be desirable that he should state his opinions respecting the paper which had just been read. The question relating to the intimate structure of the lungs was one of admitted difficulty, and he believed that no anatomist was satisfied with the accounts hitherto given. That of Reisscipers was certainly erroneous, and although in several respects the inquiries of Mr. Addison more nearly approached the truth, yet much had remained to be cleared up and explained. He thought that a chief excellence of Mr. Rainey's investigations consisted in this—that they tended to introduce clear ideas upon this intricate subject, by demonstrating the precise relations of the ultimate bronchial passages, of the air cells, and of the vascular capillary plexuses. There are also several new and interesting facts disclosed, especially the disposition of the air cells with respect to each other, for it was certain that these were placed in planes opening into each other, so as to form in each lobule of the human lung, a miniature representation of the entire lung of the frog or toad. It had been affirmed by Mr. Addison that the air cells did not exist prior to respiration, but Mr. Rainey had, at his suggestion, examined the injected lungs of several fœtal animals, and, as might have been anticipated, found the air cells in successive stages of development, and at length fully formed) independently of the admission of air by the bronchi. It was also interesting to find that the air cells regularly enlarged as they approached either the pleural surface or the exterior of each lobule, whilst at the same time the vascular plexuses became much more open, presenting, that is to say, larger areolæ, and at the same time only one instead of both sides of the vessels to the air. This arrangement appeared to be connected with the mode in which the air contained in the lungs was renewed; for whilst in the larger bronchial tubes, and even in those air-cells immediately opening from them, the air was changed by the inspiratory and expiratory forces, in the deeper and smaller tubes, and in the more remote cells, there was reason to believe that the air was renewed on the principle of diffusion. Mr. Rainey had further demonstrated a set of curved fibres of an apparently elastic character, definitely surrounding the mouth of each air-cell, thus keeping it patent, as in the similar instance of the trachea of the insect. These observations also distinctly proved, that at all events, in many cases, the matter of tubercle was deposited in the air-cells where it could be seen in isolated masses.

Dr. C. J. B. Williams agreed with Mr. Grainger in commending that part of the author's paper which related to the minute anatomy of the lungs, confirming, as far as it went, the description of M. Bourgery, and corresponding pretty closely with the observations of Mr. Addison, which he (Dr. W.) considered highly valuable in themselves, but as by no means warranting the conclusions which Mr. Addison had drawn from them with regard to the first formation of the vesicular texture of the lung. Dr. W. could

not equally approve of Mr. Rainey's remarks on the pathology of the lungs, especially as regards the first seat of tubercular deposit being on the free surface of the air cells. To discover the first seat of tubercle in a texture so extremely delicate as that of the lungs, it would be necessary to examine many specimens in the very earliest stage of its deposition, before by accumulation it makes its way through the epithelium to the free surface of the cells, yet Mr. Rainey acknowledges that he has examined only one specimen of miliary or incipient tubercle. Mr. Gulliver, on the other hand, had distinctly discerned the opaque granular matter of tubercle in repeated instances in the walls of the cells, and even in the vascular plexus itself. Some of Mr. Addison's observations were to the same effect, although he too, like Mr. Rainey, had taken up the notion that tuberculous matter is altered epithelium. But that tubercle is not an altered secretion of mucous membranes, is sufficiently proved by the fact that tubercles appear in the parenchyma of organs without mucous membranes, such as the spleen, the brain, in serous membranes, and he (Dr. W.) would add, in the interior of blood vessels. He considered that their nature and origin were very intelligible on another view. In his remarks on the obliteration of the blood vessels of the lungs by tubercles, Mr. Rainey had been anticipated by many pathologists, particularly by M. Natalis Guillot, whose researches proved that the obliterated vessels were often compensated by increased anastomosing vessels not only in the remaining healthy pulmonary texture, but in the pleura, and through adhesions to the costal pleura, even in the external walls of the chest itself, a fact which explained what we are all familiar with in practice, what signal relief is often afforded in phthisis by a few leeches, or a blister to the walls of the chest. Dr. W. wondered that the author had thought it necessary to make any remarks to disprove the muscularity of the pulmonary texture, the non-existence of which was sufficiently established by his (Dr. W.'s) experiments, in which galvanism detected no contraction in the vesicular part of the lungs, although it caused it most evidently in the bronchial tubes.

Dr. Kingston expressed his gratification at finding in the valuable paper which had been read, a confirmation of the views advocated by him some time since in a paper published in the transactions of the society, respecting the vascularity of tubercles. He had then stated, and his opinion had been since confirmed by M. Lugol, that red vessels had been discovered in tubercle of the lungs under the microscope. Mr. Rainey's series of injections of tubercular lungs had added force to his observations. The failure of the injection in some of Mr. Rainey's experiments, and his own occasional non-discovery of red vessels, was owing, he (Dr. Kingston) thought, to the exceeding minuteness of the nutrient vessels of tubercle, which do not carry red blood, unless when congested or inflamed. In those instances in which they had been discovered, they seemed to be subservient to the process of nutrition, and he believed that they were connected, either by their direct action, or by their obstruction, with the various changes which tubercle ultimately undergoes.

Mr. Prescott Hewett stated that he did not see how Dr. Kingston could think that the views expressed by the author of the paper, concerning the vascularity of tubercular matter, agreed with the views entertained by Dr. Kingston. Mr. Rainey had distinctly stated that his observations had led him to the conclusion that tubercular matter was not vascular, whereas the opinion expressed by Dr. Kingston was directly opposite. The minute vessels which might sometimes be seen in a tubercle did not belong to it, but were merely some vessels of the neighbouring tissues, which had been entangled in the morbid deposit. In a very successful injection of a liver filled with large tubercles, Mr. Hewett had found but one or two small vessels passing into the tubercular matter, and that only in one or two tubercles; in all the other tubercles a distinct areola of vessels might be seen completely encircling them, as if the vessels of the normal tissue had been pushed out of their places, and compressed together, by the deposition of the morbid substance. With regard to the deposition of tubercular matter on the free surface of a mucous membrane, Mr. Hewett agreed with Dr. Williams in thinking that the views of the author of the paper ought to be received with very great caution, especially as Mr. Rainey had only once examined some miliary tubercles under the microscope. Mr. Hewett then pointed out how Dr. Carswell had been led into error upon this very subject. In Dr. C.'s pathologic plates there was a specimen of a scrofulous kidney, given as an example of the deposition of tubercular matter upon the free surface of a mucous membrane. Now, Mr. H., who had had several opportunities of examining similar specimens in an early stage, had frequently found the tubercular matter in the sub-mucous cellular tissue, the mucous membrane itself being healthy; and in two or three instances he had found the mucous membrane partially destroyed by ulceration, and the tubercular matter apparently situated upon its free surface. In the more advanced stages of the disease all mucous membrane had completely disappeared. The course which this disease followed could be easily traced in the bladder, whenever it had spread so far. All the appearances above alluded to Mr. Hewett had several times observed in this organ. Mr. Hewett was quite ready to admit that tubercular matter was sometimes deposited upon the free surface of a mucous membrane, but he could not agree with Mr. Rainey in thinking that this was always the case.

Dr. Hodgkin confirmed generally the opinion of Dr. C. J. B. Williams with respect to the seat of tubercle.

Dr. Golding Bird observed, that there were two or three points to which he was anxious to draw the attention of the society. Mr. Rainey seemed to have satisfied himself that the lining membrane of the air cells was really a mucous membrane. This he (Dr. Golding Bird) thought was hardly proved by its pathology. A mucous membrane under common inflammatory action secretes mucus, destitute of free or coagulable albumen, but the lining membrane of the pulmonary cell in ordinary pneumonia, secretes a large quantity of free albumen, and hence the scanty yellow, or rust-coloured sputa of pneumonia coagulates like white of egg, on the application of heat. Again, in the state of grey hepatization, sometimes in persons of weak power, left long after the subsidence of the acute stage, the cells are full of a substance to all intents nearly if not quite identical with coagulated albumen. Hence, although the lining membrane of the cells cannot be from its anatomical relations, considered as a serous membrane, yet, in its pathology, he thought it approached such a structure more clearly than a mucous membrane. With regard to tubercle itself, he agreed in the important remark just made by Dr. Hodgkin, that it was scarcely possible to discriminate between pneumonic deposits in the air cells, and the so-called tubercle. Regarding Mr. Rainey's test for phthisis, and the microscopic appearance of the sputa, there is nothing new; the only fact suggested by Mr. Rainey as possessing merit, viz., the presence of portions of air-cells in the expectorated matter, has been for some time pointed out by a talented pupil of Professor Valentin's, Dr. Buhlmann, of Berne. He in his thesis on the microscopic structure of expectorated matter, has given figures of broken air-cells in the sputa of a case of phthisis, mixed with which often also occurs, fine plates of cholesterine. This test is, however practically, useless, for when we most need its aid, as in early phthisis, it fails, and when it really succeeds, as in advanced disease, where large excavations are present, the ordinary physical signs render it unnecessary.

DR. CLAY'S REPLY TO DR. LEWINS.

March 30th, 1844.

SIR.—The announcement in the *Medical Times* of 22nd inst. puzzled me no little, never having addressed you, nor having heard of your name: and now the promised answer appears, I am equally at a loss in what character to consider you, whether lion's provider or lion's defender, perhaps the latter is most apt, as the lion may use his provider, but never expects to be defended by one of inferior strength. Mr. Liston may thank you for your good intentions and exclaim *"leave me to my enemies, but spare me from my friends."* Mr. Liston's career is known as well to me as yourself; and I yield to no man, (not even you) in my admiration of his brilliant talents as a surgeon, but I am neither so bigotted as to deem him infallible, nor so blind as not to see his faults. I challenged him for illiberal expression of opinion, on a subject on which he had had no experience, and stated that such was contrary to good professional feeling, and a foe to improvement in medical science, and when Mr. Liston (or yourself) are prepared to meet me with equal experience in controversy, I shall ever be found ready to defend my own propositions.

I cannot pass unnoticed one of your errors, you say, "the entire body of the profession in modern Athens coincide with Mr. Liston in condemning ovariotomy." The celebrated Professor of midwifery, of whom you speak so highly, is not only a valued friend of mine, and an advocate for the operation, but the very person who suggested to me in lieu of peritoneal the sectionword ovariotomy, which I have ever since used and preferred. Mr. Lizars you must also rank on my side, and I could adduce documentary proof of others *all good men and true* in Edinburgh, Glasgow, and almost every other part of Europe and America, in favour of the operation. Sir C. Bell's opinion is like Mr. Liston's a prejudiced one, wanting experience and practice to make it of value. The most amusing part of your letter is the ruse to make public an amputation of neck of the womb, performed *by your son*, which has as much to do with the subject in question as the man in the moon. What a pity it is that I did not know you sooner, I might have invited you to Manchester to witness *one*, out of the many successful cases I have had, and thus convinced *all* the world, even Mr. Liston, of the legitimacy of the operation, and secured the triumph of ovariotomy. Mr. Liston little needed your help to defend him, he could much better have defended himself, but then your son's name might not have been brought before the public. It certainly was a good move to revive it with the names of Sir C. Bell, Professor Simpson, Liston, Lizars, and myself. I hope your next communication may contain suggestions worthy of consideration, from which I, as well as the rest of the faculty may derive advantage.

I am, Sir,
Your's &c.,
CHARLES CLAY.

To Dr. Lewins.

EPIDEMIC AT GIBRALTAR IN THE MONTHS OF FEB. AND MARCH, 1844.

By J. B. THOMPSON, A.M. M.D., &c.

(Communicated by Dr. Hodgkin.)

On my arrival here from England, on the 9th instant, I was informed that a disease of a very acute form was witnessed here during the above months, and that very many persons died thereof. It is stated that all classes were alike subject to its attacks, especially those between the ages of puberty and adult life. The first indications of the disease were noticed to be a total and general prostration of all the vital powers—the head especially became engaged, the persons soon lost all power of reasoning, and shortly became incoherent, evidently labouring under active and diffuse inflammation of the arachnoid membrane; which was fully verified in some autopsies, which I understood Dr. Gilchrist had an opportunity of making. During the early stages of the disease, it was not unusual to observe the patient affected with spasmodic twitchings of the muscles of the side and back of the neck, so that the head was sometimes forcibly and convulsively thrown back or to one side. There were several deaths during these months, and only a few instances of recovery known to my informant, and these only in young and previously healthy subjects, and even they up to the period of my departure, experienced some inconvenience from the spasmodic affection alluded to, which appeared to assume a somewhat persistent form.

The treatment that was found most successful in these cases was general depletion, and active and vigorous antiphlogistic remedies; but so sudden was the seizure and so rapid the fatal progress of the disease, that there was very little time left for the more extended operations of the medical attendant. The disease has since then disappeared; there were no cases of it amongst the troops, which one would expect to find, did it arise from intemperance or incautious exposure to a tropical sun or night chill. It appears that some cases somewhat similar in their symptoms, progress, and fatality, have been lately met with at and near Rome and in other parts of Italy. I have only given you these few notes, taken hastily as I passed through here, hoping that they may elicit some remarks from yourself or others. I made inquiries of the medical officers at Malta and Alexandria, as to their having witnessed any such disease as the preceding in their respective localities, and was answered in the negative. Each of these places has been comparatively healthy especially the former, only an occasional case of plague has been seen in the latter. I have been subjected to twelve days quarantine at Beyrout, a most unjust and unnecessarily prolonged imprisonment, we having sailed with clean bills of health from Egypt.

The thermometer varies here from 78° to 86° in the shade.

PULMONARY APOPLEXY—CONTRACTION OF THE LEFT AURICULO-VENTRICULAR OPENING.—Dr. Favell at a meeting of the Sheffield Medical Society, exhibited the heart and part of the left lung of a woman, who had been under his care in the Infirmary. At the time of her admission she was in a state of great exhaustion, and had been suffering from palpitation of the heart, dyspnœa, and anasarca of the inferior extremities, for several weeks. The pulse was extremely small and irregular, the surface cold, the face congested, and she complained of severe pain in the left side, which was greatly aggravated by inspiration and the effort of coughing. The expectoration consisted entirely of dark-coloured blood. On examining the chest the dulness in the præcordial region was much more extensive than natural, but the sounds of the heart were so entirely masked by the respiration, (which could not be even momentarily suspended,) that no abnormal murmur could be detected. Sibilant and mucous rhonchi were heard extensively over the anterior part of the chest, as well as posteriorly, particularly on the left side, whilst laterally, for the space of four or five inches, there was a distinct loud frottement accompanying both inspiration and expiration. The *post-mortem* examination shewed an extensive deposit of recent lymph on that portion of the pleura which corresponded to the friction sound, but there was no adhesion; the left lung, moreover, in its central and inferior portions, presented a remarkably fine specimen of pulmonary apoplexy; the heart was larger than natural, but its parieties were not thickened, and the left auriculo-ventricular opening was so contracted that it would only admit the end of the little finger.

DISLOCATIONS OF THE HUMERUS.—M. Vergneis published the following mode of proceeding in the *Bulletin Therapeutique*:—The patient being seated on a chair, the surgeon takes the luxated limb, and holds it perpendicularly; he applies one hand to the middle of the arm, the other towards the wrist; he next raises his foot, and placing it under the luxated head of the bone, he fixes it on the chest, and draws the arm slightly towards him, whilst he depresses it in drawing it forwards; he increases the force, at first proceeding quickly. He says he has succeeded where others have failed.

DISLOCATION OF THE HUMERUS.—Mr. Hancock, in the *Provincial Medical Journal*, recommends the following plan for reducing these dislocations. Suppose the case to be a dislocation of the right shoulder. Having applied the wet bandage and a pocket handkerchief, or towel, above the patient's elbow, he should lie down on the carpet on his side, a thick napkin or pocket handkerchief, should then be placed across the sole of the surgeon's right foot, which is to be placed as a soft cushion in the axilla; after which a steady and gradual extension should be commenced, neither attempting nor desiring to pull it in all at once, but the muscles should be kept upon a moderate state of tension, until at length from fatigue they will gradually give way. The head of the bone soon begins to move with a vibration which will be sufficiently evident. The extension should be steadily increased, and the arm brought at once towards the body, when the upper part of the humerus, moving round the firm pad in the axilla, the head of that bone is set at liberty, slips over the edge of the glenoid cavity, and springs into its place, usually with an audible snap. This plan is at once simple and effectual; it is attended, when properly applied, with very slight violence to the soft parts, or fatigue to the patient, while it admits of success in most instances, which have not been so long neglected as to render success under ordinary measures impossible.

A SELECT PRACTICAL FORMULARY.

TRANSLATED FROM THE FRENCH OF M. FOY, PRINCIPAL PHARMACIEN OF THE HOSPITAL ST. LOUIS, AT PARIS.

RHUS. The rhus vernix, radicans, and toxicodendron, have been much formerly employed in the treatment of palsy, dartrous eruptions, and consumption. At present, these substances, which have a powerful action on the nervous system, which give rise, when they are touched, to tumefaction of different parts of the head, and to the appearance of vesicles full of serosity on the parts touched, are very rarely employed. In America, however, the bark of the root of the rhus glabrum is still used in decoction in the form of gargle against mercurial salivations.

RICE: decoction alone, or combined with gum, catechu, &c., half an ounce to an ounce to a quart of water. Used as emollient, and slightly nutritive, in the treatment of phlegmasia of the intestinal tube.

ROB OF LAFFECTEUR. a very concentrated, deeply coloured syrup, prepared with sarsaparilla, smilax china, guaiacum, sassafras, &c. See syrup of Laffecteur.

ROSES, PALE: distilled water, one to three ounces as a collyrium; aromatic syrup, half an ounce to an ounce, as a purgative; extract, half a drachm to a drachm, as a purgative.

ROSES, RED: conserve (simple electuary), one to three drachms on the point of a knife, or mixed with a little water: honey of roses, one to two ounces added to a gargle, or alone as a collutory; infusion, for external use, two to four drachms to a quart of the menstruum (wine, water, &c.) The red roses are an astringent employed much more frequently externally than internally. They form the basis of a pharmaceutic preparation, called the conserve of roses, which is given advantageously in commencing tubercular phthisis, accompanied or not by emaciation or colliquative diarrhea. The good effects of this official preparation have also been shown in atony of the digestive organs, chronic diarrhea, leucorrhea, &c. Infused in strong wine, the Provence roses are frequently employed in surgery in the form of injection, after the operation of hydrocele, to cause the adhesive inflammation of the tunica vaginalis. Treated by water, vinegar, or alcohol, (for their active principles are equally soluble in these menstrua) they serve as gargles, collutories, lotions, and fomentations, in cases of chronic angina, atonic ulcers, &c.

RUBEFACIENTS: rubefaction, the first degree of vesication, employed in the treatment of deeply-seated inflammation, is obtained by the external use of bruised mustard, bruised garlic, powdered pepper, vinegar, tartar emetic, dry cupping, galvanism, moderate heat, very hot water, Burgundy pitch, alcaline, or acid pediluvia, prepared white ash, hydrochloric acid, &c. Dry friction, and friction with the mineral acids diluted with water, or friction with alcohol are rubefacients, which are also often employed.

RUE, ODOROUS. powder, ten to thirty grains in bolus or pills: infusion, half a drachm to a drachm to a quart of boiling water; essential oil, one to four drops in potions, juleps, or mixtures; pulverulent conserve, 40 to 120 grains in bolus or pills. Rue possesses well-marked stimulant and anthelmintic properties. Its special action on the uterus has caused it to be employed with advantage in amenorrhea from atony of the uterine system, in chlorosis, hysteria, &c.

SABADILLINE: a medicine extracted from sabadilla, and as yet but little employed.

SAVINE: a plant containing a great deal of resin and volatile oil, and sometimes employed to destroy proud flesh, or to cleanse old ulcers. Its action on the uterus is well-marked; it reproduces the catamenia when they have ceased on account of atony of the organ. It has also been employed in metrorrhagia, leucorrhea, &c. Here the powdered secale cornutum is generally preferred to it; especially in the last-named cases. Powder, twelve to sixteen grains in bolus or pills; infusion, half a drachm to a drachm for ptisan. Externally: four parts of cerate, and three parts of powdered savine, used to dress old ulcers. Pulverulent conserve: 40 to 120 grains in bolus or pills.

SACCHAROMALT (Blondeau): a mixture made with two pounds of sugar, five drachms and twenty-four grains of the bicarbonate of soda, and a sufficient quantity of lake carmine to color it. Used in the same cases as the lozenges of Darcet.

SACCHAROL OF THE CITRATE OF IRON (Beral, Pharmacien): eleven drachms of powdered white sugar, one drachm of the liquid citrate of the peroxide of iron, mixed together, and dried on the stove: afterwards powdered, and aromatised with a few drops (five or six) of the oleo-saccharate of lemon. Mode of exhibition, one to two drachms, two or three times a day as a tonic.

SACCHARUM, ALBUMINOUS (Mondiere); two pints of common water, the whites of six eggs (very fresh), carefully beaten together, and strained, and then three ounces of simple syrup, and four drachms of orange-flower water added. Mode of exhibition, three or four bottles of this mixture in the four and twenty hours for persons affected with dysentery; half the quantity for children.

SACCHARURES; sugar charged with medicinal principles extracted from plants by means of alcohol or ether.

SAFFRON (stigmata); powder, ten to thirty grains in bolus or pills, or by the endermic method; infusion, thirty to fifty grains to a quart of boiling water; syrup, half an ounce to an ounce, to sweeten potions, juleps, &c., tincture, thirty to sixty drops in an appropriate menstruum. The tonic and stimulant properties of saffron have caused it to be regarded as a condiment by the inhabitants of Southern Europe and of Asia. Its action, which is quite special and sedative on the uterus, renders it proper to combat the lumbar pains which precede, or sometimes accompanying menstruation. Finally, some practitioners employ it as an antispasmodic in hysteria, epilepsy, hypochondriasis, &c. *⁎* Saffron enters into the composition of the compound wine of opium, and many officinal and magistral preparations.

SAFFRON OF MARS, APERIENT: see subcarbonate of iron.

SAFFRON OF MARS, ASTRINGENT: see tritoxide of iron.

SAGAPENUM: a gum resin very rarely used, which possesses the properties of gum ammoniacum.

SAGO, SALEP: fecula employed as emollient and analeptic, in the dose of from one to two tablespoonsful to a cup of water, milk, or soup. The fecula of potatoes and tapioca, which are endowed with the same properties, are employed in the same dose, and in the same manner.

SALICINE: the active principle of willow-bark, employed as a succedaneum of the sulphate of quinine, in the dose of from four to twelve grains and more, two or three times a day, in the form of bolus or pills, or by the endermic method.

SARSAPARILLA: by long digestion, one to two ounces to a quart of water; simple syrup, one to three ounces to sweeten ptisans, apozemata, &c.; compound syrup, to which is sometimes added from eight to twelve grains of the deuto-chloruret of mercury to the pint of syrup, one or two table-spoonsful daily. Extract, or powder, rarely half a drachm to two drachms in bolus or pills. A stimulant, employed as a sudorific in the treatment of constitutional venereal affections, in chronic rheumatism, diseases of the skin, &c.

SARSAPARILLA, IODURETTED. see iodurretted decoction of sarsaparilla.

SANGUIS DRACONIS: powder, ten to forty grains in bolus or pills. An astringent very rarely employed.

SAPONARIA (LEAVES AND ROOT): infusion (leaves), one to three drachms to a quart of water; decoction (root), half an ounce to an ounce to a quart of water, extract (of the leaves), half a drachm to two drachms in bolus or pills Tonic and gentle diaphoretic, employed in cutaneous, and rheumatic affections, &c.

SASSAFRAS. infusion, two to four drachms to a quart of boiling water; general stimulant and diaphoretic, commonly employed with guaiacum, sarsaparilla, and smilax china.

SAGE: infusion, one to three drachms to a quart of water; distilled water, one to three ounces as the vehicle of a potion or mixture; essential oil, one to five drops on a little sugar. Stimulant, tonic, and diaphoretic, used in the treatment of the last stage of chronic catarrhs, in obstinate diarrhea, spasmodic vomiting, &c. It has also been used in the form of gargle in chronic angina, &c.

SOAP, ACETIC ETHEREAL (Pellotan): one ounce of scraped medicinal soap, dissolved in a water-bath in eight ounces of acetic ether. Mode of exhibition—one to two drachms in frictions, against rheumatic pains.

No. 290 **SUMMARY.** April 12.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES—MORBID AND HEALTHY.

By Dr. Knox, F.R.S.E., F.R.C.S.E.,

Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

LECTURE II.

All anatomists know that there exist several differences in the skeleton, the chief of which, no doubt, have a reference to the pelvis. But other bones differ perhaps as widely as do those of the pelvis; but such differences, leading to no direct practical results, generally pass either altogether unnoticed, or with but a passing remark. I shall speak of them in this order: the female skeleton is unquestionably generally smaller and feebler, but it is said that the skeleton of the head (the teeth included) is heavier when compared with the other bones or with the rest of the skeleton than in man.

It has been said that the cranium is larger in proportion to the face than in man; whilst all the osseous sinuses in and about the head are smaller. The skeleton of the thorax is evidently shorter in woman than in man; it is differently formed. The waist, or most contracted part of the body, is quite differently placed than in man, being much higher up; the distance between the last rib and the crest of the ilium, is much greater in woman. I speak, of course, of the well formed woman, for there are women made like men, and men made like women, and there are a great many persons who, of course, do not know this simple fact.

Now this difference in the form of the skeleton, as regards the lumbar region, produces corresponding changes in the arrangement of the lumbar and abdominal muscles; the loins are proportionally broader in woman than in man, and the triangular space between the latissimus dorsi muscle and the posterior margin of the external oblique is naturally wider and larger; the quadratus lumborum is longer, and a posterior free margin may easily be found for the internal oblique muscle, which in man is most frequently so short and ill defined, so difficult, in fact, to be dissected, that many anatomists have doubted its existence.

The cartilaginous prolongations of the ribs present differences; they are said to be longer than those in man proportionally to the ribs themselves; the angle formed by the running up of the seventh, eighth, and ninth, to the sternum and to each other, is more acute; the ribs themselves seem to be stronger and broader in man; the last rib is generally very small in woman. The sacro-vertebral angle is more acute in woman; the diameters of the pelvis larger in every way. I mention these matters here but in a general way, seeing that they belong rather to the minute examination of the pelvic cavity in woman—a subject of much more physiological and practical interest than had, I imagine, been ever supposed before the publication of my Essay on the Varieties of the Human Pelvis. Continuing, therefore, the mere enumeration of the peculiarities observable in the female skeleton, and the differences called sexual, we find that these increased diameters of the pelvis originate other peculiarities, —such as a shorter but thicker cartilaginous junction of the pubic bones; an arch of the pubis instead of an *angle*, as in man. The sexual differences of the sacrum have been much disputed; nevertheless, the assemblage of bones termed sacral vertebræ may be said to be, on the whole, broader above and narrower below than in man, shorter, also, and perhaps upon the whole more curved. I shall consider the point more carefully when speaking of the sacrum.

The greater distance between the cotyloid cavities alters the direction of the femurs, giving to those bones a greater obliquity than in man; this again changes somewhat the axis of the bones of the legs (tibiæ and fibulæ), and is perhaps connected with a peculiar form of foot, in which the arch is better marked, and the whole structure more finely formed than in man. The extremities are shorter, generally, that is, proportionally; so also are the hands and feet. In man, the foot ought to measure the one-sixth part of his whole height; in woman, seven feet and a quarter (taking her own foot as the standard) are required to give her height. Hence, arise numberless beauties connected with both forms associated in our minds with the respective and individual character of the sexes; if the foot of the male be much under the one-sixth part of his height, the circumstance will give to his whole appearance an effeminate cast; his walk will appear (whether it be so or not) unsteady, vacillating and tottering, like a column without a pediment; such incongruities never, so far as we have been able to observe, occur in the ancient Greek Statues, those divine models (for they really are so) of human form. On the other hand, if a woman's foot exceed the one-seventh part of her height, this accident will give to her whole demeanour and walk a masculine character, which scarcely any artifice can subdue or soften. We say of such a person that the tread is masculine, coarse, and too firm; the eye skilled and chastened in the doctrine of human proportions, detects it almost immediately, that is, if it really exceed considerably the due proportion, for very slight deviations from the standard will naturally escape observation. But to enquire into the reasons why such and such forms, male and female, should affect the mind as beautiful or the reverse, and how it was that the ancient Greek sculptors having discovered all this (as appears to me), and yet kept it secret from the rest of the world, thus creating, as it were, forms strictly human, and yet of acknowledged transcendant beauty; and how modern artists and anatomists have mistaken all this, and published and spoken respecting the antique, things, at once contradictory and absurd; to digress, I repeat on this point would lead to the exposition of the "theory of beauty and proportions," followed, as I conceive, by the ancient artists, and hitherto undiscovered by the moderns. This will fall in better in a subsequent part of this course, and in two or three special lectures. For after all, to discuss a "theory of beauty in human form and proportions" whilst discussing the anatomy and figure of the human skeleton, were peculiarly and altogether incongruous; nay even ludicrous, when we recollect that the artists who chiselled these wonderful statues, immortal works let us rather call them, of unsurpassed and of unequalled beauty, excepting always by nature herself, never saw a human skeleton, and would perhaps have been frightened and alarmed ever to have touched one, far more to have placed such a repulsive object in their *studio*; artists, whose whole ideas of art were diametrically opposed to the casual excitement in the mind of the spectator of the possible existence within that glorious frame of an unseemly emblem of frail mortality; to other races, and especially to the Saxon, they left the glorious discovery of there being "beauty in a skeleton!" A beautiful skeleton! With them originated, no doubt, the frightful "memento mori" and other abominations in art called sepulchral monuments and effigies, where the effects of putrefaction are represented as those of death and mistaken for them.

These remarks, as coming from an anatomist will I know surprise many, and more especially Mr. Haydon and the anatomical school of artists; but I have long, very long, reflected on these and similar points, and my opinions, instead of losing or altering, have become more permanently fixed by deep and continued reflexion, nor was I aware that in this view I had the support of a man of the very highest taste and knowledge; taste in the fine arts and knowledge of the anatomy of the human frame. I allude to Mr. John Bell, whose opinions I read only a few days ago in his "Observations on Italy." I know there are, and must be many who have adopted different views, and believing them to be, as they no doubt are, instinctive, are compelled to think them correct. To these persons I beg leave simply to apply this remark; to thousands, nay to millions, the Norwegian airs of "Rule Britannia," the "Duke of York's March," and "God Save the Queen," appear to be musical, they fancy them even grand and beautiful—but what is passing strange, they really imagine them to contain a good deal of music in their composition. Now, those having really a musical ear, and who feel that the frightful noise made by an "orchestra and the whole strength of the house," in performing, so they call it, one of these "coarsest of all succession of simple sounds," (for airs we can scarcely call them) is, in point of fact, not music, are not bound to alter their opinions, merely because a race, destitute as a race of a musical ear, fancy such things to be musical; neither is there a necessity for these possessing a sound eye and taste for beauty in high art, being obliged to give way to the opinions of those not gifted with such feelings. Let us return from this digression to what is beautiful, namely, the human form as chiselled by the ancient

Greeks, to that which is not beautiful, the human skeleton.*

Even in skeletons of equal height there are perceptible differences in the greater delicacy of the female bones compared with the male; they are less strongly marked, generally much more slender, of a finer grain, and perhaps whiter when prepared by bleaching.

In the cranium, the superciliary ridges are almost universally less prominent. The frontal sinuses less capacious, the bones of the face smaller, jaws of diminished bulk, teeth smaller.

On the authority of Sœmmering I may state, that the bodies of the vertebræ are more elevated, the transverse processes more strongly curved backwards, the vertebral grooves deeper, the spinous processes more slender, shorter, and more imbricated, and the substance of the bodies of the vertebræ denser than in man. The ribs are thinner and less arched, their edges sharper; the manubrium of the sternum proportionally broader, the lumbar vertebræ deeper, the sacrum broader (superiorly); and more concave, and shorter; the coccygeal bones more mobile and narrower. Of the ossa innominata I need not speak here, as the pelvis, with all its varieties and several differences, will fall to be considered more minutely afterwards. The clavicles are straighter in woman; the scapulæ thinner, flatter, and sharper at the angles; the thigh bones more arched, and the inner condyle larger.

Individual Differences in the Skeleton.

Few facts have been collected in respect to individual differences in the skeleton; few facts of any consequence. The bones of giants and of dwarfs have been measured, but no conclusions drawn from such measurements useful in so far as I know, to anatomical or physiological science. There is a closer resemblance between the giant and the dwarf than has been imagined; the dwarf often shows giant features in the face, hands, and limbs. Nature resists successfully the tendency to extend the race of giants and dwarfs by arresting their propagation; the family in fact dies out, and so disappears. A couple of hundred years ago it was easy to exhibit the bones of an elephant for the veritable remains of Goliah, and a fossil salamander for the *homo diluvii testis*; but such coarse impostures would scarcely succeed now, even with the well dressed vulgar, who know better and doubt all these fables. Yet great individual differences exist, of which the more remarkable will be noticed in speaking of the individual parts of the skeleton, the cranium, spinal column, &c.

Can the form of the skeleton be influenced temporarily or individually by the mode of life, habits, clothing, &c.? and can such alterations in the form of the skeleton be perpetuated or transmitted to posterity?

A very general and a very ancient belief exists, that by artificial pressure the form of the human bones may be permanently altered—so far, at least, as regards the individual—and the cranium in certain American tribes, and the altered form of the chest in civilized woman, are the often cited proofs, if proofs they can be called, of the efficiency in the assigned causes for the production of the supposed effects. Now to me there does not seem to be a word of truth in all this, and still less in the theory which no doubt some would call "venerable from its antiquity"—the theory of Hippocrates†—that a race of people inhabiting the shores of the Black Sea had been so long in the habit of compressing and flattening the heads of their children that the crania so flattened in childhood not only remained so in after-life, but that the form thus artificially produced in the individual came to be perpetual in the race—extended, in fact, by propagation. This is precisely, or very nearly, the same story, reported by Hippocrates two thousand five hundred years ago, as is now told of the Cherokee Indians and Caribs, proving the old adage "how little there is new under the sun." These questions, perhaps, merit a more lengthened enquiry than I can venture to give them at this part of the course; let me examine them in so far as regards the feet, the hands, the chest, the spine, and the head.

And first, as regards the feet. For about four thousand years, the Chinese have endeavoured to alter in the very slightest degree the form, the size, and the shape of the foot of woman, and they have entirely failed in their great object, which must have been, if possible, to possess a race of women whose feet were *naturally* and congenitally—that is, from birth—unnaturally small; their failure to effect this has been total and complete. True, they can compress and torture the individual woman; they can bend the toes under the foot; destroy and waste the muscles of the leg; shorten the foot by some inches, and mar fair Nature's proportions;—still all this is confined to the *individual woman*; never is the deformity transmitted to the offspring; never is it found to be *congenital* or hereditary. This fact—this great experiment—should settle with all reasonable persons the second question; should set aside the "*venerable*" theory of Hippocrates, as to the possibility of an *accidental* deformity becoming hereditary. Dr. Pritchard's story of the short-legged sheep of some American state is, I fear, a fable.

There is a deformity of foot of all others, perhaps, the most common; I mean plaiting of the toes. Generally it is the great toe which is bent outwards towards the second, sometimes over and sometimes under it; this ends in a partial dislocation of the first phalanx from off the metacarpal bone, the large rounded end of which coming now to project is mistaken by the surgeon for a bunion; the ligaments give way; some new bursæ occasionally form, but not always, and a good deal of pain is often endured. A London surgeon who has seen, perhaps, but few naked feet, has spun up from the very slightest materials a fine theory as to the cause or causes of this deformity; he ascribes it to *tight shoes*,—but let him visit Glasgow—let him visit Scotland, where thousands and thousands walk the pavement and the roads, and who never all their lives wore a shoe, short or long, tight or easy, and a single day will convince him that his theory has not the slightest foundation in truth. For here we find the plaited semi-dislocated great toe in all ages in both sexes, young and old, rich and poor. The *tendency*, in fact, to this deformity is a congenital tendency, and the partial dislocation comes on sooner or later, according to the *strength* of the *tendency* or *disposition*. The inner or tibial side of the foot is in the very young slightly concave; in middle life it ought to be straight; as we advance in life there is a strong disposition for the great toe to lean outwards—to leave the articular surface of the metatarsal bone and to bend outwards over or under the second. But this change in the direction of the inner margin of the foot is not necessarily the result of age, since it does not always happen; and as to what has been said about the production of this same deformity by tight shoes, long standing, weight of the body in fat persons, &c. &c., I may say, in a word, that such theories are merely the conjectures of ingenious men, endeavouring to explain phenomena which they do not comprehend from their not having sufficiently enquired into them.

By this time you will no doubt have observed that I am altogether opposed to the notion, that by mechanical means, generally permanent alteration of the skeleton can be effected; that such, when they are efficient, as in the case of the Chinese female foot, are limited merely to the individual; that the ordinary deformities observed in the European foot do not arise from any mechanical contrivances, but are the result of congenital predisposition; that the latter may be, and often are, hereditary; the former never.

I should next proceed with the enumeration of the effects of mechanical pressure in permanently altering the form of the hand, but no such effects have been recorded.

Lastly, the effects imagined to be produced on the spinal column by the immoderate use of the right hand, nursing, playing on the piano, drawing, writing, standing too long on one foot, tight corsets, &c.; and the effects which tight corsets are supposed to have on the form of the female chest ought next to be examined; but the doing so in this lecture would detract much from the interest of what I shall have to say when speaking of the anatomy and physiology of these particular divisions of the skeleton; and I shall, therefore, reserve the views I have adopted on these matters, until I arrive at the particular history of the spine and chest: much ingenious twaddle and declamation we shall find has been laid before the public occasionally in very ostentatious folios; theories—mechanical theories—easily refutable have succeeded each other like phantasmagoric figures; but the supposed effects of pressure on the form of the human skull, I admit to be a subject beset with difficulties, regarding which, as so frequently happens in physiology, "much may be said on both sides."

---

* Professors of pictorial anatomy are bound to say something in favour of the snug but excessively paltry jobs they enjoy. A lecture on Pictorial Anatomy (Pictorial Anatomy!) by a Professor who actually did not know that the great toe stands apart from the others, until a young artist pointed it out to him, will fall to be reviewed more appropriately in a future lecture; it is a rich morsel, culled from Dickens, Reynolds, Bulwer, &c.

† De aere, aquis et locis.

A COURSE OF TWELVE LECTURES ON SKIN DISEASES

By D. J. CORRIGAN, M.D., Physician to the Whitworth, Hardwick and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

Having now finished the subject of fevers, including those really and truly so called, as well as that disease to which our Continental brethren have erroneously given the name, we shall pass at once to the only remaining division of our course, and take up the subject of skin diseases. On this occasion I shall adhere to the method I have followed on preceding years, of not laying before you any information but such as I conceive you would not be likely to find in systematic works on the subject. At the same time I shall endeavour to clear away some of the difficulties which surround the student when entering upon the study of this class of diseases, which are unjustly said to be more difficult to understand than any other maladies to which "*flesh is heir.*" Here, *en passant*, I would beg to lay down one rule for your guidance in the study of skin diseases; that is, never to pronounce an opinion upon any cutaneous affection, from the mere fact of seeing it at any one particular period of its occurrence. To exemplify what I mean: in erysipelas, which is *purely* an inflammation of the skin, extending occasionally to the tissues underneath, and which sometimes forms vesications on the affected surface, you would not be justified in your opinion, if you classed it among the "bullæ" from the mere fact of having seen the disease when these vesications were appearing. The bullæ in this skin disease are merely an incident, they are not an essential feature in it; the only thing which constitutes the disease in question being an inflammation of the skin attended with certain other symptoms. These are the essence of it, the "*sine qua non*," without which it cannot or could not exist; wanting these it would be something else, but not erysipelas. Another illustration:—both small pox and measles appear at first in the same form, namely, as stigmata, which are nothing more than star-like clusters of congested cutaneous vessels. In small-pox, after some very short time, these stigmata change to papulæ, which become vesicular at the top and seated on hardened bases; these again lose their vesicular character, become pustular, and filled with a purulent fluid; while in measles, the stigmata which denote the disease never pass into any other change of form, but, after a few days continuance fade away. Therefore, how wrong would it not be, if called to the bedside of two patients presenting these stigmata, you were to pronounce a decided opinion upon both, and call them small-pox or measles, just as the case might be; and this, merely because you had seen them at a time when they presented the same appearance? Therefore I would again warn you never to pronounce an opinion on any skin disease merely from witnessing any one of its phases. Wait for some little time further, so as to allow of its future

changes (if any) being developed; and then you can confidently pronounce your diagnosis. This was the error into which Alibert fell, this it was that led astray him, an observer otherwise so accurate. On the present, as on former occasions, the system which I shall adopt will be that of Biet, it being, in my opinion, the most simple and that which will enable me to convey to you the clearest notion of skin disease. His system is divided into eight great classes; these again are divided into orders; and the latter into species or varieties of each order. In this lecture, which is merely prefatory to the subject, I shall content myself with laying down for you the classes themselves, and giving you an example of each of their orders without entering into the consideration of any of their varieties, my object in this lecture being, merely to give you such directions as will enable you to recognise the different classes of skin diseases which may present themselves to your notice. The division I am about to lay before you will, I trust, render the subject much more plain and intelligible, in place of making it intricate and difficult, as it might at first sight appear to do.

BIET'S ARRANGEMENT OF SKIN DISEASES, ADOPTED BY DR. CORRIGAN.

Classes.		Type of the class	
1. Exanthemata		Type of the class	Scarlatina.
2. Papulæ		" " "	Lichen.
3. Pustulæ	Varieties. Phlyzacia. Psydracia. Favi.	" " "	Variola.
4. Squamæ		" " "	Psoriasis.
5. Vesiculæ		" " "	Herpes.
6. Bullæ		" " "	Pemphigus.
7. Tuberculæ		" " "	Elephantiasis.
8. Maculæ		" " "	Ephelis.

Commencing with the Exanthemata, or eruptive diseases, we shall select scarlatina as a type of the class. In this disease, a diffused redness, attended with fever, appears all over the body, commencing on the face, and extending thence over the trunk and extremities; it continues out for a few days, and then disappears. We know nothing more of this eruption. Observation has enabled us to trace the signs which distinguish it from those accompanying other eruptive diseases: as to its further nature we are completely ignorant.

In scarlatina we have all the essentials of the exanthemata: redness and efflorescence of skin, attended by fever. In erysipelas, which is another of the same class, we have the essential characters of the exanthemata. In the latter disease there are sometimes added bullæ, which are merely *incidents*, not being at all peculiar to the disease. The second class is papulæ, or pimples, where the skin is sensibly rough to the touch. These papulæ sometimes become vesicular: they never form a scab, but invariably desquamate, or scale off. The most familiar example of this class is lichen, or red gum, appearing in children for two or three months after birth. It is well known to mothers, and must be familiar to such of you as have attended the practice of a lying-in hospital, or children's dispensary. It is a disease of little or no consequence, and generally proceeds from some derangement of the "primæ viæ" of these children in whom it appears—(Handing round some of Alibert's plates of the varieties of lichen, he said:)—"Here you have an opportunity of seeing its peculiar character. Pustulæ, or pustules, next claim our attention. Of pustules there are three varieties—the phlyzacious, the psydracious, and the favous. These three divisions of the class of pustules, in place of making the subject more complex and difficult, will, on the contrary, make it much more plain than it otherwise would be, if you merely pay attention to the characteristics of each variety. By means of these marks you can never in any case, be at a loss to know to what variety a pustule may belong, and this knowledge will simplify very much the succeeding treatment. Of the first or phlyzacious variety, small-pox is as good an example as we can take. Here the disease commences with a small protuberance, which is hard at the base and inflamed, and gives to the finger passed over it the sensation as if a grain of shot were imbedded in the skin. This protuberance becomes vesicular at the top; in a few days it loses this character, and the lymph becomes changed into pus. After some days longer, this pustule dries, scabs over, falls off, and leaves underneath a firm white cicatrix, indented with minute depressions. After having once healed, this pustule never is produced again, save by a re-application of the primary exciting cause. This will be important for you to recollect, as it forms an essential distinction between itself and the next variety, the psydracious. Of this variety, the best illustration that I can give you, is the disease which is commonly known under the name of *crusta lactea*, the *porrigo larvalis* of Bateman. It is not porrigo at all—it is impetigo. I am sure you all know the disease I speak of.

In this disease, the face becomes the seat of numerous flattish yellow pustules, these gradually spread all over it, the matter in them dries, and thus a scab is formed, which from the propinquity of each pustule one to the other, envelopes the features as in a mask (whence Bateman's name for it). Underneath this scab, matter still continues to be secreted, which gradually renders this coat of scab denser and more dense. *If you remove these scabs either by the application of ointment, or by any other means, you will find in the reddened and raw surface beneath, innumerable puncta, from which a clear limpid lymph is being discharged; this lymph being the secretion from the surface of the cellular tissue which previously formed the contents of the pustule, and having become dry, subsequently formed a scab.* This disease, notwithstanding its unsightly appearance, never leaves any deformity after it, for when it has been removed by appropriate means, the skin of the face quickly recovers its usual aspect and softness. The purulent matter here is formed in the same way as it would be, were a blister applied to any part of the body, and that the bullæ raised by the blister instead of being distended with serum, were filled with purulent matter. Whenever you find a pustular disease where the subcutaneous cellular tissue continues to secrete purulent matter—the pustules having been previously broken or the scabs removed—you will be quite correct in asserting such disease to be an example of the psydracious pustule. The favous pustule presents appearances so peculiar and characteristic as to entitle it to a much more lengthened notice, than we can afford it here. The next class is Squamæ or scales, where a portion of skin becomes scaly, changed in colour from its natural hue, and sometimes cleft or fissured. These scales desquamate or fall off from time to time, and are again renewed. The most familiar illustration of this is psoriasis or scaly tetter, in which the scales never rise above the level of the skin: this serves to distinguish it from some other scaly diseases, lepra for instance, from which however it should not be separated as both are identical. In these plates (sending them round) you may see the different appearances psoriasis presents in all its varieties, appearing on various portions of the body, the backs of the hands, forearms, face, ears, trunk, &c. Vesiculæ or vesicles come next. The character of a vesicle is as follows, first a papule appears, which in a day or two becomes filled with a clear lymph, this becomes turbid after some days longer, and if left to itself always ends in desquamation.

The most familiar form of this class is herpes, which you will find presenting the characters just mentioned whenever it appears on any part of the body. The upper lip is the most general site of its appearance, here it is frequently seen at the close of catarrhal fevers and slight colds, and you will frequently hear persons remark, "Oh, I shall soon get rid of my cold, now that it has broken out on my lips." The next class is Bullæ or "blebs;" of these pemphigus is the type. Its characters are the appearance of a round bleb on some part of the body, filled with a clear fluid, which, if left to nature, eventually becomes absorbed. You will have a tolerably correct idea of its appearance if you fancy a small blister applied to different parts of the body, which produces a number of small vesications. This cast, taken from nature (exhibiting the foot of a child affected with pemphigus), gives you the exact appearances which pemphigus presents. This disease is not one of very frequent occurrence. The next order Tuberculæ, typified by elephantiasis, presents the character of hard protuberances on different parts of the body. The class in this country does not present a single disease worth our attention or trouble. The eighth and last class is Maculæ or spots, the character of which is a discolouration of the skin, sometimes permanent. This discolouration may or may not be attended with disorganisation of the subcutaneous tissue. In this class are nævi, mother marks, spili or moles, ephelides, sunburns, freckles, &c. By recollecting the characters of these orders of skin diseases, you cannot fail after a little close study, to make yourselves masters of the varieties of each different order. By their help you will not fail to know scientifically and methodically many diseases which, conversant with hospital or dispensary practice, you knew before but by sight. By their help, with a little attention, you will easily recognise the class and order to which any cutaneous disease may belong. And when once you have this determined, you may reckon yourselves possessed of an amount of knowledge sufficiently minute for all practical purposes. To be sure, there are in each order sub-divisions or varieties, but in most instances these amount only to two or three, and to know these is very often of little or no practical importance. Before we proceed to examine the different varieties of skin diseases, allow me to call your attention to some plates, showing the difference between the psydracious and the phlyzacious pustules. I searched for them ineffectually at the commencement of the lecture to assist me in illustrating the difference between each variety. In this plate of Alibert's (handing it round) you can very well perceive the innumerable minute orifices from which—when the psydracious pustule is broken—the lymph continues to be discharged. Here (handing round another) you can see the scab which this lymph when changed into purulent matter, forms, and which completely covers the the features. In this drawing, admirably painted from a subject under my care, you have an example of the psydracious pustule before it has been broken or injured in any way. This is the disease which has been called "scald head." This is an error, for genuine scald head is a disease of extremely infrequent occurrence. In these other two fine drawings, you have additional examples of the phlyzacious pustule; one of these (handing it round) is a case of modified small-pox; this other is one of mentagra or sycosis. The differences which exist between both these forms of pustular eruption, I have detailed to you already. At our next meeting we shall proceed to examine practically—and I trust that in these lectures nothing will ever be delivered which will not have a practical bearing—the varieties of diseases which are comprehended in the various orders already mentioned.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

The prognosis, with regard to affections of the brain, is always dangerous in the extreme, and the opinion ought to be the more guarded the longer and more violent the disease has been. The treatment of inflammation of the membranes of the brain must be of a very active kind; in particular, blood-letting to syncope, should be resorted to. A sitting or erect posture, so as to check a disposition to determination of blood, is the most advisable position for the patient. Beside bleeding, there are other antiphlogistic means which must be adopted: the head must be shaved—and kept as cold as possible, by bladders of iced water; drastic purgatives should be also administered. Calomel and tartar emetic should be given, to keep down, the vascular action. Besides these remedies mercury should be used, as a sialogogue, especially in meningitis, and continued until the gums are fully affected. In chronic cases, blisters, near the affected part, should be applied, but these must not be ventured on in acute cases. Leeches and cupping should be employed wherever there is great pain. Sometimes paralysis exists, as an indication of the hemisphere to which counter irrita-

tion is to be applied. In your treatment of brain diseases, it will be necessary to guard against all excitement, both of mind and body, even for a long time after your patient's convalescence. If this precaution be attended to, and the general health of the patient be good, he may soon return to his ordinary occupations.

There are some particulars which ought to be noticed, in which acute hydrocephalus differs from the common brain inflammation. Hydrocephalus depends on inflammation of the membranes of the brain, particularly the central portion of the lining of the ventricles, or certain portions of the base of the brain,—as the *pons varolii*,—and the membranes covering them and of the base of the nerves; and in consequence of which, it exhibits a tendency to end speedily by serous effusion. The early symptoms are like those of arachnitis; you will find delirium, with heaviness and stupor, considerable uneasiness in the head, which soon becomes changed into actual pain, so intense as to produce screaming and convulsions. These symptoms end either in fatal coma, or partial paralysis. Acute hydrocephalus is confined chiefly to children and young persons, and is seen with greatest frequency in those whose intellectual powers are beyond their physical strength. What does this depend on? On an increased flow of blood to the head, from inordinate vigor of the cerebral circulation: another cause to which it is ascribed is derangement of the abdominal viscera; but whether this is cause or effect is not always certain; when dependent on the latter cause, the symptoms which have been observed, in its *first stage*, are, pain in the head, intolerance of light and sound, and quickness of pulse. In the second stage, the pulse becomes slower and irregular, and the pupil, instead of being contracted, as in the first stage, becomes dilated, and there may be strabismus, or convulsions coming on, from time to time, and alternating with a state of stupor. The child tosses its head and arms to and fro, gnashes its teeth, and the mouth becomes so firmly closed that nothing short almost of actual violence will suffice to open it. The last stage is marked by complete or incomplete paralysis, in which the functions of the brain are always implicated; the pulse becomes quick and thready, and the stupor complete. In this stage, a curious phenomenon is occasionally observed—one side being paralysed, and the other convulsed. This strange effect must be owing to something beyond mere effusion. The disease generally proves fatal in from one to twenty days, and such is the extraordinary rapidity with which death occasionally sets in, that in some cases of this disease you can scarcely imagine that inflammation has had time to make its appearance. These cases are properly called determination of blood, or blood-stroke, according to the Germans; and closely resemble apoplexy, in the suddenness of their fatality, and in being accompanied by effusion of serum. In 2-5ths of such cases, the disease is fatal; still, recovery has taken place in the very worst cases, and I myself have seen two or three such instances. In one case, a child was affected with all the symptoms I have described. I left it, despairing of its recovery; twelve months afterwards I was astonished to hear from the father that the child was well and thriving.

In these cases, the quantity of serous fluid found in the head is very remarkable, amounting, at times, to four, five, or eight fluid ounces of limpid liquid, with which are occasionally blended coagulated lymph. There have been found, in some instances, tubercles in the meninges of the brain, which appear to be the great predisposing cause of hydrocephalus. Softening of the brain, is also, occasionally met with.

Now, the treatment of this form of inflammation may, in the first instance, *and in it alone*, be blood-letting, and more than one bleeding can be seldom attempted, the loss of blood weakening the patient without reducing the inflammation. Leeching and cupping the head and abdomen have been found more useful than any other modes of depletion. The chief reliance is to be placed in active purgative medicine, especially hydrogogues, in combination with large doses of calomel. These are to be repeated till serous evacuations are produced. This exhibition of purgatives is a very powerful means of reducing the heart's action. With their employment, cold to the head should likewise be used, whenever its heat is much increased. The calomel may be given alternately with tincture of cantharides; and the latter must be administered in frequently repeated doses, till strangury is produced. The dose of the tincture, of course, will vary with the age of the child. From three to ten drops may be given to a child of five or six years old. Opium has been found useful in the last stages of hydrocephalus. There are some morbid affections, arising from determination of blood and congestion to the head, produced by improper food, and other debilitating circumstances, which resemble these cerebral diseases, and require to be noticed here. In children a disease occurs which seems to be analogous to hydrocephalus. The child, in such cases, lies in a partially comatose state, with the eyes half shut, and from this cause the latter organs very often become inflamed; the pulse is quick and very weak, and the face is very often flushed. The pulse here presents a peculiar jerking action, which, with that of all the superficial arteries, is distinctly visible. There is also great pallidity of the surface, and the feet are commonly cold, and any heat that may exist is centred in the head. The pulse is very much altered by change of posture. There are some symptoms like those of adult arachnitis, arising from similar causes. Females who have become anœmose from hæmorrhage, or any other debilitating cause, frequently complain of noises in the head, flashes of light before the eyes, giddiness, headache, and throbbing in the head, with intolerance of light and sound. The means of cure generally adopted in this train of symptoms are depletive measures, under which the patient becomes worse. You must learn to distinguish this seeming, from real inflammation, and you may do so by the pallidity of the surface, the jerking and compressible character of the pulse; and by the *bruit de soufflet*, which you hear both in the veins and arteries, telling you plainly that the disease originates in some cause which robs the circulating vessels of a portion of their contents.

You will find position to furnish a very useful diagnostic between both affections. In the latter, you invariably find that a horizontal posture gives the most relief, while in arachnitis the patient cannot endure this, but endeavours to sit upright. Finally, the disease simulating arachnitis may be relieved by opium and other narcotics, or by the exhibition of stimulants, means which would not fail to aggravate the inflammatory affection. The pathological peculiarity of the cerebral circulation will partly explain this. The great reason why the head is so much affected in these exceedingly weak and feeble females, I believe to be, that where the power of the heart and the quantity of its blood have been much reduced, the vacuum and loss of power which are felt, originate in the heart, travel onward to the brain, setting up within it, a degree of asthenic irritation which produces the phenomena in question. The production of this irritation depends upon the vessels of the brain not accommodating themselves to the lessened current which passes through them. They still preserve their tonicity and power of contraction; and a very trifling acquaintance with physics will teach us that under such circumstances, the velocity of the circulation must be increased; and that the contractility or quantity of contractile power, which before was barely sufficient to propel the healthy current of blood with a due degree of rapidity, is now expended in making that fluid travel with increased velocity through the vessels of the brain.

The treatment of this latter affection must be sedative and tonic, the object being to calm the heart's irritability, while you increase its muscular power. To the former end you may employ prussic acid, hyoscyamus, or digitalis. Opium appears to answer best in the generality of cases. Great care should be taken to avoid aggravating the heart's action by excessive exertion,—such as sudden changes of posture, &c. To restore the tonicity of the heart—the principal object to be kept in view—we must endeavour to strengthen the system as much as possible by a nutritious diet, and to excite the action of the capillaries by the application of cold to the head, and warmth to the extremities. Where the pain in the head is so severe as to prevent rest, local depletion may be employed, with sedatives to quiet the action of the heart, and it may be often necessary to combine both these means with stimulants to increase and rally the power of the heart. Sometimes symptoms of an opposite nature arise in anæmic children, and young females who have lost a great quantity of blood; they become heavy, and particularly comatose, or the pupils become dilated, and the patient sometimes become cataleptic, retaining neither power nor consciousness. These symptoms may set in without any heat of head, or any increase of pulsation in the arteries, or any other indication of increased vascular action. Nevertheless the patient may die. In this state the sinuses are found filled with fibrine and coagulated blood, the veins are distended and obstructed partly with fluid blood, partly with coagula. In some cases there is coma without reaction, but in other cases there is reaction, more or less heat, increased pain, dilated pupils, and convulsions. After death these cases exhibit some slight signs of inflammatory action, and increased vascularity, not confined to the veins alone, but extending even to the membranes.

Besides the clots in the sinuses, there will be observed effusions of blood about the veins, showing the amount of distension and obstruction to which they were subjected. I believe those cases have their origin in congestion, arising from the quantity of blood in the head being too great for the force of the circulation, and hence, while the action of the heart is weak in anœmic subjects, the patients often complain of a dull heavy pain in the head, instead of the symptoms of excitement I have mentioned. The explanation of this seems to be that the propelling power of the heart does not act upon the whole of the blood in the brain, and that it is too weak to propel the disproportionate mass of blood through the latter organ. This view is confirmed by the effect of antiphlogistic remedies. The treatment here should not be purely antiphlogistic. It may be useful to apply leeches to the head, or dry cupping, to the extremities. The great thing is to draw blood to the extremities, and to increase the vigour of the circulation by diffusible stimulants. There is generally great advantage derived, in congestive headache, from the use of stimulants. It is a question whether, in these cases, heat to the head, and the action of mercury might not be useful. We have next to consider apoplexy and palsy, which may be taken together; apoplexy first, and palsy as its result. Apoplexy mostly makes its appearance suddenly as a fit, causing a loss of consciousness feeling, and voluntary motion, or what expresses the same thing, an interruption of the functions of the brain. In some instances, the interruption is complete,—in other cases partial, and then it may not be apoplexy, but paralysis affecting the motor and sensitive powers. It arises from various causes: from pressure, as when a clot of blood is effused into the brain, interrupting its functions, or causing disorganization: but it arises more generally from the former than the latter cause. Sometimes it is produced by shocks that injure the nervous function in some way that does not admit of easy explanation; poisons likewise cause it. Apoplexy may occur as the result of inflammation of the brain, its meninges, or medullary portion, just as we find congestion and hæmorrhage occurring in the various viscera, in connection with inflammation, as its first stage, or as its sequel; where this is the case, the apoplectic stroke will be preceded by symptoms of inflammation; but it often happens that these are very obscure, and indistinguishable from other symptoms that sometimes precede it. The premonitory symptoms, in cases of apoplexy, are: heaviness, somnolency, pain and throbbing in the head, which are always considerably increased by stooping or lying. The temporal arteries may be seen very much distended, and the eyes are red, suffused, and heavy looking. There is generally weakness of the intellectual faculties; loss of memory, apathy, lethargy and sluggishness; or there may be a kind of moral weakness not natural to the individual, a disposi-

tion to cry, or be easily excited at slight things. Sometimes there is an increase of the animal and moral functions, at the same time that there is a defect of intellect and of memory, both in speaking and writing. Occasionally, before the apoplexy occurs, the motor nerves lose their power, and articulation is impeded, becoming indistinct, like that of a drunken man. There is often an inability to close the eyelids, with a twitching of the muscles of the face, effects accompanied by torpor or numbness, which, in some cases, affects but a limb or part of a limb, while, again, it may extend over one side. There is generally more or less weakness and oppression of the system with indisposition to exertion, and a tendency to fatigue, faintness, and syncope. Then comes the apoplectic stroke, or fit, often induced by sudden exertion of the body, or trivial excitement of the mind. The mere effect of stooping will bring it on, and the excitement caused by a full meal will produce a similar result. Most commonly it comes on at midnight—the period at which gout is most apt to occur. The manner in which the fit may occur varies: in what is called the thundering apoplexy, a person is struck down by a tremendous shock, as if by a blow of an axe. In this case the person may be walking, when suddenly his face is observed to become very pale and livid, convulsions occur, his breathing becomes stertorous, and death may take place in a few hours, or even in a few minutes. When the stroke is not immediately fatal, a state of insensibility with stertorous breathing is produced; the eyes are open, or only half closed, the pupils dilated, and sometimes contracted—the dilatation from loss of power, and the contraction from irritation; than the latter there can be no worse sign; sometimes one pupil is contracted, and another dilated. The pulse in these cases is sometimes slow and full, and often hard. This is reduced sometimes as low as forty beats in a minute, and is then called, a labouring pulse. Sometimes it is irregular, intermitting, and frequent, a state of the arterial system which is only met with in the *thundering cases* of apoplexy. The symptoms I have described are accompanied by a state of syncope, the patients will not answer questions, nor do they exhibit any sign of feeling in being pinched. In extreme cases, the stools and urine are passed involuntarily. Swallowing is difficult, and sometimes the urine and fæces are retained. The body is warm, and the head hot. The coma produced by apoplexy terminates invariably at a period varying from two to three days, in death, or complete or partial consciousness. Complete consciousness takes place much sooner, when it is partial, it may take place in three days. In some cases, paralysis is a consequence of apoplexy: the tongue protrudes to the paralysed side, and hemiplegia and paraplegia are often the results of the apoplectic shock.

THE STRUCTURE AND FUNCTIONS OF THE BRAIN WITH NEW VIEWS ON THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine.

Formerly Physician to the Bicetre and Salpetrière Asylums; Author of the "Traité Médico-Philosophique sur l'Aliénation mentale Médicine Clinique," "Nosographie Philosophique," &c., &c. Translated with Notes illustrative of some important doctrines in Physiology, Phrenology and Moral Education

By Dr. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c

EXTACY.

"The word *extacy*, says Andral, pourtrays in some degree the physiognomy of this disease; for what do we observe in this state? Under the dominion of one idea, all the intellectual faculties of the individual are absorbed in it, and it would seem as if the nervous influence, as far as regards its development over all the parts of the body, had undergone profound modifications."

The exaggeration of religious ideas has especial influence in giving rise to extacy.

"It is not alone the intelligence that is modified in this state, all the other functions of the life of relation and nutrition, are equally affected."

In order to have a perfect idea of extacy, we must read its definition, or, rather, its account, by Saint Theresa:—

"At first the attention is concentrated by the reading of some work of piety, this is followed by a profound contemplation, or sort of quietude, accompanied by a feeling of intoxicating joy. In the third degree, it is marked by the most vivid, the most pure enjoyment; the effusion of the most ardent love; a species of exaltation bordering on madness. In the fourth degree, there is a sort of sinking, or complete swooning, the extatic delight has attained its utmost height of vividness and power; the breathing is suspended—the limbs are immoveable—the eyes involuntarily closed—the power of speech is gone—the use of the senses is suspended—while all the moral faculties are raised as it were to their utmost point of energy, or, rather seem to contract a sort of intimate union with the ideal object of those fantastic illusions. The feeling of ravishment is then so impetuous, that one feels as if transported to the clouds dwelling in heaven, and enjoying a foretaste of extreme felicity; the breathing is stopped—the pulse not to be felt—the limbs are rigid—the first position and attitude remain unaltered, and the state is one of apparent death. This is the moment of the outpourings of the most ardent love—of solemn promises—of heroic resolves."—*Phil. Nosog. Philos*, t. xi. p. 130.

"The extatics, whose names are recorded, have become celebrated from their love of poetry, the fine arts, philosophy, the sciences, religion, morality, or of the contemplation of God and nature. Extacy, like all the great passions, and the exaltations of the intellectual and moral faculties, is usually of short duration. It is favoured by solitude, silence, and that contemplation, which, by concentrating the attention on one object, has the effect of closing the senses to external impressions. Archimedes was in that state, when absorbed in the solution of a geometrical problem, he was dead, as Plutarch relates, to all natural wants, and deaf to the tumult of the foreign enemy that were sacking the city. Plato says, that Socrates remained 24 hours on the same spot, immoveable, exposed to the heat of a burning sun, and absorbed wholly in the depth of intuition.

"In the state of extacy, the visceral and cutaneous sensibility, and even the senses themselves, are completely abolished. In an extatic rapture, Paul the apostle believed himself to be transported into heaven, and had so little consciousness of bodily existence, that he did not know whether his body remained on earth, or was caught up to heaven also. There he heard things miraculous and ineffable, which it is not given to man to relate, or even to comprehend." Hallucinations of every kind may arise, and extatics describe their state with such energy and conviction, that it is impossible to refuse belief of their sensations. As regards the movements, the greatest variety of disorder may occur between the extremes of convulsion and paralysis.

The disturbances in the life of nutrition are quite as remarkable as those of the life of relation. Individuals in the extatic state may live without food for a certain time, just as persons labouring under fever do. The circulation becomes slow, the skin cold, and the secretions no longer take place with regularity.

"The state of ecstacy may exert an influence on the production of a certain number of diseases. Neuralgia, and various congestions may be ranked among the number. Like anger, or fright, extacy produces paleness in some persons, flushing in others.

"Extacy may be followed by the cure of certain diseases; it produces a profound perturbation of the nervous system, comparable to a certain extent with the action of narcotics. Extatics have even been known to effect the cure of their own diseases, by the power of the will; and I do not object to the admission, that the power of extacy may cure not only neuralgia, but even diseases that have laid deep hold on the system, such for instance as those ranked under the head of hyperæmia.

"It is, however, to be remarked that such cases have become more and more rare in the 19th century, while on the other hand, they abound in the dark ages, when it was easy to impose on public ignorance and credulity.

"The extatic state is sporadic, and often epidemic. The annals of science furnish three or four cases of epidemic extacy; in both, its forms are the same. The late Bertrand wrote a very good work on extacy. It contains some of the most curious cases that have astonished the world from the fabulous times of the mythology down to the period at which he wrote.

M. Calmeil enters also into some important considerations in his article on the subject, in the Dictionnaire de Medecine. "We cannot," says he, "refuse to admit different kinds of extacy. Those persons who are represented as *petrified*, merely from fright, or unexpected pain, do they not experience an attack of some peculiar extacy? These lovers spoken of by H. de Heers, and other writers, who could only be restored, to an active life, by shouting into their ears as loudly as possible, that no further obstacle should be thrown in the way of their happiness, were they not under the influence of some extatic passion? M. Dessessarts mentions a young Englishman who lost by starts the use of all his senses, and who could solve during the extatic crisis, mathematical problems of which he had not thought before."

"Mystical extacy is observed chiefly in fervent persons, given to fasting and prayer, habituated to want of sleep, and to a purely ascetic and contemplative life; and this is the case to such a degree, that one may by means of certain practices, acquire a nervous affection which may incontestably impair the reason. In this way the frequency of extacy is explained amongst pious cenobites, anchorites, and hermits, who for the most part, lead a kind of life, the conformity of which is remarkable. And thus too may be explained the severity employed at the time of the convulsions of Cevennes, and the miracles of the deacon Paris, against a woman whose efforts were specially directed to procuring for her fellow-creatures, raptures which she believed came upon her from God himself.

"Extacy usually occurs by fits its duration varies, and may be indefinitely prolonged, if the patient be not rescued from these mystical habits, and made to follow a more active and less austere kind of life. The termination of the fit is characterized by great prostration, and a decided feeling of weariness. Many of these persons have lived long; and hence it may be inferred that the extatic state does not produce an unfavourable effect on the purely physical functions, but the patients in the meantime must be fed.

"From the suspension of the voluntary movements, and of the exercise of the senses, extacy bears some resemblance to catalepsy. In the former, the sentiments and intellectual operations are exalted; in the latter, all the faculties of the soul are in the most absolute repose. By asking the patient who has just had a cataleptiform fit, to give an account of the intellectual phenomena, of which he preserves a remembrance, it is to form an opinion as to the nature of the nervous affection, whereas the external symptoms do not throw any light on the differential diagnoses between extacy, and catalepsy. Many hysterical women have visions and hallucinations much in the same way as extatics. At the end of the fit, or extacy, they sometimes complain of oppression, and shed abundant tears, as in hysteria, and hence these two affections also have several points of resemblance. Opium eaters are also in the habit of cleaving the celestial spaces, and of tasting all manner of beatitudes: but these persons betray by the petulance of their movements as well as by acts of violence, the internal transport by which they are agitated. Yet even hypnotism reproduces some of the phenomena that are more especially habitual with persons in the state of extacy. Hippocrates, however, does not appear to establish any important difference between extacy and phrenetic delirium. In the 4th century, some doubt was felt as to the soundness of mind of Simon *Stylites* whose extacies were sometimes of an alarming duration, and almost similar to catalepsy. Sennert attributes extacy to emotions of enthusiasm. To us it appears to constitute a variety of the [illegible] *delirium*. For instance, [illegible] not monomania [illegible] espe-

cially remarkable for the exaltation of certain sentiments, the concentration of the ideas and the rapidity of the hallucinations? The pious Baillet confesses, that even in the time of Saint Theresa, she was suspected of being possessed by a demon, and that it was debated whether she should not be exorcized. The extatic form of delirium is far from being rare in lunatic asylums, and indeed it is only in these establishments that one can learn to recognize all the lesions of the intelligence and of the affective passions, all the varieties of hallucinations which tend to suspend the exercise of the senses, of the voluntary movements, and to impress on all parts of the face and body, the expression that has been assigned to catalepsy. We have seen several of those patients keep their bed for months together, the head and neck stiff, the limbs inflexible and stretched, allowing themselves to be lifted up like a dead body stiffened with cold, and without obeying even when stimulated, any voluntary movement, manifesting neither hunger nor thirst, and only swallowing with extreme slowness, and at long intervals the semi-liquid food that had been introduced into their mouths. In our age, and under our climate it may be affirmed that the mystic extacy is the least common. It has, however, been observed amongst young seminarists, amongst some Irish protestants, and hysterical women. This disease may break forth amongst ourselves at any moment, under the influence of certain moral dispositions, and become diffused in the same manner as epidemic nervous affections.

"The phenomena of extacy all depending on lesions of the cerebral functions, arise, no doubt from a pathological condition of the great nervous centres. The incontestable predominance of amorous dispositions in certain extatic women, might lead us to suppose, that in some cases *a uterine* excitation had preceded the disorder of the encephalon, and had contributed to its production. But may we not also consider as a symptom belonging to extacy, that exaltation that prevails in certain affective faculties of extatic women?

"It is very difficult to obtain the guidance of pathological anatomy in extacy. When the phenomena are almost instantaneous, as for instance in the cases of St. Cyprian, Tasso, Mahomet, Cardan, &c., the cerebral lesion disappears at the same time as the fit, and the opening of the body afterwards shews no traces. In the insane, with whom the state of extacy is continuous, one is always in doubt whether the cataleptiform attitudes may not be commanded by the will; a patient hears the voice of God commanding him not to stir; another is under the influence of the idea that he will be put to death if he makes the slightest attempt to move; and thus the physician runs the risk of being mistaken as to the real nature of the malady before him, and if the patient die, he cannot decide positively, at the *post-mortem* examination, whether he has died at the time of the extacy. For this reason, therefore, we refrain from entering into any necroscopic details.

"The treatment of extacy that has become almost habitual, differs in no respect from that of other forms of monomania. Mystical extacy is dispelled by frequenting society, by a change of the habits of life, and by active labour, which prevents that fixed contemplation of a purely speculative and intellectual life. As most extatics feel a deep complacency in their extatic sensations, great perseverance and tact are sometimes required in the application of the means of treatment. Change of place, travel, exercise on foot, or an animated conversation at the time when the return of the fit is dreaded, will often prevent its invasion; the moment, especially when the senses begin to lose their excitability, is the most favourable for stimulating them, shaking the patient, forcing him to walk, and shocking him by dashing his face with cold water; when the fit has come on, the stimulation of the senses must be very moderate, indeed, it rarely produces any effect. The sounds of music, the smell of ammonia, loud shouting, or the application of sinapisms, suffice, in some cases, to put a stop to the extatic crisis. When the duration of the phenomena is prolonged, as hunger contributes to exalt the cerebral functions that remain active, it will be proper to introduce by the mouth or nostrils an œsophagus tube to convey nourishment, as also to protect the body from the effects of cold in the inclement season. Simon Stylites was almost dead from exhaustion and cold, and seemed far wasted, when he was taken down from his pillar almost a corpse. In the cases of females, particular indications are often sought to be fulfilled by the use of the hip-bath, composed of a decoction of the black mulberry, of camphorated enemas, or composed of marsh-mallow decoction and assafœtida, and by the use of cooling nitrated drinks. Bleeding is seldom proper, sanguineous plethora being but rarely coincident with extacy; very often on the contrary, we have to substitute for fasting, regular meals of nourishing food."

LESIONS OF THE INTELLECT IN THE STATE OF DEPRESSION.

These lesions comprise:—1° chronic delirium, melancholy, the lypemania of authors; 2° acute demency, acute stupor, or cerebral œdema; 3° simple demency, with or without paralysis; and 4°, imbecility.

CHRONIC DELIRIUM, MELANCHOLY, LYPEMANIA OF AUTHORS. (CHRONIC CEREBRITIS.)

When acute mania is not followed by cure, it degenerates into a chronic delirium, which is nothing more than the commencement of a demency, more or less remote. In this disease of the brain, as in those of other organs, the state of excitation is succeeded by a graduated depression which leads to a diminution of the faculties. The patient becomes silent, or at least speaks but rarely; the organic functions are performed with all the appearance of perfect health, but the intellect is profoundly altered; it has lost the energy which it can never regain. At certain times, a few exclusive ideas may still be detected as the chief feature of the delirium, and sometimes too the reason seems sound on other subjects. And this maniacal delirium often passes into the state of incurability, by assuming the appearance of a kind of chronic monomania, or by still continuing to exhibit some fragment of the intellect. This chronic state of insanity has been distinguished into two kinds, monomania with excitement, or monomania, or melancholia with depression, under the name of lypemania. In a physiological point of view, these distinctions are not entitled to the importance that symptomatologists have attributed to them; they embrace a well known period of insanity, of which the termination is but too certain. Whether this transition be long or short, whether it be marked by divagations of gaiety or of sadness, turning on a few ideas only, or on all, it always ends in demency. We here see the cerebral irritation which had been superacute in furious mania, passing into the chronic, indolent state with only some few moments of re-action, and presenting all the symptoms of chronic cerebritis, in which the brain, which at first had been only affected as an intellectual agent, becomes subsequently impaired in its functions of motility and sensibility.

It may happen before it degenerates in this manner, that the delirium may appear to remain stationary for a considerable lapse of time, or at least to offer only very slight variations in character or intensity. It is difficult in such cases to say whether they be still curable or not, and we should come to no definitive judgment on the question of incurability until two or three years have elapsed, without any amendment; beyond this period, instances of cure are very rare.

Let us now examine the prominent features of chronic delirium during this long period.

The derangement of the intellectual and affective faculties presents usually singularities, exacerbations, remissions, and sometimes lucid intervals, which might be taken for complete cure; but the improvement is of short duration, a fresh variety of the delirium soon succeeds to the old one, and these transformations may be multiplied to infinity. Some patients are sad, and apathetic for days, weeks, and months; and then all at once, they become turbulent, excessively loquacious, and their feelings of affection overflow with every variety of exaggerated protestation. The intervals of apparent reason may even admit of their resuming their usual occupations for a while; but afterwards the chronic delirium re-commences on the slightest cause.

Various influences may modify in the most singular manner, this uncertain and variable state of the cerebral faculties; great heat or intense cold alike have the effect of agitating the insane. Contrarieties, sudden emotions, and afflictions produce the same effects, and cause relapses, while, on the other hand, and by a happy contrast, the same causes have been known to produce an unexpected cure; but these are rare exceptions. In chronic delirium the catamenial period in women has much less influence than might have been supposed; they wash in cold water, run about in their naked feet, they commit, in fact, all the imprudences that their delirium suggests, without producing any influence either on the discharge, or on the state of their reason.

The influence of accidental diseases is much more marked. Esquirol has known the ablation of a cancerous breast, and the inflammation resulting from it to be followed by the cure of insanity. Georget mentions a similar case, and several others are recorded, in which chronic delirium had disappeared after a violent fall, or a commotion of the brain. This reaction is much more manifest, although much slower, through the effect of accidental maladies: thus, we see, according as a chronic inflammation of the thoracic or abdominal viscera makes progress, the agitation of an insane patient becomes calmed, his delirium disappears, and it is not uncommon to see a patient who has laboured under chronic delirium for years, at the approach of death return to the use of reason and memory.

Amongst external causes, the influence of the moon is supposed by some respectable observers to play a great part in the production of the paroxysms in chronic delirium: and hence the name of lunatics which is still in vulgar use as designating insane or eccentric persons. Daquin affirms with great *bonhommie*, that the new moon and the first-quarter, agitate the patients much more than the full moon, and the last quarter. Esquirol, during his long experience, has observed nothing of the kind. At the Bicêtre and the Salpetrière, containing together upwards of three thousand patients, daily experience has shewn that this influence is null: all that can be said on the point is, that during some nights the insane are more agitated than usual by the unusual light that enters their rooms, and the images which it seems to them to form on the walls and windows.

But whatever in other respects, the action of external influences may be in chronic delirium, it pursues its usual slow course, with the accompaniment of its own peculiar symptoms. The patient seldom loses the faculty of perceiving objects; but he mistakes their qualities—sometimes taking a stranger for a relative, a friend, or an enemy, or transforming the house in which he lives into a palace or a prison. His hallucinations are also frequent, but they give rise only to tranquil conversations; he answers in an under-tone the voices that speak to him, or he imagines that he is acted on by secret influences of chemistry, physics, or even of the police, and he protests against them with a concentrated fervour.

The affective sentiments constantly present remarkable changes; they are either perverted or null; these changes may date from the very dawn of the malady. Love, or filial affection, are supplanted by sentiments of hatred or repulsion, without motive.

Persons formerly remarkable for elegance and refined taste, no longer feel anything but a profound disgust for occupation, pleasure, walking, or society.

The change of the habits, and usual ideas, is so characteristic in chronic delirium, that, in spite of the appearances of reason, we cannot pronounce for certain the patients' cure, so long as they persist; the return to the natural tastes and feelings can alone give assurance of this happy moment.

The passions become the more imperious, the less they are controlled by ideas of propriety and natural modesty. The morbid exaltation of the propensity to a union of the sexes is betrayed by all the symptoms of erotomania and nymphomania.

In others, we observe the most singular contrasts of joy, sadness, or terror: some, always gay, sing, dance, and laugh incessantly, and nothing can disturb their happiness; others, habitually sorrowful or morose, believe themselves to be the dregs of society, or the victims of calumny and persecution. Some are timid, frightened at anything, and give themselves up to despair, or to lamentation and shedding tears.

All these symptoms but shew too plainly the general depression of the intellectual and moral faculties: and thus it is that persons in this state are incapable of comparing objects, or of forming a judgment as to their respective qualities, in the great majority of the cases. Peaceable monomaniacs may still be able to reason, or follow up a certain number of ideas on the same subject; but it is easy to see that the principle of their reasoning is erroneous, and besides the slightest contradiction frets and irritates them, and causes them to wander again.

The remembrance of circumstances anterior to the disease appears to be wholly lost on some patients; or if they retain any confused traces of them, it is only to pervert them, recurring to them incessantly as the subject of all their disordered thoughts. It is the contrary in acute mania: the patients when sincere, recollect very well all they did during the delirium, even to minute details, and the most secret motives of all they may have said or done, but these avowals are not easily obtained from women.

In chronic delirium, the consciousness of the present state disappears, and the patient gives way to the most ridiculous exaggerations. Almost all believe themselves to be in perfect health; they are astonished and indignant at the steps taken concerning themselves, more especially as regards the medical treatment they are ordered to follow: in their own opinion, they don't require a physician, as they eat and drink well and have no complaint, and that if they sleep badly it is owing to the forced situation in which they have been placed. Others, however, though few in number, acknowledge that there is something wrong in the head, that they cannot longer think, that their actions are wrong, but that they cannot help it; sometimes this feeling of impuissance and decomposition throws them into the deepest discouragement.

They have no longer any will; they act without any sustained motive; or if, influenced by their ideas, they are impelled to reprehensible acts, which are merely the offspring of false and evanescent sensations. Amongst almost all of them, we observe an apathy and an irresoluteness which prevent them from coming to any precise determination; their will and memory are alike impaired; they forget, or remember but imperfectly, the knowledge they had acquired formerly in science or art.

It has been asserted that all these intellectual disorders are derived from the lesion of a single faculty, the attention. Undoubtedly, the attention is always impuissant in delirium, because it supposes a continuity, a force of will that is no longer possible; the attention is null in the maniac, while it is but too deeply fixed in the monomaniac, and in the latter it is the effect, and not the cause of the cerebral disease. Such are in general the alterations of the intellectual faculties which constitute chronic delirium, the varieties of which are multiplied to an endless extent by their combination with each other: they form one of the most numerous classes of the insane. They may also be observed in people living in society, but under forms that are scarcely apparent, and with shades of oddity so delicate, as almost to escape detection. Thus we constantly see persons who surprise us by the strangeness of their manners; it sometimes shows itself in a levity of words and actions which has some analogy to demency, or in a dullness of spirit that borders on it still more; we meet with passions, tastes, imperious and tenacious habits that resemble monomania; sometimes it betrays itself by an impulse for speaking, obliging, throwing everything into confusion, a muscular excitement, a rapid succession of fatiguing ideas, to which we are constrained to submit and even to respect, through the fear of detecting beneath it a real insanity. How many persons in good society, but ignorant and uninformed, who take a pleasure in occupying the attention of their hearers with stories of pleasures, pains, hopes, and persecutions, that have never existed, save in their own imagination, and this too with such assurance, vividness, and sensibility, that we are deceived up to the very moment they belie themselves? What is the limit between these erroneous reasonings and the false judgment of chronic delirium? In such cases, great tact and experience are necessary to discern what is natural from what is morbid; but in the one case as in the other, we recognize, unhesitatingly, a poor and feeble intellect.

OBSERVATIONS ON VARIOUS DEBATABLE QUESTIONS ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.

By Dr. Clay, Piccadilly, Manchester.

No. I, Second Series.

(Written expressly for the "Medical Times.")

Subjects:—*Uterine Structure—Arguments in favour of its Muscularity—Supply of Nerves—Arrangement of the Uterine Textures—Different Contractions arising from the different Arrangements—Gestation—Parturition—Protracted Gestation—Natural Labour—Definition of Natural Labour generally erroneous, &c. &c.*

It appears almost incredible, and yet it is no less a fact, that so important an organ as the uterus (which even in an unimpregnated state is of considerable size) should, in reference to its anatomical structure, be so little understood. Many writers maintain its structure to be decidedly *muscular*; whilst others, as rigidly maintain that it has not the characteristics of a true muscular organ—consequently, in their opinion, it is *no muscle*. Now it is certainly true, that if the definition given to muscular bodies by many of the older, as well as more modern writers, is to be considered the *sine quâ non* of perfection, and that all structures, not falling strictly within that definition are to be considered as something else; we must search for some other explanation, as to the cause of these powerful contractions to which this important organ is subject under the various circumstances of parturition, &c. I believe if this question were to be decided by practical accoucheurs, a very large majority would be found to give their opinion in favour of its muscularity,—and of those that deny it, they do so with considerable qualification. I think few will be disposed to deny that the uterus in a gravid state is of a fibrous texture, and those who deny its muscular action, offer no satisfactory explanation as to what the action is which they wish to substitute *for* muscular; certainly, there is not anything more analogous to what is commonly termed muscular action, than that exhibited by the fibrous texture of the uterus when in a state of action, as in parturition. It requires a wide latitude of the imagination to reject the principle of muscular action, whilst endeavouring to explain how this powerful organ expels its contents—a latitude that I feel no inclination to indulge in, since I have long been of the opinion that the uterus is *a muscle*; that its action, when excited, is truly muscular; and that there exists no other known law to explain the manner by which it is enabled to expel its contents. The different layers of reticulated fibres of which the coats of the uterus are composed, will, I think, when duly considered, explain the plan of action to which these fibres are subject, and which, to my mind, satisfactorily point out its muscularity, viz.:—by the reticulated character one fibre not only acts as a fulcrum on which another's action depends, but also acts as a point of insertion to a third, and so on throughout the whole series of fibres stimulated, ensuring the contraction of the whole mass, or at least that part of it which is supplied by one class of nerves, proceeding from one particular source. Much discussion has arisen as to the source from whence the uterus is supplied with nerves; some authors considering its supply to be directly cerebral, others, chiefly spinal. I have been led, chiefly from practical observation, to believe that it can be demonstrated, that the supply is both cerebral and spinal in pretty nearly equal proportions; that the distribution of each of these nervous tissues is on different parts of the uterine organism, and different results are produced from stimulating one class of these nervous tissues to what are observed from stimulating the other. It is also probable that the lateral walls of the uterus are supplied directly from the cerebral mass, and comprise the transverse circular reticulated fibres of the uterus, which, when in action, produce those grinding pains observed in the earliest stages of parturition, familiar to nurses and midwives as belly pains, requiring, as yet, no interference on the part of the accoucheur, but which, in true natural labour, precede all other kinds of pain. It is during the action of these fibres that the process of dilatation is accomplished. Dilatation of the os uteri is the special object of these particular contractions, and any other result is not in strict accordance with the rule, which Nature, in her wise laws, has set down to be followed. On the contrary, that portion of the uterine structure supplied by the spinal class of nerves is chiefly from fundus to cervix, these longitudinal fibres are most probably arranged in another and distinct portion of the uterine coats, and when stimulated into action, produce pains of a very different character to those before spoken of, and in truly natural labour succeed the transverse, or primary dilating pains. The secondary pains I am now speaking of are marked by strong bearing-down efforts, the result of which is, the expulsion of the uterine contents. Such pains are felt in the loins and down the thighs, accompanied with spasmodic affections of the muscles of the thigh, and leg, indicating to the practical attendant a rapid progress of the case towards the completion of parturition. It will be my endeavour to prove in the following observations, the truth of these speculations by practical demonstration. In true natural labour then, the first step of nature is, to excite the transverse muscular fibres into action, which is accomplished by their having arrived at the utmost state of tensity; perhaps no strictly limited period of time is necessary to produce this excitement to action; it has been stated thirty-nine weeks, plus one day, but it is quite possible, that this matured state of tensity may be arrived at, a day or two short of, or a day or two over, the time specified and still be perfectly natural. It is extremely difficult to procure precise data of the exact period of conception, and so long as that difficulty remains, there will always be an uncertainty as to the exact period of matured utero-gestation: it is this uncertainty that has led to so many absurdities in respect to protracted gestation, very many of such cases, having no foundation in fact, but the fertile imagination of enthusiastic minds; I have taken no little trouble for many years, to ascertain what credit can reasonably be attached to such recorded cases; and, I am convinced that a majority, (and that not a small one either) will not bear minute inspection, and are entitled to but little credit. As it is, however my intention to take up this subject shortly, I shall not at this time say more about it. The period of utero-gestation, may be, as we have stated, a little more or less, than that generally admitted, and still be natural, in consequence of the precise time of conception being uncertain; much allowance must also be made for the rapidity, and extent of growth of the uterine contents during gestation, the state of plethora, or debility of the maternal system, and of the morbid action that may be present in either the maternal, or fœtal systems. When the time has arrived for the uterus to expel its contents, the transverse fibres are first put into action, the result of which is the dilatation of the os and cervix uteri. When this is in a great measure or entirely accomplished, a new action is stimulated by the second class of nerves, taking their origin from the spinal column; this second order of nerves is roused into action by the descent of the membranes, and head, into the pelvic cavity, pressing upon, and stimulating into action a series of nerves hitherto held in a state of quiescence, the moment this secondary action begins, (which is the action of the longitudinal uterine fibres which

are arranged from fundus to cervix) the result is bearing-down pains, or efforts of expulsion, and in true natural labour should continue until the whole uterine contents are expelled. Thus, I am of opinion, that the definition of true, natural labour, is not yet correctly defined; for if by natural labour, is to be understood the progressive development of certain actions, necessary to the fulfilment of the object in view, every deviation from that true line of proceeding, must be considered as unnatural, and it would be well if teachers in midwifery would particularly bear this in mind. It has been too much the fashion to consider natural labour that which has a certain mechanical presentation, and the completion of the process within a certain limit of time. Thus, though writers express their definition by variously turned sentences of our language, yet the outline is generally this: *"when the head presents, and having made its descent into the pelvis the face turns to the sacrum, when the entire expulsion of the foetus and secundines is concluded within a period of 24 hours without any artificial assistance."* Some writers have been candid enough to admit, that, to this general rule there may be some exceptions. And it is with the view of pointing out some exceptions, that I have undertaken the following observations. It is quite evident, that all that is required by the definition may be strictly accomplished, and yet after all, the labour *is anything but a natural one*, as I shall now endeavour to explain.

(To be concluded in our next.)

PROGRESS OF FRENCH SCIENCE

FROM OUR OWN CORRESPONDENT.

Paris, March 27th, 1844.

On Accidental Contraction of the Limbs; by Dr. Morel Lavallée.—(Causes continued.)—Rheumatism has been considered a cause of this affection. Delpech only looked upon it as a secondary cause, possessed however of very great power in inducing this deformity in the fibrous and muscular tissues. MM. Duval and Bonnet as well as the author, have recorded cases of contraction arising from the same cause. To its influence also must be ascribed the production of contracted joints in arthritic and scrofulous swellings of these parts, rather than to the liquid effusion within the joint. The deformities produced by a totally different disease have been by authors erroneously ascribed to the influence of rheumatism, and accordingly they have confounded both under a curious compound name, *syphilitic rheumatism*. Syphilis, it is true, affects the muscles, and manifests itself by some of the pathognomonic signs of rheumatism; a fact which almost all the authors who have written on this subject, from Petit Radel down to Dr. Ricord, have mentioned; the former expresses himself thus, (*,) "The pain which syphilitic rheumatism produces is sufficient, when it lasts some time to cause a contraction, very difficult to get rid of." Professor Chomel (†) states that "contraction of the muscles is often consecutive to rheumatism, neuralgia, convulsions, syphilis, &c." Dr. Lagneau goes still further, for not only does he mention the influence of syphilis on the muscles, but he likewise defines the species of lesion with which these organs are affected. "The venereal disease" says this author, "when it affects the muscles of the limbs produces a chronic phlegmasia, which causes permanent flexion, known under the name of syphilitic contraction, it is however an accident which has been but seldom observed."

But it is principally to Dr. Ricord that we are indebted for having again brought to notice, this neglected if not totally forgotten disease. This he accomplished, by giving a detailed description of facts which had hitherto been mentioned, but particularly, by indicating the means of curing a disease which was so rebellious to the various remedies known at the period when Petit Radel practised. All the patients that came under the observation of Dr. Ricord, presented symptoms of tertiary syphilis, with indurated chancres. The contraction appeared in one case three years and in the other ten years, after the cicatrization of the chancres. A man, ætat 30, was affected with an indurated chancre, which having been neglected, was followed in about two months after by secondary syphilis. A mercurial treatment was then prescribed and a radical cure was supposed to have been obtained; ten years after, the patient was attacked with nocturnal pains in the bones and muscular contraction of the flexors of the left fore-arm. Six months before he consulted Dr. Ricord, the fore-arm formed a right angle with the arm, preventing extension. This distinguished surgeon prescribed the iodide of potassium, and five weeks after, the cure was complete. A year has since elapsed and no relapse has taken place. * Unfortunately in other cases the interval between the date of the primary sore and that of the muscular contraction, is not so exactly noted. Syphilitic contraction exists sometimes alone or is accompanied at other times with deep seated tubercles in the throat.

Position generally acts simultaneously on the two orders of tissues, but its influence may be divided under two heads, according as it is an instrument employed by nature or the physician. But evidently in the retraction of the palmar aponeurosis, position is not near so powerful a cause as compression. In the feet, the compression produced by too small a shoe produces the disorder in a peculiar manner. Thus a dandy is often affected with contraction of the toes from wearing tight shoes; it must not however be forgotten that this infirmity may be produced or at least favoured by a hereditary disposition, (Boyer and Dupuytren.) The Chinese, it is said, squeeze into a narrow space the toes of their little girls, to prevent their infidelity when married. This deformity being rendered permanent by long continued pressure, walking is almost impossible. Among the latter causes, the simplest is that when, on account of a different limb, a healthy articulation is kept motionless for a given time. Whether the limb is bent or extended, its stiffness is always produced by contraction of the muscular or fibrous tissues. From thence arises the impossibility of bending the knee on the removal of the apparatus for a fracture of the thigh, when it has been kept extended, or of stretching it when it has remained bent during the treatment. In sprains, in addition to the immobility caused by the pain, each movement produces *engorgement* of the injured tissues: thus a sprain treated without rest is sufficient to cause contraction as will be shewn in a case of Dr. Jobert de Lamballe. Fractures, luxations, wounds, abscesses and other lesions of the limbs, produce in various ways the union of these two influences, but unreduced, accidental and symptomatic luxations, have also another and special manner of action; the extremity of the bone displaces certain muscles, shortening them by causing them to deviate from their normal direction, and at the same time their antagonists may be relaxed by the diminution in the distance between the parts to which these extremities are attached.

In order to study the mechanism of the contraction of normal tissues, taking a rapid synthetical review of what has been said, we will perceive that the shortening of the parts is sometimes *primitive*, and at others *consecutive* to a faulty position of the limb; that these two species may be by turns cause and effect. Thus, when muscular retraction has its source in a disturbance of the central nervous system, what takes place, and how is it established? The equilibrium is destroyed between certain muscles and their antagonists, and the limb yields to the action of the strongest. This predominance of power is made manifest at first by spasms, convulsions, contractions, &c., all of which, however, do not yet prevent muscular relaxation, but if these spasms of certain muscles, are frequently repeated and that for a long time, then the part becomes gradually and permanently contracted. This is the origin of most club feet. The muscles spasmodically contracted are capable of again resuming their former healthy state as soon as the exciting cause of the spasm has ceased. Should this, however, continue in force for any considerable period, organic, may take the place of what was before but functional lesion. The muscle now becomes permanently shortened and atrophied; and any attempt at extension can only succeed by a display of force sufficient to cause rupture of the contracted muscle. This assertion has been verified by the result of those cases in which M. Louvrier's apparatus for remedying muscular contraction, has been tried.

3° *Accidental fibrous tissues.*—The causes of contraction of the limbs by accidental fibrous tissues or cicatrices will be now briefly enumerated. The albuginous layers or bands under the integuments on the back of the hand, observed by Dr. Bourier and others, are not newly formed products, but merely an hypertrophy of the fascia superficialis, or as professor Gerdy expresses it, a condensation of the cellular substance, and its change into fibrous tissue. These bands, which commence in the aponeuroses, act in a similar way as those of the hand and foot, being attached to the envelope or some other portion of the tendons, without exercising in the generality of cases, any direct action on the skin. On the contrary, cicatrices are intimately united to the integuments, and it is by its medium that contraction of the limb is produced. When a wound, without loss of substance, heals by the first intention, the fresh substance interposed between its edges produces no apparent effect, and the extent of surface is not diminished; but if suppuration takes place, a cure can only be obtained by the development of an accidental tissue, which, while filling up more or less, the space left by the solution of continuity, tends to diminish its size, and to accomplish this, draws towards the wound the skin, and surrounding parts which it covers. The cicatrix may thus form a band which projects generally in proportion to the contraction it has produced. It is unnecessary to recapitulate all the lesions which may produce these results, but merely to mention the most frequent, namely, *burns*, for they are almost always followed by this accident, on account of their size, and the highly developed contractility of their cicatrices.

Prolapsus Uteri, Cured by a New Operation: by Professor Chaumet of Bordeaux.—In attempting a cure of prolapsus uteri, the principal object to be kept in view is to confine the uterus to its usual position. This, when the prolapsus is recent and not very considerable, and the patient young, a cure may be obtained by appropriate injections, or as Dr. Pontan, a distinguished practitioner of Luchon, has proved, by sea-bathing and injections with Bareges water; but when the organ has become completely prolapsed and hypertrophied, these remedies are of no utility. In these cases, Professor Chaumet recommends the following operation:—1° Remove a portion of one side of the walls of the vagina, as advised by Marshall Hall and performed by Drs. Gerardin and Laugier, Professors Velpeau and Berard; 2° Amputate the whole or part of the cervix uteri. The advantages to be derived from this modification are: (*a*) a modification in the size and weight of the uterus; (*b*) a decrease of the hypertrophy, first by the loss of blood which will necessarily follow the operation, and, next by the suppuration which inevitably takes place; (*c*) the contraction of the cicatrix of the remaining portion of the cervix and its union with that of the vagina. In a case operated on by Professor Chaumet, the result was in every respect satisfactory, and although eight months had elapsed and the woman had been occupied in the most laborious duties, she continues cured. *Case.*—Catherine R., ætat. 35, of a sanguineous temperament, and strong constitution, five years ago, after her first accouchement accomplished without difficulty, was notwithstanding affected with descent of the uterus, which gradually increased until the prolapsus became complete. On entering the hospital on the 8th May 1844, she presented the following symptoms; emaciation, extreme debility, small pulse, pale skin, inversion of the vagina, the mucous membrane of which was thicker, darker, and dryer than natural. The uterus hung between the thighs, forming a tumour of the size and shape of the fœtal head. This descended half way down the thighs when the woman stood up. The cervix uteri was considerably hyper-

* (6) *Petit Radel, Cours des maladies syphilitiques*, p. 12, 1812.

† (7) *Dictionnaire des termes de medecine*, Paris, 1828. vol. 2.

* *Gazette des Hôpitaux*, serie 2 vol. 4, p. 8. 1842.

trophied, the lips were swoln and of about twice their normal size: through the os uteri, which hardly permitted the introduction of a gum-elastic sound, a muco-purulent, ropy, and odorous liquid escaped; two ulcerations existed on the tumour, one about an inch in diameter, on the anterior, the other about nine lines in diameter on the posterior lip of the cervix: finally, above the pubis, the integuments had sunk in, and the rest of the abdomen was flattened. After removing the complications by baths, enemata, gentle purgatives, a tonic diet, rest, locally emollient poultices, and frictions with mercurial ointment, united with belladonna, the operation was performed as follows. The patient was placed as for lithotomy, a square portion of the vagina about an inch in diameter extending from the labium to the cervix uteri, was removed, two arteries that were divided were next tied, and the edges of the wound united; the cervix was then cut off with the bistoury and the uterus reduced. On the introduction of the finger, this organ was found to be about three inches from the vulva. A plug of lint covered with a bit of linen smeared with cerate was introduced into the vagina, and kept in situ by an appropriate apparatus; compresses, wetted with an emollient lotion, were constantly applied to the hypogastrium: and to obviate the inconveniences arising from the flow of urine over the wounded parts, a sound was placed in the bladder. To check the leucorrhœa, injections were thrown up into the vagina twice or thrice a day, they were at first emollient and cold, afterwards tonic and astringent; the patient was placed on an inclined plane, the inferior extremities being at the summit: she was kept in this position for six weeks. In three months and a half after the operation, she was permitted to get up. No consecutive accidents took place. The actual cautery was employed, to consolidate the cicatrix. In order to procure the return of the catamenia, the following remedies were prescribed: mustard foot-baths; dry cupping to the hypogastrium and internal portion of the thighs; ℞ extr. gentian grs. iij aloes. socotorin., hydr. chlorid. aa. gr. j. pilula mane nocteque sumenda.—(*Bull. de l'Acad. Royale de Méd.*)

On the Presence of Iodine and Bromine in Mineral Waters containing Chlorine: by Dr. Cantu, Professor of Chemistry at the University of Turin, presented by Professor Dumas. In 1823, the author announced the presence of iodine in the sulphureous mineral waters of Piedmont. Since then, by a series of experiments on this subject, he considers that it may be established as an axiom, that in all substances which contain chlorine, iodine and bromine are also contained in the state of bromide and iodide.

On the Presence of Arsenic in the Fœtus and its Dependencies: by M. Louis Audouard of Beziers. —From a series of experiments on rabbits, the author concludes: 1° That poisons, when soluble, penetrate into the fœtus, provided that the death of the mother does not take place immediately after the ingestion of the substance. 2° That whenever it may be supposed that a female with child has been poisoned, the poisonous substance must be sought for not only in the mother, but likewise in the placenta, the amniotic liquid, and the fœtus.

On the poisonous effects of the Vert de Schweinfurt, by Dr. Blandet.—This memoir is written to illustrate the poisonous agency which the above salt—a compound of acetate of copper and arsenious acid—exercises on the men who use it in stained paper manufactories. In these factories men are employed, whose business is to brush the paper after the colours have been laid down, in order to make them look the more brilliant. It is on these that the above and other poisonous pigments produce the most deleterious effects. The fine particles of colouring matter disengaged by brushing, float in the atmosphere, and are inhaled and swallowed at each act of inspiration. In a short time these poisonous particles produce their usual deleterious effects. The workmen suffer from coryza, swelling of the nostrils, lips, and eyelids, these parts frequently become the seat of a papular, or inflammatory pustular eruption, the head aches, the strength fails, cholic sets in, and in the more advanced periods of the disease, the scrotum becomes œdematous, and the seat of an eruptive disease. The antidote which the workmen themselves use to remove the injurious effects of these poisonous paints are altogether useless. The antidote on which they place chiefest reliance is milk, instead of which, Dr. B. recommends the hydrated peroxide of iron, which experience has sanctioned as an arsenical antidote.

On the dry distillation of Butyrate of Lime, by M. Chancel. The researches of this writer on butyrone and aldehyde butyrique lead him to conclude that there exists a great analogy between the compounds of butyric and acetic acids, for not only is there a striking resemblance in the re-actions to which they give rise, but likewise each product evolved in the destructive distillation in the one, has a corresponding product in the other.

On the circulation in Mollusca, by M. Souleyet.—The facts announced by Messrs. Milne Edwards, and Valenciennes at the former sitting, tend to establish that the circulatory apparatus in the mollusca is always more or less imperfect, and that the veins do not exist in certain parts, but are replaced by hiatus or the larger cavities of the system. But in reality, let the blood circulate as it may, it follows the ordinary circuit, *i.e.* after having been carried by the arteries into the different parts of the body, it is brought back to the respiratory organs and from them to the heart; in short the circulation in animals of this class is as perfect as possible. The *semi-lacunary* circulation therefore must not be confounded with its absence or its imperfection, as stated to exist in the phlebenteria, by M. de Quatrefages. M. S. concludes by stating that the intervention of the digestive organs in the function of respiration and circulation, on which phlebenterism is founded, is an opinion completely erroneous.

On Chemical Combinations, by M. Laurent.—The conclusions of the author are, 1°, that all the compounds which contain a certain number of atoms of azote are divisible by two and not by four, and contain an equal proportion of atoms of hydrogen, divisible by four. 2°, that if the number of atoms of azote are divisible by four, those of hydrogen are equally so. 3°, that if the compound contains one or more metals, the total of the atoms of hydrogen, and that of these metals must be united. 4°, that if the compound contains chlorine, brome, iodine, and hydrogen, at the same time, the total of all their atoms will be a quotient of two or four, according as the number of the atoms of azote are divisible by two or four. 5°, that the same law is applicable to compounds which contain arsenic or phosphorus, instead of azote.

On the treatment of articular swellings in Horses, by Iodine Injections, by Messrs. Thiery and Leblanc. To obviate the deformity caused by the firing iron, when applied to swellings of the joints in horses, the writers guided by the success of Professor Velpeau, performed numerous comparative experiments on the utility of injections of iodine and wine, and of the application of the actual cautery, in the presence of that distinguished surgeon and Dr. Rayer. These prove that iodine injections may be advantageously employed in affections of the *bursæ mucosæ* of horses, and that in the generality of these cases, it ought to be had recourse to, in preference to the actual cautery.

Two Lusus Naturæ. M. Joly, Professor at the Faculty of Sciences, Toulouse, has written a paper, containing an account of two species of monsters, of which he calls the first, Chelonisoma, or tortoise-bodied. In this monster, the anus is situate in the abdomen, or in the centre or sides of the thorax. The sternum is cleft throughout, and the ribs which form the thorax are shortened and some of them united by cartilage. In this cavity are contained the scapulæ, pelvis, and greater portion of the monster's tail. The urinary organs are wanting and the genital apparatus imperfect.

The second, which he named Strepsisoma, twisted-bodied, was a foal, in which the lumbar spine was twisted, so that the posterior extremities were in a direction opposite to that which they should occupy. The abdominal and thoracic organs were contained in membranous sacs which hung out of the abdomen and thorax.

Academy of Medicine, Sitting of the 25th March, M. Cavent ? in the chair. Professor Dumeril addressed a letter in the name of the section of anatomy and physiology, in which he proposes presenting a list of six candidates for the vacant seat, whose rights would be mentioned at a future sitting. Adopted.

Gluten as an Aliment. M. Chevallier read a report in reply to a letter of the Minister of Commerce, relative to the utility of vegetable gluten as an aliment. The conclusions of the report are that this substance may be advantageously employed, especially in the making of ship-biscuits.—Adopted.

On Gout. Dr. Martinenq, of Toulon, read a memoir on this disease, which he considers with Drs. Roche, Reveille-Parise, and most modern authors, to be produced by too rich a blood, and by the derangement of the digestive organs. The treatment he recommends, is that by which the blood is rendered less nutritious.

On Paracentesis Thoracis; A memoir, read by Professor Trousseau.—The writer, after detailing the successful operation given in my last, remarks that dyspnœa does not render the operation absolutely necessary—that the symptoms which indicate the danger are dilatation of the chest, change of the position of the heart, diaphragm and mediastinum. In these cases, great necessity for the operation does not exist; but the case is altered when the effusion passes the median line, or if there be with the other symptoms, considerable orthopnœa. As to the inflation of the compressed lung, which occurs after the evacuation of the fluid, Professor Trousseau attributes it to the air rushing in and filling that organ.

On the Pathology of Lymph: by Dr. Bouisson, Professor at the Faculty of Montpellier.—The researches of this writer seem to prove that when an organ becomes inflamed, the lymph contained in its capillary vessels becomes modified; from being colourless it becomes red blood, in which the fibrine is increased in quantity. In acute and chronic angioleucitis, in cachectic or syphilitic diseases, &c., the alteration of the lymph is manifested either by a modification in its physical properties, or by a peculiar influence on the system. Several deductions are established, in which lymph is shown to contain blood, bile, urine, milk, &c., and that, in cancer, melanosis, &c., it is evidently more or less modified. The conclusions of the author are: 1° That the lymph evidently participates in the various pathological changes which the different organs assume. 2° That it is sometimes the cause, and sometimes the effect of the morbid symptoms observed. 3° That the part performed by lymph in the economy and its mode of formation place it within the reach of our therapeutical agents. 4° That venesection, regimen, purgatives, &c. in modifying absorption, likewise modify the production of plastic lymph.

Professor Gerdy gave the details of a case of a hydatid tumour removed from the thorax of a child three years old, which also contained a substance of a doubtful nature.

GARLAND DE BEAUMONT, D.M.P.L., & S., &c
Honorary Physician to the Spanish Embassy.

EXTRAORDINARY MEETING OF THE PARISIAN MEDICAL SOCIETY.

A numerous meeting of this body was held on Tuesday evening, the 1st instant, pursuant to a requisition inserted in *Galignani's Messenger*, to take into consideration the mode in which diplomas are obtained by unqualified individuals in certain German Universities, and to adopt such resolutions as may tend to afford security to the public, and at the same time to uphold the dignity and interests of the medical profession.

Amongst those present, were Baron Dubois, Clinical professor of midwifery to the University of Paris, Drs. Ricord, Lonnellan, Garland de Beaumont, Brierre de Boismont, Olliffe, McCarthy, Davison, Clancy, Taylor, &c.

The chair was taken at 7 o'clock, by the President Dr. M'Carthy, who having stated the object of the meeting, vacated it, and was replaced by the Vice President, Dr. Clancy.

The following resolutions were then unanimously adopted.

1. Proposed by Dr. M'Carthy, seconded by Dr. Olliffe:—That this Society feels itself called upon to notice two articles which appeared in the London *Medical Times* of the 8th, and 22nd March, 1845, headed "Value of a Giessen Diploma," and to denounce the traffic carried on by the University of Giessen.

2. Proposed by Dr. M'Carthy, seconded by Baron Dubois,—That a committee of three be appointed to communicate with the University of Giessen, to protest against the late disgraceful transactions.

3. Proposed by Dr. Kneeland, seconded by Dr. Ricord:—That it is the opinion of this Society, that no regularly educated medical man should meet in consultation, or recognize in any way, as qualified practitioners, individuals who have no other title than the Giessen diploma.

4. Proposed by Dr. Olliffe, seconded by Dr. Taylor:—That M. Orfila, Dean of the Faculty of Medicine of Paris, (whose efforts to protect the public from charlatanism and imposture, and to uphold the dignity and interests of the Medical Body at large, have at all times been so prominent,) be requested to extend his protection to the regularly qualified practitioners resident in Paris.

5. Proposed by Dr. Redfern, seconded by Mr. Webb:—That this Society denounces entirely the practice of granting diplomas by any University, without being perfectly satisfied, by a personal examination, of the fitness of any candidate for their degree.

PROGRESS OF GERMAN SCIENCE.

By Sigismund Sutro, M.M.

Fallacy of M. Weber's Test to Distinguish between Bitter Almond and Laurel Water.—This test, which is nothing more than the effect of aqua ammoniæ upon the above distilled waters, has been pronounced erroneous by Professors Martius and Osswald. Weber asserts, "that liquid ammonia produces no change when added to bitter almond-water, but that it changes laurel-water from a transparent to a cloudy milky liquid." Osswald not only denies this, but asserts the contrary. He says, that bitter almond-water becomes milky on the addition of caustic ammonia, while liquid volatile alkali produces, at first, no change in laurel-water, but renders it, after some time, slightly clouded. In experiments, which he had performed to investigate this subject, after the lapse of a fortnight, since the addition of the ammonia to the bitter almond-water, he found the test-tube, containing the mixed liquids, covered at bottom with a dirty-yellow, sandy precipitate; while that containing the laurel-water, which had been exposed to the ammoniacal re-agent, was but slightly coated at its sides with a dirty-white deposit. The smell of the bitter almond-water continued unchanged, while the laurel-water had completely lost its characteristic odour. May not this latter difference between both waters be ascribed to the fact, that bitter almond-water contains more ætherial oil than its analogue, laurel-water?—*Buchner's Repertorium.*

*Poisonous Effects of the Expressed Juice of Fresh Elder-Bark.**—A strange opinion prevails among the lower order with regard to the properties of elder-bark. They imagine, that this substance, if scraped from above downwards, possesses a purgative power, and that if, on the contrary, scraped from below upwards, it produces emetic effects. Having premised this statement, the writer of the present paper states, that Dr. —— was called to visit a married woman, 54 years old, of a bilious temperament. When he first saw her, she was constantly vomiting coagulated greenish matter, which she supposed was bile, and complained of violent cholic. On enquiry, Dr. —— found that she had been ill ten days before he was sent for, and that her husband had administered to her, as a purgative, about two tablespoonfuls of the expressed juice of elder bark, scraped from above downwards. To relieve the cholic Dr. —— ordered some compound infusion of senna, which was not taken, as the patient had several stools after his departure. Next day enteritis set in, and was followed by paralysis, under both of which the patient soon sunk.—*Medic. Zeitung. Russlands.*

* The bark of the dwarf-elder, Sambucus Ebulus, not that of the S. Nigra, must be that referred to in the present article.—Ed. *Medical Times.*

On the Astringent Properties of the Sporules of Fern.—In tropical countries, the sporules which cover the young fronds of the larger ferns, have been long prized as styptics. Some of these sporules, imported to England from the West Indies, have been used by English practitioners, and found to possess highly styptic properties. Hasskarl has lately brought to Holland a specimen of the sporules of the Javanese *Alsophila lurida* called by the natives *Bulu-kitang*, which have been very advantageously employed by Dr. Molkenboer, of Leyden, in the treatment of internal and external hæmorrhages.—*Dr. Seubert, in Buchner's Repertorium.*

Wöhler's New Mode of Preparing Benzoic Acid.—Benzoin is dissolved by heat, in an equal volume of alcohol, and to the hot solution muriatic acid is added, in proper proportion to form æther with the alcohol. On the addition of greater heat, benzoic æther passes over dissolved in alcohol, upon which some drops of undissolved æther may be perceived floating. The distillation is continued to dryness, when boiling water is added to the residuum in the retort, the process is begun anew, and continued as long as æther passes over. The hot water is next poured off, and deposits on cooling, some chrystals of benzoic acid. The distilled liquids are next mixed, treated with caustic potash, exposed to a heat sufficient to volatilize the æther, and finally saturated with muriatic acid. On cooling, benzoic acid is deposited in its usual chrystalline form. This operose mode of preparing benzoic acid, possesses no advantage over those in ordinary use, save the nominal one mentioned by Wöhler, namely, that by this process, benzoine is completely deprived of every trace of acid; nor does it divest the chrystals of their odorous principle, the oil, which is found equally in this as in the commonly prepared acid of benzoin.—*Annalen der Chemie und Pharmacie.*

On the Agency of Galvanism in introducing Remedies into the System.—The writer of this paper, reflecting on Davy's discovery, "that volatile substances, when connected with a galvanic battery, are invariably carried in the course of the electric current," resolved to try whether this principle might not be rendered subservient to the cure of disease. Iodine was the first remedy he determined to make trial with. After various experiments, he at length completely succeeded in introducing this substance into the system by the agency of galvanism, and effected cures in five instances in which he employed this compound therapeutic agent. As the result of his experiments, he concludes by stating, that this novel mode of employing medicines possesses advantages over the ordinary method which ought to entitle it to a trial. As not the least of these advantages, he mentions, 1°, that the topical effects of iodine or any other drug can be most readily perceived when used in this way. 2° That any injurious overcharge of the remedy used, will pass off by the negative pole; and 3°, That the constitution suffers less from remedies administered in this than in the ordinary manner.—*Dr. Klenck of Braunschweig, in Werner's Zeitschr.*

On the Importance of placing Nervous Patients in the Magnetic Meridian.—Dr. Von Eisenstein states that the earth is a large magnet, a reservoir of magnetism, which, like electricity, is both positive and negative. The human body from being subject to its influences, becomes highly magnetic, and as a consequence, electro-magnetic processes are constantly in action within it. If in the human body the different varieties of electro-magnetism preponderate not one over another, health is the result; whereas disease, developed through the nervous system, must ensue if this equipoise is not preserved. Dr. Von E. has witnessed the most beneficial effects in the treatment of nervous diseases, by directing his patients to be placed in the course of the magnetic current, with their heads towards the north.—*Opere Citato.*

THE MEDICAL TIMES.

Saturday, April 12th, 1845.

"This is neither begging, borrowing, nor robbing,
Yet it hath a twang of all of them."
Massinger's Guardian.

That infatuated, doom-smitten cabinet of incapables—the Council of the College of Surgeons—give us this week, as a further earnest of their ruin, another of their laboured essays at self-justification. We have read it with the bitter melancholy with which a Jacques may be supposed to have heard his motley fool in the forest. Alas, poor humanity! Angels might indeed weep to see the fantastic tricks of these men, pranked out in a little brief authority. We must not only, as of yore, have our imbeciles above us, but be everlastingly convicted of the fact, on their own spontaneous confession. Every fool in luck, in those days of literature, must perk his ineptitude in our faces—and rulers can't be easy in their places till they have proved satisfactorily, in black and white, "with how little wisdom the world is governed!" The arrogance of mental insignificance never, surely, reached its climax, till this manifesto saw day. Forced, like others, to witness the multiform vanities of imbecility—we are yet literally astounded at the phase before us. The mindless Councillors of the College deliver their presumptuous follies with the grave consequence with which Roman senators gave forth the edicts that conquered nations. Nonsense in extremes never assumed a more solemn or insolent aspect.

But, amid all the gravities of official self-importance, how curiously do the lighter hues of childish ineptitude interweave themselves! What, psychologically, can be more interesting than to see these imagined statesmen condescending, ever and anon, in their grand diplomatic ultimatum, to teach the general practitioners—one of the great contracting parties—how to write English, magisterially putting right, collocations of words which were never wrong! Setting out with a majestic sneer at "the *Gentlemen* STYLING THEMSELVES the National Association," (those gentlemen whom they elsewhere "individually esteem," and "refer to as highly respectable!") they talk of a solution "requiring *nicer* distinction than the Association seems to have anticipated"—suggest complacently to that body "second thoughts" upon another of their views—waggishly declare that a question by the Association was "probably intended" to stand, not as worded by the Association, but as the Council condescendingly put it—and obligingly suggest what *might* BE "the *aim*" of the Committee "*when explicitly worded!*" Poor demented children! At this very moment, one of the noblest institutions of the Empire has been thrown, by their stupid mis-government, into the most imminent danger—and they occupy themselves in giving lessons in philology, after an impertinent fashion, to the very men who hold their fate in their hands! In great matters, as in small, it is always the same when government is lodged in the hands of presumptuous incapacity. While ruin, in the shape of insurrection or revolution, has been brought, by their puerilities, into fearful proximity, one brainless ruler embroiders petticoats, another plays the carpenter, this one fiddles, and a fourth gives lessons!

In this impolitic vindication of ruinous impolities, we are first told that the "alleged injustices" caused by the Council's *administration* of the New Charter were forced upon them by Government. This is a shabby excuse, and may be branded

without ceremony as a mis-statement. The Council themselves declare that the *Government's* aim was merely the provision of an electoral body. If an electoral body were all that was required, a certain number of senior members would have done as well as a certain number of any other members. The elective privilege so bestowed, while giving all the Government is said to have asked, would have required no new grade, no new title, no invidious promotion, no outrageous displacement, and if blamed for not proceeding far enough, would have caused no protest on the ground that personal injustice had been done to any man. It would certainly have been recognised as an improvement. But such a constituency, though it would have introduced into the College that responsibility in its new government her Majesty's ministers sought, would not have given electors necessarily under the thumb of the Council—would not have given the Council the patronage of their appointment—nor would it have enabled them, by elevating "the pures" singly, to make a stab at the public's increasing confidence in general practitioners. The *Government* wanted responsibility: the *Council* wanted patronage—and Sir James Graham has been so unfaithfully dealt with by those he has confided in, that they have got their aim, and he has lost his. He has not given us responsibility, but they have got patronage. This fact, proved by the universal discontent of the members, and lasting "*obloquy*" of the rulers—circumstances admitted in the manifesto—should set Sir James Graham a thinking. We have been cruelly injured—has he not been cruelly betrayed?

But they tell us that their selections were honest. We tell them, with unpolite brevity, they say false. Honest men *would* never, *could* never have accepted such a power of selection. It was a selection that COULD NOT be just—for no twenty surgeons of the metropolis, however extensive their acquaintance, or however little affected by it in their choice, could say who were the best five hundred surgeons of the empire. They could not do right to the worthy men that owned them as brethren—and as honest members, they should have resolutely refused to do wrong; and therefore we say, that the man who gave himself, by the abuse of royal prerogative, such a disgraceful piece of patronage, must have been very nearly a scoundrel, and that those acting with him in its exercise must be conscious of a transaction which, if a virtuous brother's peace and social dignity be anything to them, should leave them many a sleepless night. How DARED Sir Benjamin Brodie—how dared any men presume to set themselves as public arbitrators who were, and who were not, the good surgeons of the realm? What justified their robbing, pillaging, and plundering their fellow members of their right, and then saying to the people of England:—"Of all the men practising surgery among you, only we—the five hundred pillagers—are worthy of your confidence?" How dared they libellously and lyingly proclaim, in May last, that they would omit no one in the list of Fellows "held in esteem by the other members of the College for his surgical experience and scientific attainments," and then omit ten thousand gentlemen whose surgical skill they had themselves proclaimed? How presumed they thus to badge, as *un*scientific and *in*experienced, the surgeons of England—their own brethren—who had undergone as good an examination as themselves? Thus, then, stands the matter. The patronage was unnecessary—for seniority would have given an unobjectionable elective body. It was most suspicious patronage, for the power of distribution was used in secret, and was unchecked and irresponsible. It was a patronage that could not be justly exercised—for no power of man could discriminate the merits that called for preference. What, then, must we say of the *honesty* of those that sought the privilege—mendaciously praying for it in the name of those members of the College that detested it? Is it wonderful that patronage petititioned for with so much probity has been distributed with so much fairness and justice?—and what can Sir James Graham mean in handing over the profession to be devoured by incapable parasites, after so scandalous a fashion?

But, then, we are told, for our comfort, that the enormous wrong done to our surgeons will vastly serve surgery! Surgery is to be advanced by the injury of its cultivators! The less the Practitioners of this country are connected with a College of Surgeons, and the more they are forced by governmental interference to confine themselves to pharmacy, the more these select Solons think will be accomplished for surgery. The truth is, these small-minded gentry give opinions on matters to them far beyond the range of a clear conception. They neither know the nature of the surgery they talk about, nor the means that will best increase it. There is no such thing as "pure surgery" in an enlightened country, as there is no such thing as a surgery which excludes midwifery. *Pure* surgery is *pure* barbarism. Your butcher is your only *pure* surgeon. Why, Brodie, who talks in silly accents of medicine, and midwifery, and pharmacy as sciences NOT COLLATERAL TO SURGERY, has made one-half his fortune by medicine; and the idea of improving surgery by limiting its high posts to an extremely small body of candidates, is one of the wildest that could enter the brain of a bedlamite. Surgery as a science will never have its true development in this country, either in height or expanse, until every medical man in the empire feels that whatever the nature of his avocations, his surgical skill, if superior, shall be certain of carrying the bell. Believe those men, carry out their reasonings to their true extent, and surgery is nothing but a system of operations. Dismemberment not cure, would seem the object of their science: a patient to them would appear not a man asking health, but a carcase inviting carving practice; and the council would never be properly constituted unless monopolised by such men as Liston. Such medicine-mongers as Brodie, and Guthrie, and Cooper, follow far too *general* a practice to suppose of their being up to the mark! in pure surgery.

In another part of this verbose piece of audacity, we are told that our principal inducement to take their diplomas, was to have a certificate with their *names* attached! How comfortable a doctrine for *their vanity*? "What a dust we flies create!" And it is added, still further to reconcile us to the fellowship and to soothe "disappointment," that there is a bye-law excluding general practitioners from the council which we swore to observe. What can this mean? *We swear to observe* a bye-law which we can neither observe nor infringe? The thing is absurd, but we suppose this judicious council, would run into an absurdity rather than omit so good an opportunity of good-naturedly suggesting that in trying to get a bye-law altered, we are perjuring ourselves? If so, what did the council when they changed the old charter and bye-laws *they* had sworn to maintain? And will they permit us to ask, was there not *another* oath—that of defending their members intact in all their "*rights?*" Was the equality guaranteed us by printed circulars, no *right?* Was our "*displacement*" from our old position no infringement of a "right?" But they deny the "displacement." What says their own manifesto of May? "The question was not whether they" (certain surgeons) "should be *elevated* to a new position, but whether they should be *displaced* from one which they previously held!" By their own statement, then, omission from Fellowship and displacement from "*previous position*" are synonymous terms! Have they then—let us ask them—protected the "*omitted*"—secured the "*displaced*" in their full rights? If not, who justly can bandy about charges of perjury? The tyrant who has infringed the constitution he swore to observe, is always prompt to talk of broken oaths of *allegiance*—oaths which he himself has annulled.

The Council, in their very full wisdom, claim immense credit to themselves as having had the opportunities and occasions required for the special cultivation of surgery, "and as possessing consequently, the qualifications for regulating the education of surgeons, and for promoting the great public objects for which the College was founded," and to shew how they have regulated the education of their members, and promoted the great public object for which the College was founded, give us this delightful view of the gentlemen they have ushered in with us to the honour of confraternity. In a very *triumphant* tone, they ask, "Would they," the Association, "include "in the list of Fellows those" members "who "have *violated the laws of their country?* "*Would they include professional paupers, and* "*persons of notoriously bad character? Would* "*they include the puffers and vendors of nostrums* "*and secret remedies, and the writers of indecent advertisements? Would they include surgeon's assistants, or those who have connected themselves in* "*business with druggists and chemists?* Would they "*include the retail shopkeepers*, who expose for sale "*cattle drugs and perfumery?* Would they, finally, "include or exclude all those who keep open shops, "and who, though ill sustaining a professional "character, are yet not chargeable with any "moral disqualification?" It is difficult to fancy anything more coolly insolent! They made as much money as they could by letting in as Members, Felons,—indecent advertisers, *et hoc genus omne*; they then purify their own clique by adroitly erecting a higher grade, which absorbed themselves and friends, and when we claim admission in the same order, they assure us, that they really must decline—the difficulty is so great of discriminating us from the disreputable brethren they gave us! If a felon be good enough for a Member, *a fortiori* is he good enough for a Fellow. He is, of all men, the one calculated to administer in a proper spirit the most *felonious* document that the sign manual, perhaps, ever touched!

In closing our remarks on this most discreditable and impolitic manifesto, we feel bound to present it to our readers as the Council's final declaration of war against its Members. There can be no longer a minute's mistake. No further treating—no further negotiation. Let them have in plenitude the whole of that hostility they have so recklessly courted. *Delenda est Carthago.* Let no communion professionally be held with the Council.

Some of these gentlemen are said to be not ill disposed to us. We will believe it when we see them abandoning a post they can no longer occupy

with honour. The National Association must form the general rallying point. IT MAY BE A COLLEGE OF SURGEONS, AND MORE, if the profession will do its duty. All minor Associations should at once join it. The Provincial Association will not be true to its own principles if it shrink from an immediate coalition; and we would respectfully urge on the Defensive Association of Surgeons at once to join with the only combination which, in numbers, in respectability, and in energetic management, *has* existed, or *does* exist, with power to achieve every long desired improvement in the profession. We have heard with pleasure of the beginning of a movement by the extra Licentiates of the College of Physicians. Might it not answer their aims to swell the force of a body which should include in its pale the whole profession, and give it a consolidation, and aggregate power potent for every good? The curricula and examination of the physicians and the general practitioners have, for years back, been pretty identical. A thousand arguments show that it would be a great march in professional improvement, by which every medical man would be physician, or surgeon, or both. "Licentiates" and "Apothecaries" should be left to the back ages they belong to. Is it impossible, then, that—including all orders of the profession in one common University—the National Association may become a great National College of Physicians and Surgeons, and hold their sittings, so useful to the profession and society, in the very halls whence now proceed the act of atrocious injustice, and the document of imbecile insolence. We will not despair of even so vast a result; but whatever happens, it is clear that the Association is the great defensive power of the Profession, and that it will do good for us in the precise proportion in which its unanimity is maintained, its force is strengthened, and its mutually cordial good feelings maintained.

The wise fellow who first termed the practice of medicine a mystery, deserves credit for seeing further than others into a mill stone. No day passes, which does not bring us proof of the correctness of the apothegm with which he has graced our profession. Some two or three weeks since, we had the highest surgical authorities in the land, at fistycuffs in open court, about the propriety of a specific plan of treatment, in a very specific surgical disease. The example set by men of such professional *ton*, could not fail to be imitated by their humbler brethren. Accordingly we have had at Norwich, on the 5th inst., another Lawrence and Liston case.

An action was brought by a young lad named Gibbs, against a surgeon, Mr. Tunaley, to recover damages in lieu of a leg, which he stated to have improperly disappeared, during the defendant's treatment. The plaintiff's cart-wheel went over his foot, below the ancle joint, lacerating the posterior tibial artery, or some one of its branches. He was brought to the doctor's house, who dressed the wound with adhesive plaster, and directed the lad's friends to send for a Mr. Skolding, a chymist, if the bleeding returned. Mr. Skolding *was* called in, and bandaged the wound, in doing which he placed a knot over the anterior tibial, which, allowed to press upon the artery for a few days, caused mortification of the foot and leg, and amputation of the limb below the knee of necessity followed.

In support of the allegation of unskilful treatment, Messrs. Lewis and Colman, surgeons, of Wymondham, appeared, and gave it as their opinion that the lad was neglected, inasmuch as the gangrenous process should have attracted the attention of the person in care of the patient, fully six days before he ever seemed to have noticed it. Messrs. Mills and Nicholls, of Norwich, gave corroborative testimony; alledging that in such a case as that before them, the temporary application of a bandage might be resorted to, to check hæmorrhage, but that its continued application for seven or eight days, was indefensible, and highly injurious. They had examined the amputated limb and found the bones composing the ankle joint uninjured, though their cartilages were completely absorbed by the destructive inflammation excited by the treatment adopted.

The defendant, in justification, alleged that he had at first informed the plaintiff of the very dangerous nature of the accident which he had met with, and that his directions *not* had been attended to; that the bandage had not been allowed to remain on for a week, the plaintiff having removed it the Wednesday after the accident, when the wound was dressed, an operation which was repeated by the patient twice or three times. Messrs. Crosse, Norgate, Johnson, and Dr. Evans, all of Norwich, gave it as their opinion that the case originally was one of injury to the ankle joint, which, though not fracturing the bones, had detached their cartilages, which were consequently absorbed. They stated, in addition, that the mortification was the result of the original injury, not of the treatment adopted.

The jury after a lengthened consultation, gave a verdict for the Plaintiff, damages ¼d.

This trial affords matter of comment on more grounds than one. Without doubting for a moment the surgical knowledge of such a man as Crosse of Norwich, we beg to offer our humble opinion, as to the impropriety of receiving his evidence under the circumstances in which it was given. Nothing appears in the report of the trial which could lead us to think that he ever saw the lad Gibbs, while labouring under the effect of the accident. Had he been called in to see him, no doubt we should have had Mr. Tunaley referring to his opinion. But no such thing occurred. We find him and some four other medical practitioners coming forward to do what? To give their opinions upon the propriety or impropriety of Mr. Tunaley's deputy's treatment on the strength of the representations of both or either of these gentlemen. But suppose that neither Skolding nor Tunaley ever spoke to them on the matter—and that Mr. Crosse and his friends gave their opinions according to the evidence they had heard during the progress of the trial, we say again, *that not having seen the injury either from the date of its receipt, nor later still, when the limb was obliged to be amputated, they had not a shadow of right to give any opinion, nor should such an opinion as they gave be allowed to go in evidence before a jury.*

Here, as in Lowe's case the matter did not resolve itself into the discussion of a dogmatic point. The case stood simply thus: was gross neglect exhibited or, not, in the treatment of the lacerated wound of Gibbs' ankle? Now Mr. Crosse not having had the personal experience which would have enabled him to solve this query, could scarcely be correct in his opinion, on the ground that the intensity of the inflammation as exemplified in similar accidents might produce all the unfavourable results of the case before us.

A patient is brought to Tunaley, whose anterior tibial artery has been laid bare, and lacerated. Mr. T.'s treatment consists in covering the wound with sticking plaster, and sending the lad about his business, telling him, however, if anything untoward occurred, to call on a chemist, who in all probability knew as much about the matter as the lad himself. The chemist is called in, bandages the wound, we will suppose on the second day after the receipt of an injury which according to Mr. Crosse separated the cartilages of the ankle joint, from their attachments, and bandages too, at a period when inflammation is most naturally looked for in such injuries. Would Mr. Crosse adopt such practice in the Norwich Hospital? We are certain he would not. Would he, if his own ankle joint were denuded and his *anterior tibial* torn through remain quiet under the application of a strap of sticking plaster to the wound? We can almost fancy him, after the primary shock of the accident had subsided, with the heel of the wounded foot slightly raised, uneasily lying on his *Arnott's bed*, and watching, with the impatient and fitful eye of suffering, the evaporation of the *lotio lythargyri*, tepid or cold, from the wound, while all the appliances of surgery to keep down inflammation are ready at hand. Did Mr. Tunaley direct any thing of this sort for Gibbs? Rumour sayeth not. Did Skolding, the chemist, during his week's attendance, prescribe or direct the applications of any one of the routine remedies used on such occasions? His master's silence would lead us to infer a negative to this query. For this sin of omission he is not to be blamed—the defendant directed him to be called in—thrust honour upon him which it is no no man's nature to refuse; and, in our opinion, the defendant should not be allowed to pass scatheless for the effects of his deputy's ignorance. A farthing is rather a low estimate of the value of a labourer's leg, supposing even that he had a horse and cart; and we would humbly suggest that our Courts of Justice should prepare a tariff of prices for human members—a graduated list of the value of each extremity—a very fitting substitute, we should think, for the old "lex talionis."

As a heading of the list, we would give—

A LABOURER'S LEG (*vide* GIBBS *v.* TUNALEY). VALUE—ONE FARTHING.

THE CONSPIRACY AGAINST THE NATIONAL ASSOCIATION.

A correspondent, on whose sources of information we have much reliance, gives us, as his settled conviction, that an eccentric Member of Parliament, whose ineffectual apostacy from the imperilled cause of the Profession is now matter of common derision, is under terms to get the Government Bill passed this Session. The policy of creating an apparent division in the National Association, as a diversion that the minister can take advantage of to press forward his measure, and the insidious, side-winded eulogiums of the Bill, and crafty suggestions of good points that do not exist;—this species of policy is assumed, our correspondent alleges, as the least dangerous and indeed most feasible mode of disarming and making ineffectual the Profession's opposition. It is but reasonable to suppose, that Sir James Graham, who feels his position as a statesman much compromised by the attitude of the Profession, will, if ultimately successful, testify his gratitude in a form still more substantial than that which testified to the service of this M.P.'s silence on the concession of the Charter. About the time of that useful silence, h's brother—a tradesman—got a government birth, Assignee of Bankruptcy. But *that* appointment was only worth from one to two thousand a-year.

No. 291 **SUMMARY.** April 19.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES—MORBID AND HEALTHY,

By Dr. Knox, F.R.S.E., F.R.C.S.E.,

Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

LECTURE III.

In a subsequent lecture, I shall examine the physiology of the human cranium and face, the skeleton of the head, in fact, as a whole: that lecture I shall base on the measurements and careful examination of about 260 crania of different races and nations. But as each individual part or bone of the human body has its special physiology, its own anatomical and physiological consideration, altogether independent of, and indeed, scarcely related to, those abstract and metaphysical speculations which have hitherto passed current for physiology, bringing it into total disrepute as a useful science, I shall proceed first with the examination of each bone of cranium and face, leaving out of view for a time those beautiful and probably correctly philosophical speculations which Goethe founded on the principles of analogy; principles known to Aristotle and Newton, but most clearly expressed by Newton as principles, and rendered intelligible to all by Goethe, who applied those principles to the details of animal and human structure.*

When the student has surmounted the difficulty of naming the various processes, foramina, plates, fissures, and cavities, seen in and about the frontal bone (a school-boy's task), with which, however, the student, it is to be feared, generally completes his view, mistaking the means for the end; learning anatomy as if it were a science in itself, and not a mere art leading to the acquisition of science; the student should now examine this bone and all others, with a reference to their physiological and practical history. It matters not how he proceed with it, provided he but keep the bone before him, and in his hand. By one surface it assists in enclosing the brain; by another, it forms a part of the orbits; and by a third, that of the nostrils. The superciliary arches (arcus superciliares) are two, somewhat rough, arched prominences found a little above the orbitar margins, proceeding from below upwards, and receding a little as they advance from these margins. They are not generally very distinct in the female cranium, nor in all males; nor are they peculiarly strong in any race of men I have examined. Certainly not in the negro race: their strength, or enlarged development, would seem then to be an individual variety merely, not confined to any race or nation, but occasionally seen in all. It is in the adult oran, however, and in the male baboon where I have fancied their development to be strongest, and conjectured this development to be somehow or other connected with strong sexual desires. It may, or it may not, always coincide, but this is my general belief. The texture of the bone in these superciliary arches differs from the adjoining structure; it is open, loose, and vascular, or at least full of foramina. It merits a more minute enquiry than what has been as yet bestowed on it; the elevation of these arches, I may further remark, is not necessarily dependant on, or coincident with, any increase in the size of the frontal sinuses.

The frontal protuberances are always pointed out to the student whether they be present or not; but in fact they are only occasionally of any magnitude. In the early years of those persons who show them large when grown up, rickets may be suspected to have prevailed: or if they have not positively prevailed, at least there has been that peculiar constitution disposing to them. Every anatomist knows that the earliest ossific points in the frontal bone appear in or near these protuberances, and that the osseous fibres, so to speak, shoot from these points like the radii from a circle's centre. On each side the smooth surface surmounting the nasal spine, an elevation appears, increasing and extended outwards under the superciliary ridges as age advances; these elevations mark the situation and growth or development of the celebrated frontal sinuses; cavities which have given rise to much discussion as interfering with the general parallelism of the tables of the skull at this particular part. The facts accumulated by many observers, both anatomists and amateurs, have not as yet led to any clear notions of the signification, value, or uses of these sinuses. To say that they are placed there to lighten the bones of the cranium, might satisfy the readers of the "Bridgewater Treatises," but not any sound anatomist. They form a part of a system of cavities which will require to be considered in a lecture apart; the sphenoidal, the ethmoidal, the maxillary, and the mastoid cannot be viewed separately from the frontal. This much may be said here; they are not peculiar to any race of men, nor is their development more marked in one race than in another. So far, then, their enlargement beyond the ordinary size seems to be "individual." Small generally in women, and scarcely existing before fifteen in either sex, hence the beauty of the youthful brow: such bony projections disfigure the brow when very prominent, and hence the loss of beauty in this part as age advances; age, marked by wrinkles and by an undue prominence of the skeleton, driving from the mind of the observer all ideas of beauty. To disfigure an otherwise beautiful countenance, we have only to let the outline of the skeleton become visible; high cheek bones; sharp angles of the jaws and chin; angular processes of the frontal prominent; how carefully are these concealed in the antique whether male or female! Ever so slightly observed, they destroy all form and beauty; the mind of the observer instinctively discovers the invisible, or that which nature intended should not be visible, and reverting probably to an inherent dread of dissolution, admits, though with pain, that beauty has fled from some beloved object—consoling itself however with the expression which may still remain, and with intellectual and other associations.*

On various sections of different bones which ought, if possible, to be placed before the student he will observe that those sinuses are not unfrequently very large; no external appearances would have led him to suspect this; and they are occasionally small, when from outward form he would have guessed the contrary. Their extent then varies exceedingly, nor is it possible as yet to reduce this to any physiological principle. One is occasionally much larger than the other, and occasionally one is absent. Their uses and their signification then are entirely unknown; the mucous membrane of the nose, or its epithelium, at least, passes into them, and air penetrates into these cavities no doubt. Berter seemed to think that these sinuses are really not formed between the tables of the skull, and I have myself seen appearances as if the diploe and a portion or layer of the inner table might be seen on the exterior wall of the sinus. But such appearances may, after all, be deceptive.

I come next to speak of the *planum semi-circulare* of anatomists, and of the frontal crest, crista frontalis, surmounting and circumscribing it superiorly and anteriorly.

The *planum semi-circulare* of the os frontis, is that portion of the bone assisting in the formation of an extensive and somewhat rough surface, to which the temporal muscle is attached. The parietal, temporal, and sphenoid bones, assist in forming it. As regards the frontal bone, it does not generally present any remarkable feature, excepting by the presence of that elevation or crest, extending from the outer angular process until it meets a similar one on the parietal bone, with which it is obviously continuous. This ridge or crest is generally but little marked in man, but in some quadrupeds, and occasionally, in man himself it forms a distinct crest; that is a fronto-parietal crest, having no reference whatever to the temporal muscle, but forming a remarkable feature of an unknown signification in those crania wherever it is found. I have called it the external frontal crest to distinguish it from one or rather two, which seem disposed occasionally to form *mesially*, that is running up the centre of the bone in the line of the proper frontal suture, with which suture, however, they have not necessarily any necessary connexion. These crests are not peculiarly strong in any race; remarkable in individuals merely of all the races. I think I have seen them strongest in the Hindoo skull, but this was merely on one or two crania, and not at all common to the race. The negro does not show them more strongly than others; nor the Australian. As they pass uninterruptedly from the frontal to the parietal, and from that to the temporal, they evidently in all, belong to one formation. They naturally induce us to attach less importance to the system of the sutures which also disappear with age, thus, shewing their temporary character; and they unfold higher analogical principles in the formation of the cranium than

* Dr. Thomas Traill, Professor of Medical Jurisprudence in the University of Edinburgh lecturer on a great variety of subjects, has denounced the whole of Goethe's doctrines to be "absolute nonsense; absurd." The joining an establishment seems to have affected the doctor's intellects.

* See the Theory of Beauty in a former No. of the *Medical Times*

the mere anatomist might be disposed to allow. But however, this may be, we shall find I think when we come to consider (as I shall do, when considering the ossa parietalia,) the whole system, of which these frontal crests form but a part, that their nature has not been carefully considered by the human anatomists, and that their analogies have been mistaken. The attachment of the temporal aponeurosis to them has nothing to do with their stronger or less development. The frontal bone in the fœtus and child to a certain age in uniformly divided into two equal parts by a suture running down mesially; this suture generally disappears with age, but sometimes it does not, and then we have a proper frontal suture; *sutura frontalis*. At other times the mesial part of the bone from the glabelle upwards is elevated into a ridge, continuous with one, or rather occasionally with two, traversing the parietal in the same direction. I have even found that occasionally the mesial frontal ridge shewed slight traces of duality. But be that as it may, it is but a portion of a system of crests developed more or less occasionally in individual crania—analogous to what we find in the lower animals, and particularly and especially in some quadrumana. The German anatomists speak of this mesial frontal crest as an elevation shaped like an ass's back, but this diverting comparison gives no insight into its nature.

Whilst the exterior of the frontal bone shows, generally, a comparative smoothness, it is sufficiently remarkable how frequently an opposite character prevails on that surface of the frontal bone which faces the brain. I do not allude merely to those elevations and depressions usually seen on the surface of the vertical and horizontal portions corresponding, as is said, to similar elevations and depressions of the brain; I allude more especially to those specimens sufficiently numerous and found most frequently, I think, in women, of a great increase in thickness of the skull or the inner surface of the vertical portion of the os frontis, by a successive deposition of osseous laminæ, often exceedingly rough and laid down irregularly. I have heard it said, that this singular appearance is found mostly in women who have had children, and that a layer of bone is laid down during each pregnancy. But it has not been remarked that women became more stupid on this account.

The vertical plate of the os frontis occasionally overlaps the parietal bones, or is overlapped by them. This very rare occurrence I have seen well marked only once, and I here subjoin a drawing of the preparation as seen in profile; this very valuable specimen is now in the museum of Dr. John Argyle Robertson, who has kindly permitted me to make use of the case.

The particulars of this case are extremely instructive; they are briefly as follows: A labouring man fell from a height on his head, and from that moment became insensible; having been brought into the Royal Infirmary, a depression was felt behind or in the neighbourhood of the frontal parietal suture, and a depression of bone being suspected, it was resolved, or at least proposed to apply the trephine. Before the visit, however, of next day, the man died; dissection revealed an extensive fracture across the base of the skull, but that which had been taken for a depression was merely an overlapping of the frontal and parietal bones. This overlapping of the bones of the cranium is a singular circumstance in their physiological history; we shall afterwards advert to it more especially when speaking of the occipital, the squamous plate of which is the bone which of all others overlaps most frequently and sometimes to a great extent. The facts I have collected in regard to this overlapping of the bones of the cranium are, that it rarely occurs in the dark races of men, being, in fact, chiefly confined to the European, and found most frequently in the Saxon race. The theory of its explanation offered by the German anatomists and flowing from the doctrine of analogies is, that it is merely an abnormal repetition in man of a structure which is normal in the lower animals and in the human fœtus. This, I myself believe to be the true explanation, although I have looked for it in vain in many crania of the higher orders of the vertebrata and mammalia. The cranial bones of the human fœtus are moveable, may readily be made to overlap each other: in making preparations of these, the brain being removed, they may be observed frequently to dry in this way, thus imitating on a small scale what we afterwards find occasionally to happen in the adult cranium.

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.

Physician to the Birmingham General Dispensary; formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c, &c.

(Continued from page 7)

Morgagni ennumerates many varieties of sputum: —Sputa with less analytical precision, (1), copiosa, xiii, 3; xvii, 10, 14; xviii, 17; xx, 11, 20, 22, 24, 26, 39; xxii, 8, 10, 14; lxiv, 12. Sputa serosa, xvii, 6: xx, 26; xxii, 10. Sputa viscida, lenta, tenacia, xx, 26; xlii, 2. Sputa crassa, xvii, 10, 14; xviii, 25, 34; xx, 9, 39, 49; xxi, 19, 30; xxii, 14; xxxv, 16. Sputa crassa, et pravi saporis, lxv, 3. Sputa catarrhalia, xx, 32, 39; xxxvi, 4; xxxviii, 6, 12, 13; xl, 23; l, 4; lxviii, 12. Sputa catarrhalia cruenta, xx, 32. Sputa cruenta, xvi, 28; xviii, 30, 39, 43, 57; xx, 3, 28, 33; xxi, 19, 35, 44; xxxv, 16; liii, 14, 29; liv, 39; lxv, 19; lxx, 7. Sputa cruenta viscida, xxi, 34. Sputa cruenta, spumosa, xxxvi, 17. Sputa cruenta cinerea; liii, 29. Sputa rosca spumosa, xx, 17. Sputa ex rubro flava, xiii, 3. Sputa flava, xx, 9, 39. Sputa ex flavo variegata, spumosa, xxi, 30. Sputa varie colorata, xxii, 24. Sputa ad viride inclinantia, xx, 3. Sputa cinerea et livida, xxi, 32; lxiv, 5. Sputa livida fluida, xx, 9. Sputa flava fluida, xxi, 30. Sputa rufa fluida, xvi, 36. Sputa nigra, xxi, 32. Sputa alba non concocta, xxi, 44. Sputa puriformia, lxiv, 12. Sputa quasi purulenta, xvii, 25; xviii, 34, 35. Sputa quasi purulenta, et interdum cruenta, xvi, 19. Sputa purulenta et cruenta, xv, 15. Sputa purulenta et rotunda, xx, 61. Sputa purulenta, xx, 5; xxi, 32; xxii. 6, 11, 14, 15, 16, 24; li, 18, 19, 20; liv. 6; lviii, 13. Sputa grave olentia, xx, 26; xxi, 32. Sputa materiæ illaudabilis, xxvi, 33. Sputa materiæ, sanguine nonnihil tinctæ, lii, 15. Sputa gelatinæ subrubræ, xvii, 21. Sputa particularum albarum quasi polyposarum, xxi, 19. Sputa salivæ erodentis, xviii, 17.

Sauvages, under the term anacatharsis, which he borrows from Hippocrates and Galen, recognizes several varieties of sputum. Anacatharsis biliosa, or choleptysis; anacatharsis azurea; anacatharsis phthisica; anacatharsis a vomica; anacatharsis puriformis; (tussis purulenta, Stahl.) anacatharsis asthmatica (asthma humidum); sputatio arthritica.(2)

Van Swieten treats of the following, and chiefly in connexion with pneumonia, pleuropneumonia, and pleuritis.(3) Sputum flavum, sincerum, viscidum, rotundum, vol. 2, p. 743-4. Sputum biliosum, valde cruentum, 2, 772. Sputum album, rotundum, 2, 773. Sputum spumosum, 2, 773. Sputum fuscum, amœrcosum, nigrum, 2, 794. Sputa a quibus supprimantur, 2, 794. Sputa purulenta subsanguinea, 3, 60. Sputum sanguinis, 4, 3. Sputum dulce (phthisis) 4, 71. Sputa insipida, 4, 72.

In 1809, Dr. Pearson published (4) the result of his inquiries concerning expectorated matter, of which these are a summary:—

"1.—The jelly-like, semi-transparent kind, of a bluish hue, excreted in a healthy state.

2.—The thin mucilage-like transparent matter, so copiously expectorated in bronchial catarrhs.

3.—The thick opaque straw-coloured, or white and very tenacious matter, coughed up in a great variety of bronchial and pulmonary affections, especially in that of tubercles.

4.—Puriform matter, secreted without any division of continuity, or breach of surface of the bronchial membrane, very commonly occurring in pulmonary consumption.

5.—The masses which consists of opaque viscid masses, together with transparent fluid; or the second sort above stated, with nodules of the third or fourth kind.

6.—Pus from the vomicæ of tubercles.

7.—Pus from vomicæ by simple inflammation of the lungs, and without tubercles."

In 1821, Andral published his Thesis, "Recherches sur L'Expectoration dans les differentes maladies de poitrine." In this work he rather treats of chest diseases as being distinguished by certain forms of sputa, than of the varieties of sputa which distinguish certain forms of chest disease. There is, consequently, no classification of expectorated matter. He merely observes, of the tracheal and bronchial mucous membrane,—"Ainsi selon la stimulation particuliere qui lui est imprimée, elle secrete un mucus visqueux, transparent et sanguinolent dans la pneumonie; limpide et incolore dans le catarrhe aigu; opaque et puriforme dans le catarrhe chronique; se concretent en fausse membrane dans le croup, &c." —p. 9.

In a communication made by Mr. Brett, of Liverpool, to the British Association at its annual meeting in 1837, the chemical habitudes and composition of different sputa are treated in detail, but without any attempt at classification.

"From the chemical examination of sputa," says Mr. Brett, "it is deduced that they differ from each other, in the proportion of soluble albumen capable of coagulation by heat, which they contain, as also in the amount of fixed or non-volatile saline matters. That form of expectoration met with in pituitous catarrh does not contain any free albumen capable of coagulation by heat, and for equal weight, less saline matter than anyother form of sputum; the solid matter also amounts to very little more than that met with in ordinary saliva, and sometimes even less, and although, for equal weight it contains less solid and saline matter than any other form of sputum, yet, for equal weight of dried extract, it contains more than any other form of expectorated matter. The sputa in chronic bronchitis differ from the last noticed, principally in containing a small quantity of free albumen, which heat coagulates; in the larger quantity of solid matter contained in it, being double that found in the sputum of pituitous catarrh; in the quantity of saline matter being less in proportion to the solid contents, although for equal weights of the two forms of expectoration, the difference is not considerable. In acute bronchitis, the albuminous matter found in the expectoration, probably arises from the presence of a muco-purulent secretion poured out by the inflamed bronchial membrane. Sputum precisely like the chronic bronchitic variety, occurs also in the different, but more especially in the early or middle stages of phthisis, with or without an admixture of softened tuberculous matter; in no disease, however, is free albumen, capable of coagulation by heat, met with in such abundance as in the latter stages of phthisis; the absence of such considerable albuminous impregnat on cannot, however, be taken as clear evidence of the non-existence of phthisical disease, for the latter may exist, and the expectoration still be of precisely the same character as that met with in chronic, or even acute bronchitis; when on the other hand, a large quantity of coagulable albumen is present, the existence of phthisis may be strongly suspected, a small quantity of the albuminous principle only being common to phthisis as well as simple bronchial affections unassociated with tuberculous disease. Genuine pneumonic expectoration always contains coagulable albumen which appears to be derived from the blood to which this form of sputum owes its peculiar colour. The quantity of solid matter is considerably greater than in any of the preceding forms of expectoration, amounting to more than double that met with in the chronic bronchitic variety.

(4.) Philosophical Transactions for 1809. Part 2, p. 313-344.

The extremely tenacious character of genuine pneumonic sputum is probably depending upon the existence of a very tough form of mucus resulting from a very active inflammatory condition of the smaller bronchial tubes. In phthisis, the expectoration varies much according to the stage of the disease, and it is only for the most part in the latter stages that it is generally found to differ in a marked manner, both as to its physical appearance and chemical habitudes from all other forms of sputa. In the earlier stages of the disease, it may be precisely the same as that met with in pituitous catarrh, or other decided bronchitic affections; in the latter stages, however, it will almost always be found at some time or other to contain large quantities of coagulable albumen, as well as the same principle in the solid form; so that in some instances it scarcely differs in appearance from ordinary pus, of which, in fact, it mainly consists. The origin of the puriform matter in phthisis is probably from different sources; 1st, from the perfect softening down or fluidification of tubercular deposits; 2ndly, a secretion from the bronchial membrane; and 3rdly, from the secreting lining membrane of tubercular cavities. One thousand grains of phthisical expectoration of a well-marked purulent character, being so diffluent that it might be poured *guttatim* from one vessel to another, possessing a distinct greenish tinge, were analysed with the following results:—

Water	967·300
Albuminous matter, with a little mucus	17·387
Animal matter soluble in alcohol, consisting of fatty matter, and a little extractive	6·177
Animal extract soluble in water	5·840
Salines, consisting of alkaline chlorides, sulphates, and phosphates, earthy phosphatic salts, and oxide of iron. The base of the alkaline salts was chiefly soda; a little potass was, nevertheless, present	1·813
Loss	1·483
	1000·000

The above exhibits a striking similarity between the puriform variety of phthisical expectoration, and actual pus. In both is an abundance of coagulable albumen, in both solid albumen, in both are extractive matters, both contain fatty matter, the same or nearly the same alkaline and earthy salts; and lastly, in both fluids a notable quantity of oxide of iron is found. Phthisical sputa, late in the disease especially, contain a considerable quantity of fatty matter soluble in alcohol and ether, and requiring a higher temperature for its fusion than ordinary fatty matters; other forms of expectoration, particularly that of the chronic bronchitic kind, contain the same substance, but never in such quantity as in genuine phthisical sputa.

That crude tubercular deposit is capable of being converted by the process of softening or fluidification into pus, is rendered highly probable from the chemical nature of hard tubercles, as well as that of the same deposit in the most complete state of softening. From a comparative chemical examination of crude tubercle and ordinary fibrine, as well as from the action of reagents on softened tubercular matter, the following is deduced:—1st, that crude tubercles, as met with in incipient phthisis, do not differ chemically from fibrine or solid albumen; 2ndly, that softened tuberculous matter differs not in its chemical habitudes from ordinary purulent matter."(5)

Mr. Bishop, well known by his paper on Motion, in the "Cyclopædia of Anatomy and Physiology," has just received from the French Academy of Sciences 1,000 francs for his paper on "The Human Voice," and another sum of 1,000 francs for a paper on the "Comparative Physiology of the Human Voice."

Sir James Graham has written to say that Graduates of any Scotch University may register as physicians without joining any College of Physicians.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

In order to make out the essential pathology of apoplexy, we must make a comparison of its morbid anatomy. In some cases, on examination after death, of persons who have died of apoplexy, no morbid condition is found; and this is the case where apoplexy is caused by narcotic poisons, there being apoplectic stupor in connexion with it. For example, where alcoholic liquors are taken in excess, the person drinking so great a quantity may fall down in a state of coma and die: opium in some degree will produce a similar effect, and aconite is said to cause death in the same way. Suppression of the excretions sometimes is accompanied by symptoms of coma, and a state of apoplexy: sometimes mental shocks have been known to produce it without leaving any appearances after death. Electricity seems to have a similar effect; the injury done by this is an irrecoverable one to the nervous system. Apoplexy caused by opium is rather complex: where it proves fatal by causing asphyxia—and here there is not nervous apoplexy alone, but congestion of the vessels of the brain—it approaches to the character of congestive apoplexy. Whenever, in cases of apoplexy, there are no traces of lesion found after death, it is called nervous apoplexy, something injuring the nervous function directly, without causing any material change in the condition of the blood vessels, or any discoverable change in their structure. In the second variety of congestive apoplexy, all the vessels of the encephalon are extremely large, and the vessels of the scalp are often, also enlarged in a similar manner. This is indicated before death by the red and flushed appearance of the face. With this distension of the vessels there may be some serous effusion; in fact it may end in serous effusion. Now this congestive apoplexy may be produced by the various causes of mechanical congestion, as well as the other causes which I have mentioned under the head of General Pathology. For instance, from obstruction to the return of blood through the veins, as in the case of disease of the heart, either by tumours pressing on them, or by aneurism. Cupping and bleeding have been known to produce congestive apoplexy; and it has been caused by intense cold, in which case the brain is generally engorged with blood. It is also apt to occur in cases of partial congestion from a languid circulation and very cold extremities; and general plethora may lead to it. It affects persons predisposed to affections of the brain more than the vessels of any other parts. It has been remarked by Andral and others, that a deficiency of fibrine and an excess of the red particles seem peculiarly to predispose to apoplexy.

Now the congestive form of this disease is often preceded by symptoms of congestion, either general or partial fulness. The symptoms may be comparatively slight, until, from some exciting causes, straining, stooping, or any obstruction, the congestion is suddenly augmented, and what is called a *blood stroke* generally takes place in the head, the vessels being usually distended. This implies an increased quantity of blood in the head, and no one who seen a case of congestive apoplexy can doubt that there is an increased influx of blood to the head under such circumstances. There has been some dispute about the presence of any quantity of blood in the head at any time, but there are several circumstances that seem to prove that it is capable of holding more blood at one time than at another. It is not true that it is totally inexpansible; it looks very hard, and it is a very tough material; but there is no structure in the body that does not admit of a certain degree of flexion and tension; and though you would be ready at first to say that the power of the blood could not produce any impression on such a firm resisting mass as this, it is not quite accurate. You remember the power of the hydraulic press on a small force, producing an expansion over a comparatively large surface; just so the blood pumped up into the brain in small orifices can expand and increase the distension of the whole head. To give a practical illustration, you know that on straining or stooping, people instinctively put their hands to their heads to hold it, or tie a handkerchief round it to give it resistance. The fact is, the bones of the skull are a little yielding, and the brain will hold more blood at one time than at another; and though the greater part of the skull does resist to a great extent, there are orifices leading from it in which there is no resistance, or but little; accordingly, when the blood accumulates in the head, the pressure, however much resisted on the whole surface of the skull, is not resisted in the *foramina*, and the tendency is to squeeze the matter out of the foramina, and therefore there is a peculiar pressure on the foramina, the medulla spinalis, and the various parts that go out through the base of the skull. Take another case: the quantity of moisture and serum in the encephalon is not always alike; the difference in this respect is sometimes very extraordinary. In general, apoplexy is accompanied with a good deal of humidity. In the next variety, hæmorrhagic apoplexy, you often find, on first looking at the brain, that on the upper surface there is an absence of serum; it is a complete, compact mass, in which the convolutions are compressed together; in the ventricles you find no serum; and remember, the brain is composed of somewhat about nine-tenths of water. This argument will show how the brain will hold more blood at one time than at another. There is another mode in which coma may be produced by apoplexy, that is, the blood may occupy one set of vessels more than another, and whenever that is the case, the circulation will be impeded; although there may not be a great quantity of blood altogether in the whole brain, yet the effect of the distension of some vessels will be to compress the others. Hence, where there is venous distension, there will be comparative compression of the arteries. On the other hand, determination of blood produces, under some circumstances, fits of coma. It is accompanied sometimes by an expanded state of the arteries, and that expansion is greater in proportion than the expansion of the capillaries; and in some cases you will have strong pulsation in the carotids, and the ascending aorta, and the pulse at the wrist will be very weak and feeble, and this irregular distribution of the blood in the very arteries themselves, when acting on the head, may tend to derange the circulation; instead of propelling the blood through the whole of the vessels, it unusually distends some, and cuts off the motion to the others. These considerations, however, wholly fail when applied to medicine. Now, congestive apoplexy, which occurs without any rupture or lesion of the vessels, and substance of the brain, is, of course, of a more favourable character than the hæmorrhagic variety, and sometimes it is at once removed by blood-letting; after twenty or thirty ounces of blood are drawn, the patient gradually recovers consciousness:—this is another proof of actual pressure. But if the apoplectic stroke, even from congestion, be strong and severe, or especially, if it be not soon removed and the patient remain in a state of coma for a considerable time, the blood-letting will not remove the symptoms altogether. There are left after this partial paralysis and epilepsy, and frequently this congestion leads to inflammation, and softening. This is especially apt to occur where the congestion has been induced by exposure to heat. I do not describe serous apoplexy distinct from the present form, because it is apt to be associated with the congestion I have described already, or else with the different cases of chronic hydrocephalus and dropsy. Congestive apoplexy is one of the mildest forms of apoplexy, and occurs in combination with other diseases, constituting coma and fever. In congestive apoplexy the brain is found greatly congested, and this is the cause of the oppression of the functions. The third variety of apoplexy is the hæmorrhagic, and is dependent on an increase of blood, not in the vessels of the brain, but effused into its substance, and on its surface. The exciting causes of this are much the same as

hose of the congestive form. On examination after death, we find when the calvarium is taken off, the brain commonly full and large, and the convolutions flattened and dry; the substance of the brain feels very firm, and is getting rid of a good deal of its liquidity, which may be squeezed out of it, and in various parts of the brain there is found blood usually in clots, and partially liquidated. In case of thundering apoplexy, the sensorial function, and those concerned in the support of life are attacked. Sometimes the effusion is in many parts, and not in a large clot in the manner before described, but forming *punctiform capillary hæmorrhage* as it has been called; hæmorrhage of many vessels at once. The situation of these effusions varies considerably, but the most common situation is the substance of the hemispheres, about the *corpora striata*, and the *optic thalami*. For instance of 386 cases of hæmorrhagic apoplexy, in 292 the clot or effusion was in the substance of the hemispheres, the others on the surface; and of these, 161 were in the corpora striata, and 35 in the optic thalami. Well now, what is the cause of the hæmorrhage? They are circumstances that cause congestion to terminate in that way. Excess of determination of blood, or excess of congestion; where this arises, in some degree the vessels break and give way. In the greater number of cases, this giving way will not take place without disease of the vessels, or of the substance of the brain, or diseased condition of the blood; and accordingly, we find, on examination of the vessels of the brain, in cases of hæmorrhagic apoplexy, atheromatous patches on their coats, or actual ossification, so that they are more fragile than usual, and sometimes they are dilated into little sacs. A case is given by Dr. Thompson, in which a little aneurism was formed in connexion with one of the arteries of the brain. Another circumstance is determination of blood, connected with a too strong ventricle of the heart; and hypertrophy of the left ventricle is found to occur in many cases of hæmorrhagic apoplexy, the force with which the vessels are distended being here exaggerated. This tends not only to increase the force of the determination of the blood to the head, but also to alter the structure of the vessels. There are other diseases—or disease of the substance of the brain—which lead to hæmorrhage. In some cases apoplexy has been preceded by inflammation: phrenitis; and the connexion I have insisted on between determination of the blood in the first stage of inflammation, may be such that the vessels give way. In other cases, it does not take place in connexion with determination of blood, but afterwards, when the brain has been injured or softened by the inflammatory process, which is the result of local inflammation. Partial cerebritis is the common cause of hæmorrhagic apoplexy. Sometimes there is *ramollissement* of the brain preceding the stroke of apoplexy; the brain has not only a clot in it, but a considerable softening around the clot. In many cases it is easy to distinguish the priority of these lesions; the softening bears marks of considerable age, the substance being discoloured to a considerable extent, and altered in appearance; whereas the clot may have been quite recent. No doubt the clot tends to produce inflammation, and the softening may ensue.

There are some differences in the appearance of the clot; the recently effused blood is of a very vivid colour, like fresh blood; but if the clot is old, it becomes lighter and browner in colour, particularly at the surface; there is a sort of cyst round it, whilst the cerebral texture exhibits various appearances betokening inflammation. There is a reddish brownish colour; sometimes yellow softening, interspersed with a little greenish discolouration. Where the mischief has remained long, it leads to softening and atrophy of that portion where the clot is. This shows that hæmorrhagic apoplexy may not be immediately fatal; a sort of healing process may take place after the clot has occurred. In some instances, the clot appears to be organized, forming a sort of tumour, and there is sometimes hardening of the brain. The symptoms of hæmorrhagic apoplexy may be sudden; sudden coma, without prior symptoms, especially where a very plethoric state has preceded it. But sometimes it is preceded by symptoms of partial softening. The immediate symptoms of hæmorrhagic apoplexy are of two kinds: there may be sudden production of coma like congestive apoplexy; stertorous breathing, a slow full pulse, and suffused face. Sometimes the symptoms are more those of syncope: the person attacked falls down, the face is extremely pallid, the breathing may be stertorous, with the pulse irregular; instead of slow and full, it is weak and intermitting. These are the cases in which the patient dies of syncope; the mischief obviously arising from the injury done to the brain alone, and directly affecting the heart's action. If pressure was produced on the whole brain at once, death would be caused by coma. Sometimes the symptoms are those of coma at first, and then suddenly in the midst of those, there occurs syncope. This is where the hæmorrhage takes place gradually.

Now after hæmorrhagic apoplexy you may well suppose there is much more likelihood for the production of paralysis. Here is an attack of apoplexy, depending on external injury from a depressed portion of the skull. The effects are varied, according to the pressure, and they may be complicated with hæmorrhage or with mechanical mischief done to the brain. Besides the exciting causes of apoplexy which I have mentioned, there are others that predispose to apoplexy. Hypertrophy of the left ventricle, for example, obesity, stoppage of the evacuations, diminution of the excretions, and chronic degeneration of the kidneys.

The diagnosis of apoplexy is to be founded chiefly on the state of the circulation, and the complete abolition of the functions, the congested state of the brain, and the slow character of the pulse on the one side, or its irregularity accompanied with pallor of the face on the other side, and by these conditions being accompanied by stertorous breathing, often slow and irregular, and at long intervals. Sudden loss of consciousness is another thing to be considered, distinguishing this from intoxication, which in a very high degree resembles apoplexy. The state of the pupils is not much to be depended on. The prognosis is to be determined by the duration of the coma; if it has lasted long and the breathing become stertorous, and the circulation affected more and more, there is little hope of recovery. If the apoplexy has fully passed off and consciousness begins to return, the prognosis may be formed by the amount of paralysis and injury left. It is not of the to be relieved by depletion or other remedies, if there is much injury. When there is disease of the other parts of the body, the prognosis is worse. The treatment should be regulated by a fair view of the cause, the previous habits and condition of the subject, and the present state of the individual. Bleeding is supposed to be one great remedy for apoplexy, but it is sometimes detrimental at the first occurrence of the paroxysm. If the pulse is weak and irregular, and there is stertorous breathing, blood-letting may kill him; his state is that of extreme depression, and he is dying under these circumstances, from syncope and coma. It may be necessary sometimes to give stimulants, but in that you must be guided by the state of the pulse and the aspect of the countenance. Where the pulse is full and the countenance congested, no doubt bleeding freely, until an impression is produced, and the pulse falls and is more frequent, is beneficial. It is remarkable what a large loss of blood patients who have congestive apoplexy will bear, and from 40 to 50 ounces may be drawn without weakening the pulse. Blood-letting may be carried on until symptoms of consciousness return. Purgatives, calomel and croton oil, are useful. Cold water thrown on the head is a useful expedient, together with the measures I have mentioned. There is great danger in congestive apoplexy, where there is no syncope, arising from the state of the respiration: although the medulla oblongata is mostly oppressed by the disease, its action may be excited by operating on the accessary nerves, connected with the respiratory apparatus; dashing cold water on the head has the effect of relieving these symptoms. The state of the countenance is to be watched, and, if necessary, the remedies are to be given again and again. After blood-letting, pallidity may come on, and even in a short time after blood-letting, it may be necessary to give stimulants. It is of great consequence to distinguish between the states of oppression and depression. After the immediate symptoms of apoplexy are removed, there will occur hemiplegia, which is another evil. Inflammation from re-action, too, is exceedingly apt to arise after apoplexy. This occurs about the eighth day, and the case must be watched, and the treatment kept up to prevent it. Antiphlogistics and mercury should be given, cold should be applied to the head, if it is at all warm, and cupping, blisters, and so forth should be employed. These remedies are to be continued more or less until there is relief, as paralysis and hemiplegia are apt to arise. A free action of the bowels should be secured, the living moderate, without actually starving, particularly in old people, avoiding all excitement of body or mind, and keeping the head wrapped up. These are the chief means by which a cure is calculated upon. Returns of apoplexy are to be prevented by cupping and leeching the neighbourhood of the head and back of the neck, keeping down the action of the heart by digitalis and medicines acting on the secretions. A seton may be used. In gouty persons colchicum is useful.

MATERIA MEDICA.

Some Account of the Medicinal Properties of the expressed Juice of Missletoe-Berries in the Treatmen[t] and Cure of Facial Neuralgia, and Affection[s] Analogous in their Nature to Tic Douloureux.

By R. W. Hardy, Esq. Lieut. R.N., Bath.

(Read before the Royal Medico-Botanical Society.)

Few disorders are more painful to witness i[n] others or to experience in ourselves than tha[t] which passes under the general name of *ti[c] douloureux*, in whatever situation of the body it ma[y] show itself. It is said to be of much more frequen[t] occurrence latterly than in former years; and i[f] this be true, a safe remedy is the more needed. The immediate causes which conduce to th[e] disease are not probably more numerous tha[n] heretofore: irritation of the *primæ viæ*, vitiate[d] secretions, and various constitutional disturbance[s] are among the most active; and the effect produce[d] is usually distant from the seat of the primar[y] disease.

But the origin of the morbid phenomena which in cases of *tic douloureux*, are present to th[e] senses of the patient, are not in many case[s] either so deeply-seated or so distant as might b[e] supposed: an inflamed gland or small lymphati[c] vessel, or the irritation produced on a nerv[e] by a diseased or decayed tooth, are cause[s] sufficient to account for sufferings experienced i[n] the face or other part.

I need not enumerate the remedies, some toni[c] some alterative, which it has been though[t] expedient to prescribe for the eradication of thi[s] formidable enemy; neither need it be mentione[d] that they generally are little better than palliative[s]. The object therefore which I have now in view i[s] to propose a *new remedy* which *in the majority* [of] *cases*, will moderate or cure the sympatheti[c] affection, and I trust it will recommend itself [to] the favour of the Council, and of the Professi[on] by its simplicity and its cheapness, the ease wit[h] which it can be applied to any part, and abo[ve] all, by its safety. It consists of merely a plaste[r] composed of *bird-lime* and yellow wax, which is [to] be put upon the part sensibly affected. *The reli[ef] obtained is almost simultaneous with the application [of] the plaster.*

Let it not however be supposed that I wish [to] impose upon the most credulous person the beli[ef] that the mere application of a plaster is sufficie[nt] for the removal of organic disease. It would [be] indeed hopeless to expect that a disordered functio[n,] an affection of the brain or spinal nerves, morb[id] irritation of the gastric and intestinal nerves, [or] any disease of structure can be benefited by [it]. Nevertheless, my experience warrants me [in] asserting that, let the primary cause be what [it] may, the secondary or sympathetic affection w[ill] *in a majority of cases*, be effectually, and, in ma[ny]

even, permanently relieved by it; and this, too, without aggravating the real disease.

It is now fit that I should give the *directions for the preparation of the plaster.*

Expressed and concentrated juice of missletoe-berry, one part; yellow wax, two parts.

Melt the wax in a large iron vessel, and add the *bird-lime* in small quantities at a time, till both are combined. Then run the fluid mixture into moulds of any convenient size.

Mem.—As there is between wax and bird-lime no common bond of attraction, and as they cannot be made to unite without considerable difficulty, the specific gravity of the two bodies being different, it is necessary, for this purpose, to attend to the following RULES.

First, put a small piece of wax into the melting-cup, place it over the fire, and when dissolved, add to it a very small quantity of the *bird-lime*, at the same time withdrawing the cup from the fire, stirring the mixture rapidly with an iron rod, that the moisture of the *bird-lime* may slowly evaporate. If this operation is performed too rapidly, or there is too much the *bird-lime* added at a time, the expansion of the steam raised by the heat will overflow the contents of the vessel. As soon as the vapour ceases to rise, replace the pot on the fire, and add more wax, and then more *bird-lime*, in manner as before, and so on alternately till all be dissolved. The pot must now be continued on the fire, and the mixture kept stirred till the two substances be thoroughly incorporated, the one with the other, which will take about one hour to do; and they will not afterwards separate.

Before running the liquid mass into a cup, it should be made to pass through a fine sieve in order to separate particles of sand and other impurities usually contained in the *bird-lime* of commerce. This done, the plaster is fit for use, and may be spread on linen, cloth or paper, secundum artem.

Directions for using the Missletoe-berry plaster.

Take a piece of spread plaster of any required size, as large as half a crown, or larger, and place it immediately over the spot where the pain is felt, whether in the face, the eye or elsewhere, and confine it there with a bandage or other cloth; for otherwise, as it will not adhere to the flesh, owing to the wax, it will presently fall off. It must be kept on till the pain has subsided, which will be in a few minutes. However, for precaution sake, lest the pain should relapse, I generally recommend that the plaster be kept on a whole day, and even longer in very bad cases.

As soon as the plaster is removed, it is necessary that the patient rub, with the finger's point, a very little oil of sweet almonds on the place that had been covered, as a protection from cold. And further, if business require him to go out of doors before the pain ceases, and he object to have his face bandaged up, the plaster may be placed on the upper portion of the large lateral muscle in the neck, and there worn night and day; or it may even be put over the first joints of the spine, and there worn as long as may be desired.

Absurd as these directions may appear, the practitioner who shall carry them out, will, in three cases out of five meet with the reward to his own feelings which success in a laudable object never fails to bring.

But the dry carbonised powder of the juice of the missletoe-berry or bird-lime may be employed alone, by rubbing it on the part affected, either with the finger, or, the pressure of that member being too great for endurance on so tender a part, with a camel hair pencil. Some patients however, cannot bear even this slight friction, on which account I find it best to give the plaster prepared according to the above formula. For wax, as being without any irritating quality, is free from the objection which attaches to many other substances.

Permit me to say, that many valuable vegetable substances lose their efficacious property by being combined in the form of plaster with *resinous* bodies, which are all more or less irritants, and especially unfit for nervous affections, such as those now under consideration. For it must be observed, that such substances stop up the pores of the skin that their orifices are prevented from discharging the insensible perspiration. In general sufficient attention is not given to this matter; and I have no doubt that it will be found that *people are more or less sensible to change of weather) from moist to dry, from the more or less spongy state of the skin, and not to a peculiar nervous temperament, as is usually thought.*

Independently of what has been said of the unsuitableness of *resinous* substances except under peculiar circumstances, for external applications, it is right to add that thick plasters cannot in general be removed without tearing away a portion of the skin, thereby leaving the orifices of innumerable small capillary vessels exposed to the injurious action of the atmosphere—a circumstance that must be highly improper.

No evil of this kind results from the plaster I have recommended, seeing that while the cutis is preserved in its integrity, the exhalants, though slightly impeded, perhaps perform their functions with sufficient activity.

One of the most singular features of the missletoe-berry plaster is, that neither time, nor climate, nor repetition in use diminishes its effective and sanative properties. The same that has been used before may be employed again and again with perfect confidence and advantage, until its substance be entirely worn away by frequent repetition—this fact is not less startling, than the analogous one of the durability of power in glass of antimony.

In proposing a new remedy, it is usual to offer an opinion as to the *modus operandi*; but herein I feel my own incompetency to make a suggestion. I will therefore only describe a few of the sensible effects which patients have experienced from its employment in cases of *tic douloureux.*

Some have complained of a feeling of extraordinary heat after having the plaster put on; and at the end of the third day, have been obliged to remove it on this account, expecting to find a blister raised beneath it: and were not a little surprised that there was not even the slightest appearance of redness. This gave them courage to re-apply the plaster, and after a short time they were relieved of pain. In other instances, especially when the plaster has been put upon the face or temple, or even the neck or spine, they have almost immediately felt a sensation of a dreamy fluttering and delightful lulling of the senses, spreading and extending like a wave over the whole head, and, without inducing sleep, creating a repose of the whole system, and taking away pain. These sensations are more frequently experienced when the pain has been felt in the throat and nose, or on the tongue.

It would be absurd, as it would be unphilosophical, to assert, that the same benefit would result to each patient from the use of the missletoe-berry plaster; but herein, as in other cases, the exception establishes the rule. I can, however, confidently assert, that no case has come under my observation in which *some* benefit has not been derived from it, and not one in which injury has resulted.

Before closing these observations, I beg to remark that, like most other vegetable substances, the missletoe is capable of yielding an alkaline body, which readily forms a salt with sulphuric, and some other acids; and it is highly probable that it may be found, on a careful analysis, (which I hope will be undertaken at the desire of the Council) to be a distinct body, *sui generis*; and that it will prove highly beneficial, when given internally, in many nervous disorders which have hitherto baffled the Physician's skill.

In a letter which was read afterwards, Mr. Hardy mentioned having obtained the active principle of the bark of the ilex aquifolium by maceration in rain-water and subsequent evaporation.

CASE OF RUPTURE OF THE HEART.

(To the Editor of the Medical Times.)

SIR.—I am desirous to record the following case of rupture of the heart, if you think it deserving a place in your columns, not only on account of the comparative rarity of this mode of sudden death, but because many more cases are required in order to determine the relative frequency of its predisposing causes.

On the 17th of March, an old woman, nam[e] and age unknown, was seen running along th[e] Strand in a westerly direction, when she fe[ll] against the gates of King's College. She re[-]mained motionless, froth issued from her mouth and one gentleman thought the pulse was per[-]ceptible. She was immediately removed on [a] stretcher to the hospital. When first seen her the body was still warm, but no pulse nor breathin[g] could be distinguished; the face was pale, an[d] the lips and tongue were bloodless; the pupils wer[e] neither contracted nor dilated. An incised woun[d] of the scalp, an inch in length, was found over th[e] posterior portion of the left parietal bone; th[e] periosteum was also divided, but the bone did no[t] appear to have been injured; about half a te[a-]spoonful of blood, only, had been lost; there wa[s] a pin in the hair and cap immediately over th[e] wound.

About forty-eight hours after death, Mr. Dun[-]can, the house surgeon, and myself and severa[l] others, made a *post mortem* examination of th[e] body. No fracture of the base of the cranium could be found; the brain was firm, and, in ever[y] respect healthy; there was no vascular engorgemen[t] and no ecchymosis, either coresponding to th[e] external wound, or on the opposite surface of th[e] brain. On opening the chest, some pleuritic ad[-]hesions were discovered on the right side, and [a] few tubercular deposits in each lung; there wa[s] an old adhesion, about the size of a sixpence, be[-]tween the left pleura and the pericardium. Th[e] pericardium was distended with a large clot of blac[k] blood, at least four ounces in quantity; the hear[t] was collapsed and entirely surrounded with [a] clot; both its ventricles were empty, but th[e] auricles contained small clots of blood. On th[e] posterior surface of the left ventricle, not quit[e] half an inch from the septum, about the middl[e] there was a rough aperture, about a third of a[n] inch in length; there was slight ecchymosis aroun[d] the lips of this aperture, and a black spot on th[e] surface of the ventricle, about a quarter of a[n] inch from it; on examining with a probe, th[e] aperture was found to communicate with the lef[t] ventricle, passing obliquely upwards and toward[s] the left, and opening internally behind the pos[-]terior fold of the mitral valve; no ruptured orific[e] could be seen internally, but the probe could b[e] made to pass readily through several of the open[-]ings between the columnæ carneæ, no ulceration of the internal coat of the ventricle could be dis[-]covered. The mitral valve and aortic semilunar valves appeared healthy, excepting a small cartilaginous thickening on one semilunar valve; the aorta was very large, and dilated on its convexity; there were numerous atheromatous deposits around that portion where the great vessels are given off, and there the structure was so much injured as to allow the artery to be torn by very slight force. The muscular structure of the heart appeared to be softer than usual; the entire surface of the right ventricle was covered with fat, which, towards the auriculo-ventricular septum, was almost half an inch in thickness. The left coronary artery was completely ossified.

On referring to the articles on Diseases of the Heart by Dr. Joy in the Library of Medicine, edited by Dr. Tweedie, this case, interesting at first from its novelty, speedily became much more so; and it is with the hope of assisting to determine questions not yet settled, that I wish to add a few remarks on the comparison of this case with the statements there made.

There are present, more or less strongly marked, four of the predisposing conditions of rupture of the heart, enumerated in the work just mentioned; softening of the muscular structure, excess of fat, aortic obstruction, hæmorrhagic effusion, or apoplexy of the heart. The increased action of the heart produced by running, or even by the fall itself, supposing that to have been the result of accident merely, was the immediate determining cause. There was ice on the ground at the time of the fall, but the previous extensive disease of the heart and large vessels, allows of no hesitation in considering the rupture to have been spontaneous, and not the result of direct violence. In this respect, there is no deviation from the general rule that, "this lesion, when occurring spontaneously,

has been observed, in a great majority of cases, in the left ventricle." The seat of the rupture, too,—the middle, and not the apex of the ventricle,—confirms the opinions of M. M. Andral and Ollivier as opposed to that of Dr. Townsend.

It is important to remark that there was no ulceration present, which is one of the causes of rupture, and, according to Laennec, "by much the most usual one." The softened condition of the muscular structure of the heart was the only cause that required any nice discrimination in the examination, but the excess of fat present, which ordinarily much reduces "the thickness and firmness" of the heart, gives a degree of certainty to the sense of touch in this case which it would not otherwise possess. But, perhaps, the most efficient of the predisposing causes was the existence of apoplexy of the heart; one spot of ecchymosis was clearly seen, and most probably the rupture itself took place in the very seat of a previous hæmorrhagic effusion. Whether, however, there was more ecchymosis around the rupture, than could have taken place after its formation with so rapid a termination of life, cannot be authoritatively determined. I cannot conclude better than by quoting in full, one paragraph from the excellent articles that have furnished the substance of the above remarks. "The heart is occasionally the subject of *hemorrhagic effusion*, either in the form of patches or petechiæ, on one or both of its surfaces, as has sometimes been observed both in land and sea scurvy, and in putrid fevers; or blood may be poured out in larger quantities, and either infiltrated into the very substance of the organ, or collected into a factitious cavity formed by the separation and laceration of its fibres, constituting the disease spoken of by some authors, under the title of *apoplexy of the heart*. Cruveilhier, who has seen many instances of it, believes it to be much more often than inflammation and ulceration, the cause of rupture of the heart. Hitherto, it has only been observed in the left ventricle, and generally in connection with hypertrophy."

I am, Sir, your obedient servant,
HENRY BROWNE, M. B., M. R. C. S. L.
Physician's Assistant to K. C. H.

RESUSCITATION OF STILL-BORN INFANTS.

(To the Editor of the Medical Times.)

Sir,—As your correspondent, to whom Dr. Guy alludes, (page 397 of the last volume) permit me to offer to that gentleman, and his coadjutor, Dr. Farre, my thanks for the attention they have given the subject, and the manner in which they have presented it to the profession.

It was with no vain curiosity, but from a sincere desire to receive information, that I put the question;—What is the best mode of practising inflation in the still-born infant? Whether viewed in reference to the anxious feelings of the fond and suffering mother, or to the influence which the individual may exert on the future fortunes of the world, the subject is worth more attention than professional men have as yet given it. Many, I know, seldom make any effort to resuscitate the still-born child; not from any Malthusian prejudice, nor from any lack of the best feelings of human nature, but rather from a prevailing conviction that all efforts will be unavailing. But in all cases where there is not indubitable evidence that the child has been dead for some time, endeavours to resuscitate it should be made, and continued for at least twenty minutes.

I am disposed fully to appreciate and practice the preliminary treatment, and the manipulating command of the chest and glottis which Dr. Farre recommends; but I must demur to the use of the operator's mouth and breath, and do think that it is very objectionable to use deteriorated air when pure may be obtained. Dr. Farre objects to the use of the tube because "the air entering more slowly, becomes deteriorated by being delayed in the lungs of the operator longer;" he thus disapproves of "the deep inspiration," and thinks "if the air is rapidly inhaled, and again quickly expelled into the lungs of the infant at short intervals, quite enough of *pure* air is contained in the portion thrown in to restore animation if other things are favourable." This is very doubtful. I believe that the power of the larynx and bronchial tubes upon the air is more essentially involuntary than that of the pharynx upon the morsel of food submitted to its grasp. Add to this consideration, the law of the diffusion of gases, the permeability of tissues, the suction power of the lungs assisted by the diaphragm and intercostal muscles, and it will be difficult not to conclude, that the successive small volumes of inspired air are as completely changed, as the larger volume of a deep inspiration. Let an individual make rapid inspirations, and he will be conscious that the air passes the larynx, and then—whether we adopt the opinion propounded by Black and Lavoisier, that the formation of carbonic acid takes place in the lungs themselves, owing to the contact of the oxygen of the inspired air with the blood contained in the capillaries; or that of M. Magnus, who supposes that the oxygen is merely absorbed there, the chemical change taking place in the course of the general circulation, and that its products are given off from the lungs:—we know that no part of the oxygen remains; but it is given out again in the form of carbon or of hydrogen.

Blumenbach says "however pure may be the air entering the lungs it *instantly* undergoes remarkable changes by which it is contaminated and rendered unfit for another inspiration unless it is renewed."

There is no doubt that carbonic acid in large proportion is eliminated from the lungs. Davy states that a man expires 13 cubic inches of it in one minute.

Instead then of there being "quite enough of pure air," or of its essential constituent oxygen, "in the air rapidly inhaled and again quickly expelled," I believe there is none, and if so, it would possibly be better to use carbonic acid undiluted, than diluted and insidious:—the former might produce such a painful impression as to arouse the dormant action of the lungs: the latter is known to produce depressing and soporific effects. But we should always if possible choose that stimulus, to receive whose action the vital powers are naturally adapted and intended. This is obviously *atmospheric air*.

The objection Dr. Farre makes is scarcely tenable. It may be very much modified by taking care that the particles of air are not rapidly propelled—but, as the ordinary cause of the first inspiration is attributed by physiologists to the novel impression of *cool* air upon the external surface—why should it not be as efficacious when brought to bear upon the internal surface? Especially is the objection obviated when we remember the chemical axiom that in whatever way carbon may combine with oxygen, the act of combination cannot take place without the disengagement of heat. It is a matter of indifference whether the combination take place rapidly or slowly, at a high or at a low temperature, the amount of heat liberated is a constant quantity.

But if requisite, by dipping the pipe of the bellows in heated water, a degree of warmth may be communicated to the air as it passes out, and the temperature of the child may be kept up by its being "placed in a pan or tub of warm water, immersed to the shoulders."

As to the delay and inconvenience attendant on the substitution of the bellows for the mouth:—the accoucheur when he has reason to anticipate a still-birth ought to have warm water in readiness, the bellows can be as easily at hand; few families are without such a wasteful household article, or it can be obtained of a neighbour, or it may be a question whether the practitioner ought not to carry with him a suitable instrument. Most certainly it will be found to be more useful and less dangerous than some of those which are too frequently found in his pocket.

After trying the ordinary simple means and finding them unsuccessful, I should place the child in warm water, command the chest and glottis in the manner so plainly explained by Dr. Farre, and having placed the nozzle of the bellows or other instrument in the mouth of the child, I should commit it to an assistant with directions to force the air, slowly, gently and at intervals into the chest, whilst I alternately pressed its walls with my hand.

This plan I take leave to think is physiologically and chemically more likely to prove successful than that pursued by Dr. F.; I should be glad if it were more frequently and perseveringly tried, and the results of such trials recorded.

I may just mention that I am not anxious to propound any views of my own or to differ from Dr. Farre, except that I am persuaded it is only by cool, deliberate, and disinterested discussion that the true value of any mode of practice can be elicited, a sentiment, the expression of which by Dr. Guy in his first communication, encouraged me to put the queries contained in my letter to yourself, in No. 272 of the last vol. of your useful, independent, and well conducted periodical.

I am,
Your's respectfully,
A. W. CLOSE.

Manchester, Feb. 22nd, 1845.

HOSPITAL REPORTS.

SURREY DISPENSARY.

Low Continued Fever.—William F. æt 24, servant, residing at Broker's Row, Borough, was admitted under the care of Dr. Aldis, March 8th, 1845. Pulse very feeble, hands tremulous, tongue black and dry, the patient is unable to protrude it beyond the teeth; motions passed involuntarily as well as the urine; has been convulsed and has bled profusely from the nose and mouth, by which the pillow and sheets were several times saturated with blood, no sleep, lies on his back.

Ailing a fortnight. Illness commenced with shivering, headache, and delirium, when he was removed from "his place" in the city; afterwards leeches were applied to the head on Sunday and the hair shortened; a rash appeared on his body the same day.

℞. Hydrarg: c. cretâ
Pulv. Doveri ana. gr. iii. bis de die ad quatuor vices.
℞. Ol. Ricini ℥ss. cras et alt. mane.
℞. Æth: sulph: f ʒss.
Tinct. Serpentariæ f ʒj
Mist. camphoræ f ʒxi. 4tis horis.
℞. Vini rubri. f. ℥ ss. ex aquâ 6tis horis.
Beef tea and arrow root.

10th.—Pulse quick, easily compressible, always sleeping, tongue dry and warm, no trembling, jactitation frequent, slight delirium last night, bowels moved twice to day, no petechiæ.

Applicat. Emp: canthar: nuchæ.
Rep. Hydrarg. c. creta; omisso Pulv: Doveri.
Perstet in usu. misturæ.

11th—Pulse quick, tongue black, bowels open once to day, motions very offensive. Takes beef tea, arrow root, and chocolate, but no wine and water, gums slightly tender.

℞. Garg. aluminis.
Rep. oleum et mistura.

12th.—Pulse 90, no delirium, but appears much weaker; arms tremble, opens his mouth, but does not protrude his tongue, says he cannot, motions last night voluntary, urine much in quantity, very turbid, slips down in the bed, dorsal decubitus.

Rep. hydrarg. c creta gr. iii. c. ipecac. t. d.
℞. Ammon. sesquicarb. gr. iii.
Tinct. serpentariæ ʒj.
Infus. gentian. ℥j. ter die.
Emp. canth. pone aures.

13th.—Tongue cleaner, bowels open, motions more healthy, urine free, voluntary, pulse quick. Takes wine and water.

Rep. mistura et oleum; omisso pulvere.

15th.—Much improved, tongue clean and moist, protruded easily, is cheerful, and says he feels much better. Pulse 96, weak; bowels freely opened last night; mouth tender.

℞. Acid. nitric. dilut. M. xv.
Aquæ f. ℥iss. ter die.
Rep. ol. ric. ℥ss. alt. mane.
Rep. Vinum.

25th.—Appetite very good; left his bed yesterday and Sunday for a couple of hours. Perstet.

April 1st.—Came to the Dispensary. Tongue whitish, fissured; pulse quick and weak.

℞. Infus. cascarillæ, f. ℥xi.
Sp. æth. nitrici. M. xv.
Syrupi. ℥i. t. d.
Rep. ol. ricini.
5th.—Discharged cured.

Facial Paralysis. Lydia F., æt. 15, residing at 4, Essex-court, Park-street, admitted under the care of Dr. Aldis, March 18, 1845. On Friday morning observed the right side of her face to be drawn to one side; no fit, nor pain in the head, there is much discharge of watery fluid from the right eye, the inferior eyelid being everted; the right angle of the mouth is lower than the left, hesitation of speech, sensation the same on the right side of the face as on the left. Pulse quick; catamenia regular. Has not been exposed to cold.

Applic. hirud. vi. pone aures.
Postea cataplasma lini per horam ½.
Emp. canthar. nuchæ cras.
R. cal. c. jalap. gr. x. statim et alt. mane, ad duas vices.

20th.—Pulse 108 soft; skin cool; pupils contractile, no pain in the head now, but has experienced very severe pain behind the right eye; cannot move the muscles on the right side of the face; on endeavouring to laugh when told, she moves the muscles of the left side of the face only. Retains her water with difficulty.

Ung. Sabinæ parti exulcerat.
H. cath. alt. mane.

25th.—Pulse 96; tongue white; bowels not open since Sunday, paralysis gone, no hesitation of speech: blistered surface discharges freely. Omitt. ung. sabin. H. aperiens bis die.

April 1st, discharged cured.

PROGRESS OF GERMAN SCIENCE.

By Sigismond Sutro, M.D.

The Effect of Wax upon the Odorous Principle of Musk.—M. Kallhofert, in following up the investigation on this subject previously made by M. Pfeffer, found that the odorous principle of all the varieties of musk is absorbed by wax. He folded a quarter of a grain of purest Tonkin musk in a piece of waxed paper, and found that the drug became completely inodorous after being wrapped up for an hour and a quarter. In his second experiment, half a grain of genuine Oriental musk, triturated with twelve grains of sugar, was enclosed in an envelope similar to that used in his first investigation. After an hour and a quarter had elapsed, though not quite scentless, the musk had almost lost its perfume. The experimenter found, that exposure of the waxed paper to ammoniacal vapour, was successful in again restoring, though not completely, the vanished aroma of the musk. From this he infers, that paper coated with wax, or wax itself, possesses the singular power of absorbing the odorous principle of musk. Other substances, which he has discovered by later researches, also possess this power; among these, he reckons golden sulphuret of antimony, sweetened emulsions, quick lime, and precipitated sulphur. Heat, as well as ammonia, causes a re-evolution of odour from scentless musk. M. Kallhofert concludes, by stating it as his opinion, that the above substances deprive musk of its odour, chiefly on account of the affinity they entertain for the ammonia, which enters into the composition of the drug. He declares it his intention to prosecute still further the investigation of this curious subject.—*Kallhofert of Swanndorf, in Buchner's Repertorium.*

Preparation of Protoxide of Copper.—Though the property which sugar possesses of reducing persalts of copper to protosalts of that mineral, has long been known to the world of science, it is but a few years since, that it has been applied to practice by M. Bottger, the able chemist of Frankfort. He has succeeded in preparing a protoxide of copper, in the moist way, by the following process:—Nine parts of peroxide of copper are added to a heated solution of twenty parts of cane sugar in sixty parts of water, previously alkalised by potash water, containing eighteen parts of hydrate of potash to sixty parts of distilled water. These substances are kept for some time at a heat above 200°, and are then removed from the fire; as the liquid cools, the protoxide is deposited as a ruddy amorphous powder.

To this *modus operandi* objections have been however taken, on the ground of the expence of the chemical so prepared. To remove this obstacle to the common employment of the cupreous protoxide, the writer of the present paper, following up Trommer's idea that "sugar of milk reduces the persalts of copper with more facility than cane sugar," adopted the following plan:—One part of sulphate of copper, and an equal quantity of sugar of milk are added to ten parts of distilled water. Aqua kali purum, sp. gr. 1·333 is next added, until the precipitate thrown down by the first portion of that alkaline liquid is again dissolved. The solution, now of a bluish colour, is gradually heated with constant stirring, until it assumes the following shades of colour—greyish-green, greenish-brown, light-brown, and, finally, vermillion; when the vessel containing it must be immediately removed off the fire. The precipitate is separated by filtering, pressed, washed, and dried, when it presents the appearance of an amorphous powder, with the peculiar colour of the metal of which it is a salt. If the solution from which it is obtained be exposed to further heat after it has once assumed the vermillion colour, the peculiar ruddy appearance of the protoxide is lost, it changes into a dirty crimson colour, while its state of powdery shapelessness is exchanged for one definitively chrystalline. It is conjectured that in this state it is no longer a protoxide, but a combination of the former with peroxide of copper. When prepared agreeably to the first directions, the protoxide is perfectly anhydrous, rutulent as the metal copper, readily soluble in muriatic acid, and unsullied by the slightest trace of organic matter. A less expensive method than either of the above has been suggested for the preparation of this compound, but the resulting salt is always impure, being invariably adulterated with variable proportions of the peroxide; it consists simply in placing sheets of copper in a crucible in a furnace, and exposing them to a red heat until their surface becomes oxygenized. They are then withdrawn, the mixed oxide scraped off, and again replaced in the furnace; this process is adopted until the copper-plates are so thin as to be quite useless. This mixed oxide is of a greyish-crimson colour, and generally contains about one twentieth of its weight of protoxide.—*Dr. Wittstein Opere Citato.*

Experiments to Ascertain the Effects of Fuselol on the Lower Animals.*—In these investigations the fuselol employed was of the sp. gr. 0. 8, and completely free of alcohol. The first experiment was performed on the small intestines of a dead rabbit, the mucous membrane of which, under the action of the fuseol, became studded with numerous minute angular points, which gradually assumed a circular shape, and ultimately vanished. Live animals—rabbits and a dog—were the subjects of the succeeding experiments. The injection of two drachms of this substance into the respective stomachs of two rabbits, produced in each all the symptoms of intoxication, attended with coma, a state from which, they however recovered in about three or four hours. In these, as in all the animals afterwards experimented upon, the breath was strongly odorous of fuselol. Three drachms of this substance were injected into the stomachs of other rabbits, without producing any other effects than those detailed in the first experiment. Half an ounce and an ounce administered in like manner to two more of these animals produced death, with all the symptoms of apoplexy from drunkenness. In the latter instance, death took place in the unusually short space of four minutes. The last subject of experiment was a middle-sized dog, to which were administered four drachms of fuselol. The animal became perfectly drunk in about five minutes after the above substance had entered his stomach. In some few minutes after it became motionless—fell to the ground—exhibiting no sign of muscular power, save a few faint semi-rotatory movements of the hinder extremities. The poor beast howled, its respiration was laboured and quick, its pulse frequent, so as not to be counted, its pupils dilated, and its breath strongly redolent of the poisonous substance; this train of symptoms was followed up by coma, which terminated in the death of the animal, about six hours after the poison had been administered. The bodies of both animals, examined after perishing, presented, with but trivial difference, similar appearances; the mucous membrane of the stomach was not inflamed in either, but in both was smeared over with a quantity of viscid mucus, while the submucous membrane was evidently in a state of engorgement; the duodenum and small intestines, in both were empty and perfectly healthy. The lungs of the rabbit were congested, but the heart, liver, and kidneys, exhibited no trace of vascularity, while in the dog, the respiratory organs, heart, liver, kidneys, and brain, were perfectly healthy. As the result of his experiments, the writer of this paper thinks himself warranted in assuming, that the effect of a small dose of fuselol is drunkenness, with its subsequent loss of nervous influence. That this substance taken into the stomach, operates by sympathetic nervous action; a supposition proved true by the rapidity with which it produces its intoxicating effects; that is absorbed into the pulmonary, and, in all probability, into the systemic circulation. The former assertion is proved, by the odour which the breath acquires on expiration, the latter by the aroma which all the internal tissues of bodies poisoned by this substance exhale when exposed for *post-mortem* investigation. At present it is not easy to ascertain the additional degree of power which this substance—introduced into the circulation—would acquire in inducing intoxication. Doubtless, it would be very great.—*Dr. Furst in Pr. Verein. Zeitung.*

* A substance procured in the distillation of spirit from oats, &c., and upon which the peculiar flavour of the spirit depends.

PROGRESS OF FRENCH SCIENCE.

FROM OUR OWN CORRESPONDENT.

Paris, April 6th, 1845.

Luxation of the Maxilla inferior into the Fossa Temporalis by A. Robert, M.D., Surgeon to Beaujon Hospital.—A carter was admitted into the above hospital under Dr. Robert. He had fallen asleep on his cart, and was thrown to the ground. Before he could recover himself the wheel passed over the right side of his face. On being brought to the hospital, the left side of the face and temple was found much swollen, and the right cheek was bruised and scratched; there was also a small jagged wound about an inch above the angle of the jaw; the mouth was thrown open and could not be closed, the chin was considerably inclined to the left, and the condyle of the lower jaw could be felt as a bony tumour just above the arch of the left zygoma. It was impossible that simple luxation could produce the above appearances; some other additional cause was to be sought for. The body of the maxilla inferior, on further examination was found fractured near its ascending portion, the lower fragment forming a prominence in the buccal cavity. The mode in which the dislocation was produced can easily be explained: thus the left side of the head was on the ground, and the wheel in passing from behind forwards, first fractured the body of the maxilla inferior, and then forcibly pushing that bone to the right, the condyle slipped out of the glenoid cavity, and ascended outside the zygomatic arch into the fossa temporalis: the coronoid process being behind the zygomatic arch, this part was received in the concavity which existed between the two processes. Reduction was performed as follows:—The man was seated on the ground, the operator placing himself before him, introduced the right thumb wrapped up in linen into his mouth, whilst with the fingers he seized the angle of the jaw, endeavouring to draw the bone directly downwards; unable, however, to accomplish the reduction, owing to the internal edge of the condyle being hooked on the superior edge of the zygomatic arch, the thumb was therefore carried in so as to reach the inner surface of the branch of the bone—the fingers remaining in the position already mentioned. The branch of the maxilla formed a lever of the first magnitude. After some slight effort the condyle was unhooked from the zygomatic arch, and by gentle traction

downwards was made to glide into the glenoid cavity. In order to prevent a renewal of the luxation, a four-tailed bandage, and the usual apparatus for fractures of the lower jaw was applied, and to combat the inflammatory symptoms, powerful antiphlogistics were employed, and with such success, that the only consecutive accident was an abscess in the right cheek opposite the fracture. The apparatus was removed on the fortieth day; the fracture was found to be consolidated, the patient could open his mouth easily, and experienced only a slight stiffness in the dislocated joint; on the fifty-fourth day he left the hospital quite well. (*Arch. de Med.*)

Extensive Burn of the Scalp Complicated with a Fall of the Two Ossa Parietalia and the Os Frontis. — The following curious case, which came under my notice at a late professional *reunion* at Dr. Amussat's, is perhaps unique and worthy of being recorded not only on that account, but because it may serve as a warning to mothers, and prevent them confiding their children to mercenary hands. M——, 11½ months old, born of young and healthy parents, was, as is too frequently the case in France, confided to the care of a nurse who resided at some distance from the father and mother; the child, previous to the accident about to be related, constantly enjoyed good health. About four months ago, the nurse left her house, locking up her own three young children, and the other young child which she left in a low chair near the fire. On her return—she had been absent at least half an hour—she found the infant lying on the hearth insensible, its sinciput exposed to the action of the fire and its forehead resting on the fender. How the accident had happened, or how long the child had been in that position, it was impossible to say. Its black silk cap and the portion of the scalp covering the two parietalia, and the upper part of the frontalis were completely carbonized into a homogeneous black mass; the burn likewise extended downwards on the forehead, the temples, and cheeks. A medical man who was called in ordered an oleo-calcareous liniment to be applied to the scalp, the bowels to be kept open, and a few leeches to be put on behind the ears. The child remained perfectly insensible for four days, after which it gradually recovered and soon took the breast with as much avidity as before. An abundant suppuration, as might naturally be expected, followed so serious a lesion, and detached by degrees the two parietalia, and the ossified portion of the os frontis, laying bare the dura mater. The pulsations of the brain were distinctly perceived whenever the child cried. About a month ago, the child made a sudden movement while the mother was dressing the wound, and having involuntarily touched the left parietal bone she heard a sharp noise as if something had snapped, and immediately an abundant venous hæmorrhage took place. Shortly after, a small tumour appeared on the left side of the longitudinal sinus, just above the forehead. It gradually increased, and is now about the size of a walnut; it is soft and compressible, and whenever the child cries, pulsations similar to those of the brain are visible. The different practitioners present at the meeting coincided with Dr. Amussat that the tumour was a species of aneurismal sac formed by dilatation of the internal membrane of the longitudinal sinus and filled with venous blood. This diagnosis proved to be correct, for on making gentle pressure on the sides of the swelling, it burst, and through the opening a little coagulated blood escaped. The opinions with regard to the treatment were far from being unanimous, some preferring the ligature, others cauterization; the majority, however, agreed with Dr. Amussat in employing pressure alone by means of a plate sufficiently large to cover the whole of the denuded portion of brain. What is extraordinary in this case, is that there were no convulsions or any other serious cerebral or general symptoms, and that the intellectual faculties and physical powers are as highly developed as they usually are in healthy infants of the same age. About one half of the ulcerated surface has already healed. I shall watch this case carefully to its termination and let you know the result.

Professor Piorry will commence his summer course of lectures on pathology on the 8th instant. All the medical or surgical clinical facts relative to percussion will be passed in review, and the physical signs furnished by plessimetry will be compared, with the other diagnostical signs obtained, by various other means.

Academy of Sciences; Sitting of the 31st March. M. Elie de Beaumont in the chair.—The election of a corresponding member in the section of botany, vacant by the death of M. Bouché, of Abbeville, took place. M. Lestiboudois, of Lille, having obtained the majority was declared duly elected. The other candidates were MM. Moquin-Tandon, of Toulouse, Feé, and Schimper, both of Strasburgh.

On the Circulation in the Mollusca: Class Brachiopodæ. By R. Owen, Esq. F.R.S., &c., presented by Mr. Milne Edwards, M.A.S. Since the communication of his former memoir to the Zoological Society in 1833, (1) the author, in prosecuting further the anatomy of the *brachiopodæ*, met with a condition of the central organs of circulation in these mollusca, which he considered as a peculiarity, until the perusal of of Mr. Milne Edwards' observations (2) on the diffused venous system in other orders of that sub-kingdom, showed him that it formed part of the general rule, and that the *brachiopodæ* are an important link in the chain which connects the molluscous with the sanguiferous classes of animals. Each auricle in the *terebratula flavescens* is a capacious receptacle with muscular parietes, which the act of contraction throws into numerous fine radiated folds. Its form, in this contracted state, is that of an oblong depressed cone, which is perforated by the auriculo-ventricular orifice, and communicates directly and freely with the peritoneal and visceral cavity by the wide aperture at their base, or rather, with the wide and irregular venous sinuses which line that cavity, surround the intestinal canal, and insinuate themselves between the lobes of the liver, and the commencement of the glandulo-generative masses. From the lateral parts of the general visceral sinus, the large venous prolongations are continued under the form of vessels upon the mantle lobes—two trunks upon the upper, or dorsal lobes, and four upon the lower, or ventral, lobes—and along these trunks, or prolonged sinuses, the sperm-cells in the male, and the ova in the female, are developed, and are bathed in the blood contained in these prolongations from the great central sinuses or peritoneal receptacle, where the commencement of the generative organs is lodged. If the terebratula be dissected from the dorsal aspect, the imperforate valve, and corresponding mantle removed, and the membranous wall of the visceral cavity, or peritoneum, cut off, the auricles are seen above, behind the stomach, and extending to the sides of the commencement of the intestine; and the wide basal openings are immediately exposed. The delicate membrane attached to their margin and continued from it upon the adjoining parts of the visceral cavity, must be regarded as peritoneal, or as analogous to the internal tunic of a vein or sinus dilated co-extensively with the proper peritoneal membrane of the visceral cavity. In a lateral dissection of the terebratula, a portion of this membrane is left, partly covering the wide opening of one of the auricles. The plicated walls of the auricle seem capable of great dilatation; a small portion smoothed out, or flattened, presents, under the microscope, a delicate layer of external transverse fibres, and still finer internal longitudinal ones radiating from the apex. When the circulating fluid has accumulated in the great visceral sinus, it may be presumed that it is drawn into the auricles by an action analogous to that of suction, and then propelled by the successive contractions of the transverse sphincteric fibres of the simple ventricles. From these cavities, the blood is driven chiefly to the pallial arteries, and returns by the commencement of the wide venous system, which constitutes the pallial veins, or ovarian sinuses, from which it passes into the still wider and more diffused visceral sinuses. In the *lingula anatina* after removing the glandular masses which surround the intestine, and which most probably receive from it the nutritious fluid analogous to chyle, the blood mingles directly, and without the intervention of a chyliferous system, with the blood contained in the sinuses which are continued from the intestinal sinus into all the interspaces of the abdominal viscera, and the blood in which is finally received by the widely opened abdominal orifices of the plicated contractile auricles, whence, as in the terebratula, it is propelled into the ventricle, and exhausts its impulsive force chiefly upon the pallial and branchial circulation. After several learned remarks on the alimentary canal, and the nervous system of the brachiopodæ, this interesting communication terminates thus. "The Brachiopodous family of mollusca being the most widely diffused over the earth's surface and extending to greater depths than ordinary bivalves, are interesting on account of their extensive range through space; nor are they less remarkable for their duration in time, being amongst the oldest existing forms on this planet. 'Every particular theory, therefore, respecting a plan of organization which can accommodate itself to the varying conditions of one of the most diversified provinces in the geographical distribution of animal life, and which has so long been able to resist the great destroyer of things, *tempus edax rerum*, will be acceptable to the philosophical naturalist, and the additional observations here presented will be particularly interesting as they add another instance of the prevalence of that diffused condition of the venous system which the important discoveries of Mr. Milne Edwards has shewn to be a general characteristic of the whole of the molluscous sub-kingdom."

On the Digestion and Assimilation of Sugar and Amyloid Substances. A memoir read by M. Mialhe.—The author, after shewing that his ideas, researches, and theories on the action of alcalis on sugar or amyloid substances considered with respect to their assimilation, are anterior to those of MM. Bouchardat and Sandras, presented on the 20th January, 1845, and different from those of M. Chevreul, details in the second part of his memoir the results of further researches which confirm his former ones, and "that the essential parts of the alimentation in animals is formed of three distinct substances: albuminous; fatty; and saccharine—that these substances must remain in the gastric or intestinal cavities, and undergo a sort of fluidification or fermentation, a physico-chemical action to which the term *digestion* has been given—that notwithstanding the researches of Reaumur, Spallanzani, Leuret and Lassaigne, Tiedemann and Gmelin, Eberle, Schwann, Deschamps, &c., the mode in which the gastric function acts on this substance is far from being well known." It is admitted: 1° That albuminous substances are assimilated by the aid of the gastric juice, which by its acidity causes the azotised substances to swell and by means of its *pepsine* to be liquified; 2° That fatty substances are assimilated by means of the bile. But for feculent and saccharine substances nothing positive has been advanced, and it is this hiatus which the author seeks to fill up, and he considers that it can be explained by the discovery of the active principle of the saliva. This principle is solid; white, or greyish white; amorphous; insoluble in pure alcohol; soluble in water and diluted alcohol; its aqueous solution is nearly or entirely insipid, neutral, not precipitated by the sub-acetas plumbi, spontaneous decomposition changes it into butyric acid, or a substance very similar to that acid; it exerts no action on azotised principles (fibrine, albumine, caseine, gelatine or gluten) or on the ternary neutral substances (cane-sugar, inuline, gum arabic, and lignine); has a powerful action on starch, producing with anhydrous fecula, dextrine and glucose. Added to fecula mixed with seven or eight times its bulk of cold water, this substance, by a digestion of several days, completely dissolves the starch. This effect may be more readily obtained by keeping the mixture at a steady heat of 170° F. The starch thus dissolved is no longer coloured blue by the addition of iodine; potash heated with it produces a darkish brown colour, indicating that the fecula

has been changed into dextrine or glucose. The quantity of these two substances may be ascertained by filtering the liquid and treating it with six or eight times its weight of absolute alcohol, the glucose is dissolved and the dextrine precipitated. Its action is so powerful that one part is sufficient to convert 2,000 parts of fecula into dextrine or sugar. As to the analogy between this principle and *diastase*, the numerous experiments detailed in the memoir tend to prove that they are identical in their chemical properties, consequently the author proposes to call it *animal or salivary diastase*, as a contrast to the active principle of the cereals which he proposes calling *vegetable or amylaceous diastase*. *Mode of preparation*: filter the saliva, treat the filtered liquid with five or six times its weight of absolute alcohol, as long as a precipitate takes place; the diastase is deposited in flakes; after being separated from the alcohol it must be dried on a glass plate in air heated to 122° F., and kept in a well-corked bottle. From the facts contained in this memoir, it may be concluded that Professor Dumas has indicated the true character of the chemical phenomena of digestion, in placing them in the class of fermentations, since the dissolution of *azotised substances*, takes place by means of a ferment, *pepsine, that of fatty substances*, probably by means of a ferment contained in the bile, and that of feculent substances by means of the active principle of the saliva. In a future memoir, the author purposes giving the result of his experiments on the saliva of a great number of animals of different species.

On the Action of the Papaver Somniferum on Animals. By G. V. Lafargue, M.D., of St. Emilion.—The author fed several rabbits with this plant, and remarked that instead of its producing any bad effects, that on the contrary it proved to be a wholesome aliment, since they increased in weight. The plants eaten were very active, for a child was killed to whom a decoction of a single capsule was administered as an enema. The number of plants consumed every day was five or six; occasionally the powdered capsules mixed with bran were given the rabbits as food; and finally, grs. iv. of the acetate of morphine dissolved in ℥iv. of distilled water mixed with lb. ij. of bran were given without injury.

On Hydrophobia. By Dr. Fourcault.—The author recommends, when cauterization is not possible, circular compression above the wound, washing it with a strong aqueous solution of chloruret of lime or ammonia, with cupping; at the same time the person ought to be made to sweat profusely, by means of hot air and abundant drinks.

On the Volatilization of Zinc in Copper Foundries. By A. Becquerel, M.D.—The following fact proves that this substance exercises its influence not only on the workmen employed in the foundry, but likewise on persons who live in the neighbourhood. M. and Md. X—— and two workmen occupy a shop next door to a copper-foundry in which zinc is employed. The melting is performed twice a week, and on those days the four persons are always ill. Md. X——, who is the most seriously affected, complains on the evening of those days of violent shivering, accompanied by intense headache, lasting for about an hour. This is followed by considerable fever, lassitude, prostration, and pains in the limbs, which terminate by an abundant perspiration, leaving the patient very much exhausted on the intervening days. Md. X—— is pale, or of a yellowish hue, feels fatigued by the least exertion, walks with considerable difficulty; no organic lesion exists to which these disturbances can be attributed. The author considers them to be produced not by the metal itself; but by the oxide formed during its volatilization.

Academy of Medicine. Sitting of the 1st April. M. Caventou in the chair.

On the Microscopical Examination of Accidental Tissues By Dr. Rochoux.—The writer says—"I cannot refrain from condemning the faulty methods adopted by certain microscopists in studying accidental tissues. Thus, they examine with the microscope bits of degenerated tissues taken from cancerous tumours of the size of the fist, or tubercles of the size of the tip of the finger. But before these parts became so voluminous, these two kinds of morbid productions were the seat of various kinds of decomposition of putrid fermentations, which render it impossible to say what was the nature of the original tissue. For instance, when a tubercle is examined at such an advanced stage, the observer sees, in the midst of the drop of water in which it is placed, globules of pus more or less changed, blackish globules, presenting inequalities like the mulberry, which are supposed to be the final appearances of the tubercle or cancer. Such tissues are a detritus, in the midst of which any one can, like Adesson and Lebert, see all that they desire, and which teaches us the real character of accidental tumours with as much certainty as the examination of the refuse of vegetables can teach us botany. If the primitive tubercle is examined with the microscope, it is found to be of a globular, circumscribed shape, about 0·15 to 0·20 of a millimetre in diameter, buried, as it were, in the midst of the healthy pulmonary tissue which surrounds it. At this period, it may be extracted without breaking the numerous filaments which, composed of the remains of the pulmonary tissue, its vessels and nerves, form around it a sort of downy nest. Its colour, which at a later stage is of a dull greyish white, is now similar to that of gelatine, with a rosy tint which grows darker as the tubercle is smaller. After cutting it in two, if its surface be examined with a glass whose magnifying power is equal to 50 or 60, the morbid tissue seems to be homogeneous, like a jelly, or a solution of gum about to harden; but beneath a glass whose power is equal to 500 or 600, it presents a very different aspect. It is then found to be formed of filaments,—minute as those of the cellular tissue—interlacing each other, and containing no liquid in their cellular intervals; their texture is regular, and resembles, to a certain degree, that of the crystalline lens; the surface is of very pale-orange colour, and presents a metallic lustre. These peculiarities, which do not exist in strumous tumours, are only to be seen in tubercle in its nascent state. At a later period, and when it has reached the size of a millet seed, an effect produced by the reunion of several smaller tubercles, rather than by the growth of a single one, the pulmonary tissue contained in the interspace is changed, crushed, and pus subsequently is formed, in which those numerous and various products, so little noticed by the generality of microscopists, are to be met with. To avoid this error, into which others have fallen, we must impose upon ourselves the indispensable obligation of studying, at their earliest life, those accidental productions which degenerate like tubercle and cancer. As to those which, like fibrous tumours of the uterus, undergo little or no change, they without any inconvenience may be studied at any, or a very advanced stage; this, however, is but an exception, and does not prevent our admitting that almost all that microscopical anatomy has done towards investigating accidental productions, requires to be repeated.

On the Localization of the Faculty of Speech in the anterior Lobes of the Brain. By Dr. Belhomme (one of the candidates for the vacant place in the section of anatomy, and physiology). The conclusions of the author are 1°. That lesions of the faculty of speech depend either on a cerebral affection, or on some derangement of the organs of communication between the brain, and those which serve the purpose of articulation. 2°. That sudden loss of speech depends on hæmorrhage, or some other lesion of one, and especially of the two anterior cerebral lobes. 3°. That care must be taken not to confound the convulsive and paralytic phenomena which pervert the faculty of speech with sudden loss of remembrance of words, and subsequent difficulty of utterance. 4°. That in the disturbance of the anterior lobes of the cerebrum, the act of speaking is suddenly rendered impossible, and it is only when a cicatrix is formed in the brain, that the organ regains more or less its normal functions.

Dr. Reybard, of Lyons, began to read a memoir on intestinal suture, in which he criticised the report presented by Dr. Jobert de Lamballe. He was interrupted by the President, and many of the members, and was finally obliged to retire.

On the Solidity of the Bones and the Mode in which they resist the Influence of Foreign Causes; by Dr. Chassaignac.—The conclusions of the author may thus be resumed; 1° that the different modes by which foreign causes overcome the cohesion of the osseous tissues are, *tearing off or elongation, incurvation, crushing, twisting*; 2° that whenever any exterior force bends a bone, the convex fibres are elongated, and the concave shortened, but between the two, there are intermediate ones, which retain their normal length, so long as the curve is not carried beyond certain limits; 3° that the long bones being all of a prismatic form, possess the general conditions of the solidity of the triangular prism; 4° that a triangular prism offers greater resistance when any force acts on its angles than on its surface; the proportions being as 1 to 1·712; 5° that the tibia resists more when one endeavours to break it by acting on one of its faces than on its edges; 6° that the edge of the prism possessing the greatest power of resistance is that on which exterior causes act the most frequently; 7° that the bones are so arranged that almost all the exterior causes which tend to break them act on the part which presents the greatest resistance; 8° that from the shape of the bones, it is almost impossible that there should be parallelism between the *rupturing* cause and the osseous fibres; 9° that the apophyses of the extremities of the long bones are almost always continuous with one of the edges of the triangular osseous prism, and form as it were the base of a long pyramid, added to the central portions of the bone, and firmly fixed to it; a circumstance which gives it great solidity; 10° that in fractures which act parallel to the length of the limbs, the principle of their action is applicable not only to the contiguity, but also to the continuity of bones; 11° that the characteristic properties of the anatomical neck of the bones, with respect to their power in overcoming causes of fracture have never been indicated in a general manner. These are five in number, viz. (*a*) to offer a smaller diameter than any other part of the bone, (*b*) to be placed immediately under an articulation, (*c*) to occupy constantly that extremity of the bone situated near the trunk, (*d*) to form an angle more or less oblique with the body of the bone, (*e*) to present no muscular insertion between it and the articulation; 12° that the diminution of solidity in the central portion of the long bones, is compensated by the greater compactness of the osseous tissue in these parts; 13° that the long bones, twisted at the same time in the direction of their axis and their diameters, assume a spiral form, which constitutes the means of resistance against vertical pressure; 14° that there is a period at which the bones attain their maximum of solidity, after which gradually it decreases; 15° *fragilitas ossium* in old age does *not* depend, as stated, on the presence of an adipose substance in the tissue of the bones; 16° that three causes produce *fragilitas ossium* in old age: (*a*) the interstitial absorption of the osseous tissue, (*b*) the relative predominance of phosphate of lime during a certain time, (*c*) and at a later period, the partial absorption of the phosphate of lime itself, a cause which has never been remarked before.

Dr. Jobert de Lamballe gave the details of a case of fistula of the urethra, cured by the autoplastic method; the patient was present and was examined by several members of the Academy. This case will be given at length in my next.

GARLAND DE BEAUMONT, D.M.P.L., & S., &c.
Honorary Physician to the Spanish Embassy.

ON THE NATURE AND TREATMENT OF SYPHILITIC DISEASES.—At a meeting of the Surgical Society of Ireland, held on the 15th of March, a paper was read by Mr. Egan, surgeon to the Westmoreland Lock Hospital on the Nature and Treatment of Syphilitic Diseases, in which the views taken by Mr. Carmichael many years ago in his great work on Syphilis were fully established; though, as Mr. Egan candidly confessed, he had been at the outset of his investigation prejudiced against Surgeon Carmichael's doctrine. At the conclusion of the business of the evening, Mr. Carmichael rose to acknowledge the compliment paid him by Mr. Egan, which, coming from

such a source, was truly valuable. As they had nothing to do, perhaps they would listen to him for a few minutes while he gave them an account of the interested defamation of his work, which had appeared from the pen of a London reviewer, on its first publication. The reviewer was a young house-surgeon at the London Lock hospital—which was at that time attended by Mr. Pearson—to whose doctrines on syphilis, those promulgated by Surgeon Carmichael were completely opposite. He then entered into a detailed account of the unfairness and illiberality with which his work was treated by men of the highest character in the professional world, but over which it ultimately triumphed; and now stands an enduring evidence of his scientific skill and discrimination. He sat down after giving a brief resumé of the principal indications which should guide medical men in administering mercury for the cure of syphilis in all its various forms and stages. Familiar, as the profession must be, with Surgeon Carmichael's plan of treatment in syphilis, we take the liberty of presenting to them again an epitome of his invaluable opinions on the subject:—

1st. He does not think mercury necessary in the treatment of the simple primary ulcer without induration, nor for the papular eruption, and other constitutional symptoms it produces; but should the eruption linger into the fourth or fifth week after it has desquamated into scaly spots or blotches, mercury in alterative doses, either in the form of Plummer's pill or the proto-ioduret of mercury, will be of service in clearing the skin of the eruption, and in removing the pains of the joints, which are constantly present in this form of venereal. It should never be employed at the period when the eruption first appears in its papular form, at a time that it is usually preceded and accompanied by considerable fever, like all the other exanthemata, to which class of Cullen it obviously belongs. If mercury is exhibited prematurely during the eruptive stage of this as well as the other forms of disease, the scaly excepted, the skin may be cleared of the eruption, but in all probability it will return again and again to the great disappointment of the patient and perplexity of the medical attendant. 2nd. Mercury should be given in iritis so as to excite its full effect upon the system; the usual antiphlogistic measures to remove this dangerous inflammation are not to be neglected. 3rd. Mercury is to be given for the removal of nodes, for which purpose the iodide of that mineral is superior to any other preparation. 4th. In phagedenic primary ulcers mercury is always most injurious. They are most successfully treated by the application of strong nitric acid, immediately followed by a douche of cold water. The same application is also the most efficient for phagedenic ulceration of the throat, which if not checked will soon extend over the velum, uvula, and back of the pharynx, from whence it will spread upwards into the nares, and downwards into the larynx. Instead of the douche of cold water, in this situation inadmissible, a probang must be used, the sponge of which, moistened in a solution of soda or potash will neutralize any superabundant acid applied to the ulcers. During the eruption of pustules or tubercles which cause those crusts termed rupia, mercury is decidedly injurious, although its exhibition may at first flatter both patient and surgeon that the disease is yielding to this remedy. But the natural tendency of this eruption is also to become scaly after it has existed several weeks or months. This scaliness is a sign that the disease is on the decline, and indicates that mercury in alterative doses may then be employed with safety and advantage. Should any of the constitutional ulcers on the skin spread after the rupia crusts fall off, their progress may also be effectually checked by the application of nitric acid to their phagedenic margins. They of themselves first show signs of healthy reparation in their centres, which need not therefore be meddled with. Mercury in this stage of the disease, should not be exhibited. Hydriodate of potash, sarsaparilla, country air, and the tranquillizing effects of opium, should the patient be harrassed by extensive ulceration, are the constitutional means most to be relied upon. 5th. For the true Hunterian chancre with hardened edge and base, and for the scaly eruption which attends it, as well as the deep excavated ulcer of the tonsil, nodes and other symptoms belonging to this form of disease, mercury may be esteemed a certain and expeditious remedy.

NOTICES TO CORRESPONDENTS.

V. Q.'s *poetry is very curious, but not fit for our pages.*

Mr. Fitzgerald.—*The publisher knows of no applicant to suit.*

An Apprentice.—*No reference is made in the proposed Bill to the selection of Apprentices or Students. They will have to acquiesce in the law exactly as it may stand at the period of their examination.*

S. D.—*About 60 guineas.*

A Subscriber, M. B. *may register it is now said either as a Surgeon or Licentiate of Surgery and Medicine. The Bill will allow him to register as physician, if now legally practising as a physician; and the Council of Health will sit in judgment on the question of what constitutes "Legality." Our correspondent will see that we have no data to give him a specific answer. The Bill is on these, as on many other points extremely defective. The Registration List will be kept in London. There will be annual fees we apprehend.*

Mr. Obre's *address to the National Association has been received. We regret to say that numerous claims on our space must prevent our giving it insertion.*

Honestas.—*Should the integrity and honour of a certain Editor be doubted, Mr. Lawrence's evidence will at once settle the question.*

Civis.—*The public are much indebted to Sir J. Graham for preventing M. P—rical interference with the duties which properly belong to, and have always been exercised by Magistrates.*

A.—*An Irish apothecary, we consider, would be an eligible candidate for the vacancy in the Bethlem Hospital. The other fact suggested shall not be overlooked.*

T. C. B. *should apply to the College for a certificate of the grant of a diploma. The registration by the Council of Health could not, we imagine, be effected without documentary proof of qualification.*

Medical Enquirer.—*By the new Bill, we think no person in our correspondent's situation could practice as surgeon or accoucheur, if he (himself) assumed the ordinary appellation of a qualified medical man. On the other query, our correspondent should address himself to Mr. Belfour, the Secretary of the College.*

Mr. Wilson.—*We have no space for the responses the queries would bring us. The chemical theory in no way affects the orthodox treatment of phthisis now followed.*

Dr. Lewins has addressed to us a brief but satisfactory response to Dr. Clay's note. He protests against the tone and temper of that learned physician's reply, and remarks that the charge of recommending his son to surgical practice is best answered by the fact that that son is in H. M. S. in a remote part of the world on the frontiers of Southern Africa. Here we part finally with this unpleasing episode in our scientific correspondence. We are happy to add that our next number will contain an article from Dr. Lewins on uterine and ovarian disease, promised to us some time since, and which, though written before Dr. Clay's letter appeared, the learned author thinks its best practical commentary.

Mr. Warrene's *paper on mesmerism shall be published, if we can contrive to make room.*

We have to acknowledge with our best thanks, the following subscriptions to "The Medical Times Defence Fund."

	£.	s.	d.
Dr Costello	5	5	0
Mr. Turner	2	0	0
Mr. Wood	1	1	0
L. R. F. (a Friend)	2	0	0

N. B.—*We shall feel obliged if gentlemen will kindly withhold any subscriptions they may propose sending in this matter till the result of the trial be known.*

Several notices and replies are precluded admission till our next, including several reports of meetings.

THE MEDICAL TIMES.

Saturday, April 19th, 1845.

Grande et conspicuum nostro quoque tempore monstrum.

A distinguished surgeon, writing in one of the morning journals, declares that the "*tracasseries* of the medico-political mountebank" (Mr. Wakley) "are beneath the dignity of discussion." True—*very* true—and yet (sad to say!) they *must* be "discussed." The "*mountebank*" will not allow one to take refuge in "*dignity*." His impudent jugglery breasts us till, in mere self-defence, we pocket our "dignity," and coolly knock him down. We must "discuss," and examine, and condemn, or the "*tracasseries*" will pass with those who cannot think, and those who have not time to think, for exercitations of public virtue. Every instinct within us may shrink from the repulsive duty, just as the well-dressed passenger avoids the affray of the insolent sweep obstructing his pathway; but there is no help for it. "Dignity" is made a luxury far too costly and perilous to be safely indulged in. We must tread on the viper, or recoil, leaving in full play its slime and venom;—we must do a justice that revolts one's sympathies, or give restless wrong a disgraceful triumph. *Marat*, the "medico-political mountebank" of the French Revolution, would have lived harmless to hundreds of heads, if Lafayette (respectable man) had not thought—and in practice, too,—the journalist "*tracasseries*" of that incendiary' beneath the dignity of discussion." The best use to which you can put your really noxious animal, is to scotch him, and the worst use to which you can put your "dignity" is to let it prevent you. The office of moral executioner may give one's gentility a sad pang, but it saves a great deal of after trouble and useless repentance.

The last "*tracasserie*" of our humoursome "mountebank" is a violent attempt to assassinate that object of so prolonged and ardent a courtship, the National Association of General Practitioners. The Committee-men, it would appear, by a monstrous metamorphosis more wonderful than any known to Ovid, have become transformed, all of a sudden, from forms the most angelic, to shapings the most brutal and diabolical. It is really shocking to sensitive nerves to hear into what atrocities these once lovely creatures have suddenly leapt. We who for months had seen "the mountebank" weekly exhibiting them "from his *camera obscura*, as, so fair, so perfect," that even old friends should, at any expense of honor, be sacrificed for them, stand horror-stricken at the picture of deformity he now gives us, as their *vera imago*. Poor, honest, simple soul! how sad that he should have been so deceived in them! How grievous to see the contortions of his Charlatan countenance, while compelled to describe *that* to-day to his admiring audience as hideously black, which yesterday he protested was lily white! How visible his tears—how audible his groans—how credible his tortures! But they are not for himself—virtuous soul!—they are for the infatuated Committee-men, who will not—*really* will not—be exactly what he wishes them! Tasteless wretches! they will not return his love! Tears and sighs, prayers and threats, love and hate, admiration, vituperation—are all in vain! Like Shakespeare's Helena,

"The more his prayer, the lesser was his grace!"

Alas! why will not the Association be ravished by a love which shews the sincerity of its excess by the madness of its victim! Hard-hearted, unkind Association!

There was a time when the "*mountebank*"—half conceiting himself a medical O'Connell—(and really as much and pleasingly like him as the ape to man)—exclaimed "Hurrah for President Pennington!" There was a time when "the demand for an Incorporation of General Practitioners by Act of Parliament," under "the *venerable* Mr. Pennington," was declared the most "righteous claim ever raised by a *high*-minded body of scientific men!" There was a time when the Committee was praised because putting forth their "Suggestions" without calling a public meeting, they wisely severed the responsibility of them from the body in whose name they acted. There was a time when the ruling body of the Association was described as a "Committee consisting of gentlemen of the highest position and character in the Profession, and whose rank, emoluments in practice, and independence, SHIELD THEIR PURE AND HONORABLE MOTIVES FROM EVERY TAINT AND IMPUTATION OF SUSPICION!" But those halcyon hours of hopeful love are past;—the coldness—the scorn—the contempt that met each advance have produced, at length—after months of heroically borne indignities—their effect, and when the last desperate effort at possession—the generous offer of ten guineas!—turned out as fruitless, as the verbal wheedlings and ingenious intrigues that preceded it, the gentle passion gave way forthwith to rage—the *spreta formæ Junonis* came into full play—all the woman took possession of his soul, and we have had ever since an insensate vengeance harmless to all but himself! Poor, poor *thing!*

Such "tracasseries" are *indeed* beneath the dignity of discussion. It is sad to think that they can even be essayed, in brazen-faced confidence, to gentlemen, our fellow members of a learned calling. For, what mind but must revolt to see personal spleen, with motives of the lowest and most sordid character, impudently protruding themselves as public virtue, and demanding from a learned Profession support and countenance at the very moment that a miserable and unprincipled egotism is placing in jeopardy our dearest interests? What now is charged against the National Association, which months ago could not quite as justly be brought against them? What if the members, in greater part, live west of Temple Bar? Does east or west of that mystic barrier change the interests of the medical denizens in the welfare of the Profession? Is right or wrong in medical politics so geographical a quality, that it is one thing to western, and another to the eastern residents of the metropolis? Above all—supposing it evil—how did the expulsion of Wakley from the Committee—he a *western*—first fling light on this *crime* of occidental preponderance? The omission of *adding* to the fault should, at least, not have been used as the first occasion for its punishment. The truth is, that beyond the mere differences of opinion on principle and action, which must ever exist where large masses of human beings are concerned, no single ground of cavil can now be advanced against the National Association with any show of reason or propriety. Nobody has ever dared publicly to doubt that the Committee, as a body, is composed of very high-minded and independent men, and we will do them the justice of saying, that never before, did gentlemen, with actual injury to their *own* immediate pecuniary interests, devote themselves with more industry and good feeling to promote the general welfare of their order. Individually, we know that no medical Bill that may be passed can affect a single iota, the practice of the majority—including *every* member of the sub-committee—and from the quiet, unpublic character of their past lives, it may safely be predicated that nothing but generous feeling for the endangered well-being of their younger brethren, could have induced them to take an active share in the present agitation. We trust therefore, that, as long as they pursue that independent and fearless course of action which has marked their past proceedings, and which so well befits their character and social standing individually, that no aid, in the power of our brethren to render them will be withheld. This is the greatest occasion for setting our profession on its true footing that Parliamentary history has known; and if marshalling all our forces, we support, in serried ranks, the first great central body that has so happily been organised for the Profession's Protection and Government, we cannot fail to have crowned with success every one of our reasonable expectations. The interview with Sir James Graham, given in another page, is an encouraging augury of the splendid results within our grasp if we *be wise, and divide not!* The price demanded is surely not too dear for so promising a purchase!

"Verum contra, qui graciles, et temperamenti biliosi, aut melancholici, sanguinem acrem, aut retorridum, cerebrum calidius, atque spiritus animales nimis incitatos, et irrequietos habent, a potu isto Thea, prorsus abstinere debent."—Willis.

—"Licuit, semperque licebit,
Parcere personis, dicere de vitiis."—Horace.

It has been proved by physiological experiments that tea possesses, in a very marked degree, the power of affecting the nervous centres. It is upon the cerebro-spinal axis that its effects are chiefly manifested. Green tea, especially, is distinguished by this property. It is said that a strong solution of it, applied to the sciatic nerve for half an hour, has caused death. Introduced in only small quantity beneath the abdominal integuments of a frog, it produced complete paralysis of the hind legs lasting for some hours; and even on the following day, motion and sensation were not fully restored to the affected organs. Administered as an injection to a dog, it caused a perfect paralysis of the vesical and intestinal sphincters; a partial loss of power in the hind legs, and a total loss in the tail: this organ was for some time immoveable, and as it slowly recovered its sensibility and vigour, exhibited a variety of grotesque movements. A strong infusion of tea introduced beneath the integuments covering the left side of the chest of a dog, has occasioned a feeble and an intermittent action of the heart. A poultice of green-tea leaves applied over the human stomach has caused sickness and vomiting—over the abdomen, colicky pains and purging—over the heart, faintness and irregularity of pulsation—over the kidneys, diuresis. A strong extract applied to the inner surface of the eyelids produces dilatation of the pupil and indistinct vision: introduced within the ear, it occasions deafness and *tinnitus aurium*. It is believed to hasten the process of labour already commenced, and has even been affirmed to have produced abortion. An old couplet, says—

"Savine, rue, and tea beware,
Wives who'd have a mother's care."

A strong solution of tea, injected into the jugular vein of a dog, accelerates the heart's action for a short time and then depresses it in a much greater ratio; occasions convulsions, vomiting, purging, dilatation of the pupil, and paralysis—either slowly recovered from, or less slowly terminating in death, as the quantity and strength of the material may be. A similar solution introduced into the carotid artery, produces excessive convulsions and spasms, especially of the extremities, widely dilated pupil, stertorous breathing, irregular action of the heart, spasmodic respiration, hiccup, and final coma. These facts prepare us to receive the statements of certain authors concerning the injurious influence of tea upon the human constitution, and will prove confirmatory of certain further observations we ourselves have to make upon the same subject. Trotter says:—"There may be conditions of health, indeed, where tea can do no harm—such as in the strong and athletic; but it is particularly hurtful to the female constitution; to all persons who possess the hereditary predisposition to dyspepsia, and all diseases with which it is associated—to gout, and to those who are naturally weak-nerved.

Ye hipped, weak-nerved, and melancholy,
Tobacco or tea will speed your folly.

Fine tea, where the narcotic quality seems to be concentrated, excites nausea and vomiting, tremors, cold sweats, vertigo, dimness of sight, and confusion of thought. I have known a number of men and women subject to nervous complaints, who could not use tea in any form without feeling a sudden increase of all their unpleasant symptoms; particularly acidity of the stomach, vertigo, and dimness of the eyes." The observance of similar morbid effects from its use, induced Hermomane to call tea a "seminary of diseases." Millingen says of this herb, "in some it is highly stimulant and exhilarating; in others its effects are oppression and lowness of spirits; and I have known a person who could never indulge in this beverage, without experiencing a disposition to commit suicide, and nothing could arouse him from this state of morbid excitement but the pleasure of destroying something, books, papers, or any thing within his reach. Under no other circumstances than this influence of tea, were these fearful aberrations observed." Such, and so many, are the peculiar effects which tea is capable of producing upon the animal and the human species. It is pretty evident from them, that the action of tea is in some sort, intermediate between that of digitalis and opium. It approaches the former in its influence upon the heart, and the latter in its influence upon the brain. It may seem paradoxical that the same substance should combine the properties of stimulant and sedative, but though we cannot explain the anomaly, we are quite familiar with the fact. At the very time the heart is being enfeebled in its pulsations, at that very time also is the brain roused to extra vigour. Can it be that a depression of the mere animal or organic function leaves the intellectual more at liberty and unfettered? The idea is not without its probability, for it has some analogies in its favor. Prior to dissolution, when bodily strength fails, the eye will become brighter, the senses more acute, and the intellect more brilliant, than ever. So also the prostration of physical energy which immediately precedes fainting, is often the opportunity for the mind to exercise momentarily, but marvellously, its privileges. In that instant of time, imagination has sometimes performed gigantic feats—ideas, plans, and enterprises, have been conceived, not in outline, but in detail, which it would occupy an age to re-produce. We knew a student, of poetic temperament, upon whom strong tea produced so sedative an effect, that an extra quantity of it invariably caused him to faint. For the production, however, of those lively imaginings in which he was formed to indulge, he was in the habit of sipping tea until it rendered him, as he said etherial. He would sit in complete reverie for

hours, indifferently conscious of whatever might be passing around him, feeling no animal sensations, but possessed with the idea of imponderosity, and floating, as it were, in a gorgeous and boundless region of thought. The descriptions which he gave of these journeyings through ether, were of the sublimest kind—nothing material mixed itself with them—they were grand in the magnificence of pure mind, which seemed never to have been incarcerated, had received no earthly tutorage, but shed its lovely idealisms like sunshine, the issue, spontaneous and original, of its single essence. Nothing that I have ever heard or read has impressed my mind with a belief in the possibility of innate ideas so much as that student's account of his wakeful visions. We have known similar effects to be produced, though in a much inferior degree, upon others, whom tea affected chiefly by debilitating the nervous system, and we have known like consequences to follow the sedative action of tobacco and digitalis. We are therefore of opinion that the temporary increase of intellectuality which some people enjoy from a strong infusion of tea, is due not alone to a direct action upon the brain, (speaking of it as the organ of the mind) but partly to that action upon the animal system which lessens its vigour, and consequently its controul over the mental operations. There is a certain but an undefined relationship between physical and intellectual existences, as these constitute the mind and body of living man; there is a degree of controul which they are capable of mutually exercising over each other; and they are reciprocally each other's dependent. But though there is a balance between these entities which can only be broken by death, yet according as the one or the other may be educated, will it be powerful and predominant. There is a boundary which cannot be passed by either; but within that boundary reside many privileges, physical or mental, as constitution or habit may determine. What intellectual education does, progressively and permanently, upon all subjects susceptible of its influence, tea, and other like matters, are capable of doing *temporarily*, upon certain subjects. Education elevates the mind above the enthralling dominion of the physical powers—tea subdues these for a time, and gives the mind a freer opportunity of spontaneous exercise.—Hence it is that its intellectualising tendency is some test, either of the amount of cultivation or of the aptitude for it, in the individual upon whom it operates. Tea will not make a naturally stupid man intelligent, nor an ill-read man learned—but it will aid both memory and imagination, if the one be already well stored, and the other only fundamentally well cultivated. So much for one of the modes in which tea operates. Before proceeding to examine the other, it will be well to mention some of the evil consequences to which the sedative action of tea gives rise. First let us mention diuresis. Tea is not a diuretic, properly so-called—that is, it does not *directly* stimulate the kidneys to increased action as dandelion, broom, juniper, and other like vegetable substances do, but it acts through the agency of its depressing effect upon the system at large, whereby, as old Macrobius says, " the reins become as sieves through which the body wastes its gentle humours." In this respect tea acts like fear, melancholy, and those depressing passions which arise either from a disordered mind, or from a body depraved by indulgence and dissipation. The consequences of this diuretic action are very often either particularly unpleasant or painful. We once remember a popular Dissenting preacher who had attracted a large and fashionable assembly to hear his discourse, being compelled to vacate the pulpit for a few minutes in consequence of having drunk a large quantity of tea before commencing his service. This is a practice that Dissenting preachers are much addicted to; and whilst it seldom fails to visit them with immediate uncomfortableness, it too often lays the foundation for permanent mischief of a most disagreeable nature. Public men who find themselves easily affected by this beverage, should be careful to take it in only small quantities when they are likely to be placed for any time in a conspicuous position. Many a speech has been spoiled—many a sermon has failed of its effect—for want of an observance of this little caution. A celebrated barrister once complained that he had lost a cause from a too plentiful indulgence in " cups," " which," as he said, " neither *cheered* nor inebriated him." This unhappy property of tea is a very sufficient reason why it should not be taken at the commencement or in the course of a journey, especially if the weather be cold, or the individual much exposed, for then its effects are greatly increased. We attended a lady some months back, suffering from an infirmity which will never be remedied, and entirely occasioned by her having drank a large quantity of tea prior to starting on a long journey on the outside of a coach. In female schools, again, where tea constitutes an afternoon meal, the pupils are pretty sure to be taken a long walk immediately after it. Who knows what mischief may arise to future mothers from this imprudent (not to say cruel) discipline. Parents should always train their children to the common sense of these things, and to a right appreciation and observance of the simple laws of nature. Tea should never be taken in large quantity before going to bed. The chances are that it will prevent sleep, but should that not be the case, a diuretic action may follow, and the bladder be slowly distended, the sufferer not being conscious of it until his usual hour of waking, or if the body be well-clothed, an abundant perspiration may be the consequence—not only debilitating in itself, but capable, by repetition, of laying the foundation for habitual night-sweats.

THE PROFESSIONAL MOVEMENT.

Sixteen gentlemen-surgeons at Wolverhampton have petitioned against the Bill on the ground, that it does not remove the injustice inflicted by the recent Charter.—At Brighton a meeting was held on the 31st ult. in the Town Hall, on which occasion resolutions strongly condemnatory of the Bill were passed. Petitions were prepared for Parliament. The gentlemen speaking to the resolutions were, Mr. Drummond (in the chair), Messrs. Mott, Mitchell, Lowdell, Cordo Burrows, Trew, Harris, G. Weekes, Gear, and Seabrook.—On the 27th, at Tunbridge, another meeting was held—disappointment and disgust at the Bill were very strongly expressed. They insist not only that qualifications shall not be depressed but raised.—At Warrington, on the 2nd instant, a meeting was held, and resolutions here favourable to the Bill were passed; but several parts were suggested as calling for improvement.—Mr. Davis, the hon. secretary of a Medical Committee, Liverpool, has obligingly furnished us with a report of an interesting meeting held in that borough on the 8th instant. Sir Arnold Knight, M.D., occupied the chair, and the meeting was addressed by Dr. Dickinson, Dr. Watson, Dr. Inman, Dr. Sutherland, and Dr. Turnbull, as also by Messrs. Burgess, Neill, Haggerson, and Evanson. While a strong wish was expressed for the settlement of the question of medical reform—the speakers generally announced strong objection to several parts of the Bill; and censures, the most energetic, were expressed of the recent policy pursued by the College of Surgeons. Dr. Watson made some very good suggestions as to the Bill's deficiency under the head of midwifery, and Dr. Sutherland was particularly happy in his denunciation of the blunders of our Surgical College. A memorial was drawn up to Sir James Graham and accepted by the meeting—in which objections are stated to the constitution of the Council of Health on the score of its injustice to the general practitioner, to the proposed inceptorship of medicine, to the power of the Council of Health to specify what shall and what shall not be a qualification in medicine here for medical offices, to the mode fixed for registering the different grades—and to the invidious distinctions introduced into the chartered bodies. We have read the memorial with much care. The spirit of moderation, and evident partiality for the minister, in which it calls for the largest modifications of the Bill, ought, with the respectablity of the gentlemen acting, to give the document great weight with Sir James Graham.—A memorial has also been sent to us addressed to the Home Secretary by the medical practitioners of Bristol and Clifton. It is written in the spirit in which the National Association is now majestically acting, and calls for a College of Medicine and Surgery as the only means of appeasing that discontent excited so justly by the shamefully misused privileges of the College of Surgeons. At a meeting held recently at Birmingham, a report was read from a Committee favourable to the Bill in every point except in suggesting a further step towards suppressing empiricism. The Bolton Practitioners while thanking Sir James Graham for introducing the Bill, suggest all the changes our columns have been recommending. A memorial has been forwarded to us from the Isle of Man, insisting on Statutory and Collegiate preferment for all Surgeons equal to that of the Physicians. Several of the acting Licentiates of the College of Physicians—comprising among others, Drs. Clay, Thurnam, Laycock, Davies, Powell, Wintle, Prichard, Hitch, Corsellis, and Ashton, are stirring very actively to secure, that in the New Charter the extra-urban Licentiates may have their position placed on a perfect equality with that of the Licentiates intra-urban. In a judicious circular, widely distributed, they alledge strong reasons why this step should be taken by Sir James Graham, and invite a warm co-operation from their brethren. There can be no doubt that the concession of their prayer would remove one sad cause of division out of the many that afflict our unfortunate profession.—Mr. Bainbridge, of Upper Tooting, has sent us the copy of a letter addressed by him to the Home Secretary, setting out with an expression of gratitude for the Minister's kindly exertions about medical reform; he proceeds to shew that a general feeling exists for a new incorporation. That it pervades those who are not yet enrolled members of the Association, and that the restless dissentients are few, and only actuated by personal pique at their being contemptuously excluded from the honourable posts of which their discreditable characters disqualified them. He shews the *very* extended medical and surgical curricula required from their licentiates by the Apothecaries Company—of their consequent adaptation to *general* practice—the advantage of that arrangement to society; expresses his regret that the College of Surgeons, following the recent example of the Apothecaries Society, would not give up all rivalry save that of science. He concludes with a strong appeal for a change in the constitution of the Council of Health. A clever letter, signed " a Fellow of the College of Physicians," has been sent us, containing very strong censures of the new Bill as a *settled* measure of medical reform. It is so well written, that we regret we cannot further notice its contents.

THE NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS.

This Association has been indefatigable in its duties. Shortly after the expulsion of Mr. Wakley from the Committee, and their publication of the circumstance, that gentleman got up a requisition for a public meeting, and presented it to them at a meeting of the Committee. He was supported by Mr. Hillier, and Dr. Lynch, and was allowed to address the Committee. He was heard in the most chilling silence, and went off, taking nothing by his motion. The Committee told him plainly, that they would call meetings when it suited them—not him.

After considerable correspondence, an interview was had with the Apothecaries' Company on April 1st, in which the latter body expressed a very earnest anxiety to co-operate with the Association. The details of the future Charter were made matter for future consideration—the Society's abrogation of their own function being, in a great measure, made contingent on the principles recommended for the New College by the Association. On the 4th, another conference was held. It was, Mr. Fuller says, conducted in the most friendly spirit, and was most satisfactory in its results. Both sides felt that the College of Surgeons were contumacious beyond hope, and that a new incorporation was indispensible. It was settled (dependent on the members' approval on the part of the Association), that the body should be called "The College of General Practitioners in Medicine, Surgery, and Midwifery;" that the president should be elected from the present or past councillors; that the number of councillors should be 48, 24 for the town and 24 for the country: that qualification should, for men in practice, be one medical or surgical diploma; and that the first officers should all possess a double qualification. The only points of difference were, whether the franchise should be a five or a ten years' membership, and whether the councillors should hold office three or six years—points of no very essential importance, but on which the Association took the more liberal and politic view. On a subsequent conference (on April 12th), the Apothecaries' Society gracefully abandoned one point of difference—the latter, but still adhered to a ten years' franchise.

The Association and the Society agreed, that the following modifications in the Bill should be made:—

1. The total repeal of the Apothecaries Act.
2. The new Corporation to be placed on the same footing in the Council of Health, as the existing Colleges.
3. The Members of the new College to be registered in the place of the *Licentiates* under the Bill.
4. A more efficient Penal clause, which should consist of summary jurisdiction, with appeal to the Quarter Sessions.
5. The selection of Medical Officers for public Institutions to remain with the public, as heretofore.
6. No person to be admitted to examination under 22 years of age.
7. No person to be admitted to examination without testimonials of having devoted at least five years to Medical study.
8. The New class of Inceptor candidates to be dispensed with, and the clause expunged.

On the 12th instant, also, a deputation waited on Sir James Graham. This comprised the principal members of the various coalesced Associations, Mr. Bird acting as the spokesman, with a tact and success of which the deputation speak in very high terms. The following is an official statement of the interview:—

The Right Honourable Baronet stated, in the first instance, that he had already received a Deputation, accompanied by Mr. Wakley, which purported to represent the General Practitioners, and that he was informed by the gentlemen who then presented themselves, that the Committee of the National Association had not been regularly constituted, and that various other objections had been taken to its proceedings;—in fact, that it did not represent the feelings and wishes of the Members. In reply to this, it was stated to the Right Hon. Baronet, that an opposition to the proceedings of the National Association had been got up by a few individuals of extreme opinions, influenced by personal pique; that a requisition had been presented to the Committee, with a view to induce them to originate a *New* Bill, while the present ministerial Bill was under discussion in the House of Commons;—that the Meeting at which this step was determined upon, was not attended by Members of the National Association alone, but by others, and even by a body of medical students, who were allowed to vote; and that the requisitionists were few in number. The Honorary Secretary presented to the Minister a large file of letters and resolutions received by the Committee since the meeting of the requisitionists, and was permitted to read several of them, by which correspondence it was satisfactorily shown, that many of the requisitionists disclaimed the proceedings of such meeting *in toto*, having been induced to append their names to the requisition under a misrepresentation of the objects had in view; that the great body of the Members of the Association continued unanimous in their opinion, that an Institution founded on the Representative Principle, is essential to the interests of the General Practitioners of this Kingdom, and that they not only reposed the utmost confidence in the present Committee, but expressed in the most cordial manner their grateful acknowledgments for its exertions.

Sir James proceeded to admit that the last letter of the College seemed final, *too* final, and intimated his readiness to grant a charter of incorporation, if the breach could not be repaired, and that the country Practitioners and the Apothecaries Society concurred in asking for it. If the Society agreed to give up their claims to corporate existence, he gave a semi-pledge to concede the new college. In answer to Mr. Hawes, he wished the Bill to have its second reading sub-silentio, any opposition contemplated being reserved for the question of going into Committee. This arrangement seemed satisfactory, the more so, that it allowed the Association to take steps to assure Sir James Graham of the cordial co-operation of the Apothecaries Society.

A public meeting will be called immediately after the second reading of the Bill.

DENUNCIATION OF GIESSEN DIPLOMAS IN PARIS.

We, the undersigned British Medical Practitioners, resident in Paris, having had our attention directed to statements published in the London *Medical Times* of the 8th and 22d March, 1845, exposing the disgraceful manner in which the degree of Doctor of Medicine is sold by the University of Giessen, feel called upon to declare that we do not recognize, as qualified practitioners, individuals whose only title consists in the Giessen diploma; that the statements put forth in an advertisement, purporting to emanate from the faculty of Giessen, and published in the *Medical Times* of the 8th March, are unfounded; for it is a notorious fact, that constituted as that faculty is, any person however ignorant, or uneducated, may obtain from it the degree of M.D.

We also declare that the assertion contained in a letter, signed "John Bond" (see *Medical Times* of the 8th March), stating that "*many of the English practitioners in Paris have obtained the Giessen diploma through his means*" is untrue: and that, to our knowledge, only one individual practising in Paris possesses that diploma.

(Signed) Robert Alexander Chermside, Fellow Royal College of Physicians, London, M.D. Edinburgh, Physician to her Majesty's Embassy, Paris, K.C.H., K.R.E., K.L.H., &c., authorised by Royal Ordonnance to practise in France.

D. Mac Loughlin, M.D., Edinburgh, 1810, Knight of the Legion of Honour, and authorised by Royal Ordonnance (1821) to practise in France.

John Gunning, Fellow of the Royal College of Surgeons, London, Inspector-General of Army Hospitals, late Surgeon to St. George's Hospital, London.

Charles Higgins, M.D. Edinburgh, Physician to the Irish College in Paris, and authorised by Royal Ordonnance (1832) to practise in France.

J. F. Olliffe, M.D. of the University of Paris, late President of the Parisian Medical Society, Member of the Anatomical Society, &c.

Thomas Davison, M.D. Edinburgh, 1831, Licentiate of the Royal College of Physicians, London, 1832.

Daniel M'Carthy, M.D., of the University of Paris, late House-Surgeon to the Parisian Hospitals, President of the Parisian Medical Society.

J. C. Donnellan, M.D. of the Faculty of Paris.

Robert Verity, M.D.

Belfield Lefevre, M.D. (University of Paris.)

F. W. S. Packman, M.D. E.

Edmund Skiers, M.D., Paris, 1824, Licentiate Practitioner of Medicine, London, 1822, Fellow of the Royal College of Surgeons, Member of the Society of Apothecaries' Hall, London, 1820, Licentiate Practitioner of Midwifery, Edinburgh, 1819, &c.

REVIEWS.

Bibliotheque du Medecin Praticien, or, A Resumé of all the works on Clinical Medicine and Surgery, and of the various Monographs—ancient and modern—on Practical Medicine and Surgery, which have been published in France or Foreign Countries. Conducted by a Society of Physicians and Surgeons under the superintendance of Dr. Fabre, author of the "Dictionnaire des Dictionnaires de Medecine," editor of the "Gazette des Hôpitaux," &c. &c.

Before commencing anything like a review of this book, so remarkable for its research and erudition, it may not be amiss to give a short statement of the reasons which led to its composition.

It has long been a *desideratum* with professional men—the young as well as the old—the actively employed as well as their less busy brethren—to possess some work which would present to them in a compendious shape all the latest improvements in medicine and surgery. The task of reading all the medical periodicals which appear containing these improvements, is an impossibility to all classes of medical men: want of time preventing some, and want of pecuniary means debarring others from that gratification. Anxious to supply this deficiency, Dr. Fabre, on the completion of his "Dictionnaire des Dictionnaires," set about the task. Nor did he confine himself solely to giving an abstract of all modern works of merit; he enlarged the undertaking by determining to give the substance of every ancient memoir or monograph which treated medical or surgical subjects with talent, or contained anything really useful in promoting the practical part of the science of the profession to which he belongs. The advantages likely, nay, which must ensue, to medical and surgical science by the adoption of this latter plan are incalculable. While we bear in mind, that it is by modern observation and experience that medicine has attained its present exalted station, we must never be so ungenerous as to forget, that to the ancients we are indebted for the rudiments of knowledge of that science which we have now carried to such educational perfection.

Buried beneath the dust of centuries, monographs lie entombed, written by authors whose names the world of science has never heard, has never been familiar with—monographs

which, notwithstanding the neglect they have experienced, are in many instances of incalculable benefit in elucidating the darkness of medicine or surgery. In calling these again to life, and placing them in a French garb before his professional brethren—to many of whom the language in which they are written must render them perfectly useless—the editor of the "Bibliothèque" is of opinion that the character of the wor will be raised, and its reputation materially enhanced.

To attempt to give anything like an analysis of its contents would be at present impossible. We must therefore be satisfied with summing up the articles treated of in the chapters of the different parts of this work which have already appeared. Seven parts—three form a volume—have been published, the first four of which, along with a portion of the fifth, are wholly occupied with the history and treatment of female diseases. These are divided under two heads—comprehending many sub-divisions—each of which is treated with that minuteness which the importance of such subjects requires.

I. Diseases of the genital organs: 1° Of the external organs; 2° Of the perinæum; 3° Of the internal organs; (a) Of the vagina—in this chapter the author, after describing its malformations, enumerates at length the various diseases to which this part is subject; (b) Of the uterus—here are described the value and utility of the speculum uteri, its mode of application, the counter-indications against its use, and the treatment after employing it—percussion and mensuration of the uterus, and the use of the stethoscope—the errors of diagnosis and their sources, the various kinds of pessaries, and the diseases in which they are useful; diseases of the cervix uteri; 4° Of the tubæ fallopianæ; 5° Of the ovaries. II. Diseases of the mammæ and nipples. III. Diseases generally attributed to lesions of the circulation or innervation; such as, 'amenorrhœa, dysmenorrhœa, vicarious menstruation,' chlorosis, hysteria, nymphomania, &c. Finally, in a supplementary article, is given a description of an affection denominated by Dr. Jobert de Lamballe, "dropsy of the cervix uteri," but which in the author's opinion is a species of uterine catarrh.

The remainder of the fifth, the sixth, and seventh parts contains the commencement of the description of diseases of the urinary organs, divided as follows: Diseases of the kidney, its infundibula and pelvis, of the ureters, and of the bladder. The article "calculus" comprises all the improvements which modern French surgery has suggested for its treatment, and plates are added to give the reader a correct idea of the various instruments and their varieties, employed in lithotrity, according as the operation may require to be performed on adult males or females, children or old men.

In the remaining parts (which will follow each other in rapid succession) the diseases of the urinary organs will be terminated; after which will appear complete treatises on the following subjects: midwifery, diseases of children, legal medicine, syphilitic disorders, cutaneous affections, diseases of the eye, operative surgery, therapeutics and materia medica; with a dictionary of the terms employed in medicine, and a practical formulary.

The advantages of such a work are obvious without any notice. Its conductors, determined that no memoir or treatise shall find a place in it which is not really and practically useful, have resolved also to publish it at such a price as shall place it within the reach of the humblest member of the profession. They may without fear of contradiction assert, that the published parts of their work have already made an honourable character for it, which we trust will be further exalted by the merit of the forthcoming series. With a feeling of pardonable pride they may refer to the *dictum* of the University which has made their work a class-book in the different French faculties of medicine, and the preparatory schools of medicine and pharmacy throughout the kingdom.

A History of British Fossil Mammalia, and Birds. By RICHARD OWEN, F.R.S., F.G.S., &c. Van Voorst, London, 1845.—PARTS I-IV.

None but they who are conversant with the subjects which he was destined so admirably to illustrate, who knew something of their previous history, and of our imperfect knowledge respecting them, can estimate aright the labours of the immortal *Cuvier*, and the magnitude and the splendour of the services which he has rendered to the cause of the Natural Sciences. His noble contributions to Comparative Anatomy, Zoology, and Palæozoology,* a science which Cuvier may almost be said to have created,—constitute a proud and imperishable monument of his exalted and comprehensive genius, of his indomitable zeal and industry. We never utter the name of that truly great and admirable man; we never look upon the fine portrait beaming with intellect and beneficence, which adorns the walls of our library, without feelings of veneration, peradventure too strongly savouring of the fervour of idolatry,—without paying to the memory of the illustrious dead, the instinctive homage of a spirit which has never yet offered up a polluted incense upon the altar of the world's idols, and never yet bent at the tinsel shrine of worldly power or grandeur.

Upon the same commanding eminence, at the head of the order *bimanum*, stands, in our estimation, the venerable and the venerated *Humboldt*. For in our perhaps, not very courtly or orthodox, but purely scientific arrangement of that aristocratic order of the Mammiferous class, conventional distinctions of rank, must invariably yield precedence to the loftier claims of inborn power and greatness, the aristocracy of birth and fortune, to the inborn aristocracy of talent.

There is yet another name which never meets our eye, or escapes from our lips, without exciting equally profound emotions of respect, and eliciting the same forvid expressions of admiration mingled with, and exalted by the proud recollection that the bearer of the honoured name, is a native and denizen of our own glorious, but as respects the patronage of the sciences, most grievously neglected country. That is name RICHARD OWEN; a man who, if sustained and fostered, by the munificent hand of his Sovereign and her government, in a spirit of liberality at all commensurate with his genius and deserts,* would achieve for the scientific reputation and the literature of England, more than Humboldt has achieved for those of Germany, or Cuvier for France.

The four parts of the work by which this train of reflection has been excited, form the commencement of a volume which emanating from such a source, every enlightened Geologist will hail with pleasure, and peruse with avidity and interest. They contain elaborate notices of twenty-nine species of *Mammifera*, belonging to the orders, *Quadrumana*, *Cheiroptera*, *Insectivora*, *Marsupialia*, and *Carnivora*, and discovered in the supra-cretaceous formations of the British Islands. They are illustrated by numerous engravings, of the fossil remains of the various animals, got up in the style of excellence, so strikingly characteristic of the illustration of all the scientific treatises which have issued from the press under the auspices of the same spirited and enterprizing publisher; and bear the impress of the master-hand of the most distinguished Comparative Anatomist of his country and his age.

Upon the appearance of the remaining part of this most valuable work, we shall with pleasure, resume our critical labours, and exhibit to our readers, a slight but accurate analysis of the many important palæozoological facts which it contains, and a general view of the comprehensive and profoundly philosophic spirit with which some of the obscure and difficult parts of the subject have been reasoned upon, and illustrated, by Professor Owen.

* The term Palæontology is, as commonly as incorrectly, employed even by the most learned Geologists, to designate the science of fossil or extinct *animals*. Professor Owen has, himself, more than once, fallen into this laxity of expression. The following extract from the specimen of *An Hexaglot Dictionary of Geology*, lately transmitted for our inspection, by a Physician of Birmingham, will at once demonstrate the grounds of our objection to the term as so applied, and explain the origin of *Palæozoology*, now first, we believe introduced by that writer, into the scientific language of his country.

Palæontology Synonymes.—Lat. palæontologia, (ancient, a being, a discourse)—Fr. paléontologie, paléontologie — Ital. paleontologie — Germ. die palæontologie, literally a *discourse* upon *ancient beings*; but ordinarily employed, by British and Continental Geologists, to designate the science of, or a treatise on fossil *animals*. Yet as the term is alike applicable to all organized bodies, vegetable and animal, *Palæontology* is obviously susceptible of a more extended signification than it has heretofore, generally borne; and will thus comprehend both *Palæophytology*, the science of fossil plants, and *Palæozoology*, the science of fossil animals. In this more enlarged sense, it is in fact, employed by the best French and German scientific Lexicographers, by our learned Professor Ansted, and Dr. Humble. See Jourdan, *Dictionnaire des Termes, usites dans les Sciences Naturelles.* Art. *Palæontologie*; Krause, *Etymologisches Medicinishes Lexikon*; Art. *Palæontographie*; Ansted, *Geology*, vol. 1. page 248; and Humble, *Dictionary of Geology*; Art. *Palæontology*."

* "Hath not Professor Owen," we hear some patriotic reader exclaim, "had a most liberal stipend lately conferred upon him by our liberal Premier?" Some paltry two or three hundred pounds a year, we reply: a sum barely sufficient to purchase alcohol and glass for the conservation of the Professor's Zootomical and Zoological specimens; and, peradventure a trifle more than that with which the titled and luxurious aristocrat of our land is accustomed to remunerate the gastronomic services of his pampered French or Italian man-cook. Let us contrast with this ignoble pittance, the emoluments and the honours so profusely lavished by our government and senate, on the *Raptores* of the law, and the *Feræ* of our fleets and armies; and well may we indignantly inquire:—Are the brightest luminaries of science, the best friends and benefactors of the human race, less worthy of countenance and encouragement, in an educated and Christian land? Can we, moreover, forget the unworthy treatment which the widow of the illustrious John Hunter experienced in her day of bereavement and desolation, from the rulers of just and generous, and enlightened England? Gentle reader, ruminate well upon those humiliating, these disgraceful facts: "and, if thou have one blush to spare from thine own manifold follies and infirmities, be patriotic, and blush for thy dishonoured country."

Elements of Comparative Anatomy, designed especially for the use of Students. By RUDOLPH WAGNER, M.D. etc. Edited by Alfred Tulk, M.R.C.S. London, Longman, Brown, and Co. 8vo., 1844. Parts I. to III.

The want of a good elementary work upon comparative anatomy in the English language,

has long been felt and deplored by the student of medicine and the scientific zologist. Divers valuable publications, illustrative of the structure of lower animals, have, it is true, since the commencement of the present century, issued from the press of England. But, in general, these treatises have beed too elaborately and profoundly written for the puposes of elementary instruction, or too voluminous, and consequently, too expensive to be possessed by those for whose guidance and information they were, or should have been, especially composed. The almost only work,2, to which these objections do not apply, is rendered of comparatively little value, as not embodying the latest facts, and discoveries of zootomical science.

Under such circumstances, Mr. Tulk has in our opinion conferred a signal benefit upon the scientific literature of his country, by contributing to it a clearly-written and readily accessible epitome of all the knowledge accumulated to the present time, on the subjects of which it treats. The original *Lehrbuch der Zootomie* of Dr. Wagner, we have not yet had an opportunity of perusing; but Mr. Tulk's translation bears internal marks of having been executed with extreme care, correctness, and fidelity. Of the three *parts* now before us, the *first* forms a complete manual of the anatomy of the *Mammalia*; the *second*, of birds; the *third*, of reptiles. A *fourth part*, exclusively devoted to the structure of fishes, will complete the anatomy of the whole series of the vertebrata. Mr. Tulk then proposes to publish a small Atlas illustrative of the more striking peculiarities of structure, not in any one "class," we presume, as he has inadvertently written it; but in all the four classes of osteozoa or vertebrated animals. The value of this atlas will greatly depend upon its being published at the lowest price, consistent with a clear and accurate execution of the figures.

There is one very interesting subject of investigation to which we have long been anxious to direct the attention of comparative anatomists more auspiciously situated than ourselves, for the successful prosecution of such an inquiry. It has been stated as a remarkable fact in Zootomical Science, that, with one solitary exception, all the *Mammifera*, from the lofty-headed giraffe to the short-necked hog and whale, possess exactly seven cervical vertebræ. That exception is the Ai, or Three-toed Sloth, *Bradypus tridactylus*, which is expressly described by Cuvier and Wagner, 3, as furnished with nine distinct osseous pieces in the cervical portion of the vertebral series. Now, the well-known zoologist, Professor Bell, assures us that, in two skeletons of *Bradypus tridactylus* possessed by him, he has already made out the rudiments of two pairs of ribs, in the form of small elongated bones, articulated to the transverse processes of the two posterior cervical vertebræ.4. This peculiarity, if incontrovertibly established, would confer upon the vertebræ in question, a dorsal character, and, thus, by reducing the several pieces to the normal number, restore the three-toed sloth to the normal type of mammiferous structure. But the correctness of Professor Bell's description has been subsequently controverted, or denied by a French Zootomist, whose name we do not, at this moment recollect. Here the matter, at present, rests, and for the definitive settlement of a question so exceedingly interesting in comparative anatomy, we feel no ordinary solicitude.

It is, perhaps, not generally known by British Zootomists, that the *Manatus* and *Rytina*, among the Phytophagous cetacea, deviate from the common type of structure exhibited by the skeleton of the *Mammifera*, in possessing only six cervical vertebræ. This interesting fact, of which we were previously cognizant, has been confirmed, in the first part of the present work, on the indisputable authority of Professor Wagner.

1. A translation of the first two volumes of Cuvier's *Leçons d' Anatomie Comparee*, Home's *Lectures on Comparative Anatomy*, valuable only for the fine engravings with which they are illustrated; Lawrence's concise but masterly *Introduction*; Gore's translation of Carus' *Lehrbuch der Zootomie*; Grant's *Outlines*, and Todd's well-known and justly admired *Cyclopædia*, yet unfortunately incomplete, are the principal Zootomical works, worthy of enumeration here.

2. Lawrence's translation of Blumenbach's *Handbuch der Vergleichenden Anatomie*. A second and improved edition was published by Coulson, in 1827.

3 C'est (L'Ai) le seul mammifere connu jusqu, a, ce jour qui ait neuf vertebres cervicales. Cuvier, *Regne Animal*, 1 tome, 1 p. 285. See, also, Tulk's *Translation* of Wagner, Part 1. p. 9.

4 Todd's *Cyclopædia of Anatomy and Physiology*, Vol. II., p. 49.

Memoir on the Sex of the Child as a Cause of Difficulty and Danger in Human Parturition, By J. G. SIMPSON, M.D. F.R.S.E., Professor of Midwifery in the University of Edinburgh, Physician to the Edinburgh Maternity Hospital; Vice Præses of the Medico-Chirurgical Society, &c. Octavo pp. 55. Edinburgh 1844.

It is now some time since our attention was directed to this very able and most elaborate enquiry into the difficulties of labour in connexion with the sex of the fœtus. The question has long been looked upon as a matter of fact in obstetrical science; but mere assertion is not proof, and therefore it has been reserved for Professor Simpson to place the subject beyond the slightest suspicion of doubt by statistical demonstration, in which that gentleman has displayed a zeal and depth of research seldom equalled, and certainly not surpassed; and we earnestly recommend the perusal of this excellent pamphlet to every member of our profession who has a taste for information; to those who have not, it would in a great measure be useless. It is extremely difficult in reviewing statistical questions on medical subjects, to select portions for particular notice; for like a woven fabric every thread is so dependent on the whole, that it is as a whole it should be considered.

At first sight, the question here mooted appears one of no great importance, and so many may without reading this essay think it, but if they will only give it a fair portion of their time, they will find it one of immense importance; to prove which, we shall give an extract or two from the practical inferences at the conclusion of the pamphlet.

"Upwards of 7,000 deaths in all, namely, above 6,500 of the deaths of infants, during and after birth, and 500 of the deaths of mothers in childbed occurring annually in Great Britain, are referrible to the direct or indirect agency of the cause that we have been discussing, viz., the sex and larger size of the head of the male child."

Another quotation equally startling is this—

"Under the signification and reservations which we have thus stated, we repeat that the greater size of the male fœtal head is the more or less immediate *cause* of a large number of those maternal and infantile deaths that take place in connection with labour, or as a result of that process. In illustration of this remark, I shall venture to add another observation—one which may at first seem sufficiently startling to those who have not practically directed their attention to the subject, though it is but a simple and direct deduction from the facts we have so imperfectly brought forward in the preceding pages. It is this.

The official returns of mortality of England and Wales have only, as yet, been collected for somewhat upwards of seven years, viz. from July 1st 1837 to the present date. If the calculations we have already given are accordant with truth (and we believe them to be within the limits,) there have been lost in Great Britain during that limited period, as a consequence of the slightly larger size of the male head over the female at birth, about 50,000 lives, including those of about 46,000 or 47,000 infants, and between 3,000 and 4,000 mothers who have died in childbed."

It is indeed a question of importance; *that is*, if the sacrifice of upwards of 100,000 beings in little more than seven years, can make it important. The pamphlet before us is full of tables proving this interesting point which would occupy too much space to copy here; suffice it to say, that the calculations are founded on large numbers which increase their value. The subject is divided into four great divisions:—

First.—"The dangers and difficulties of parturition are greater to the mother in male than in female births; proved by two propositions."

Second.—"The dangers and accidents from parturition and its results, are greater to the child in male than in female births; proved by seven propositions."

Third.—"Causes of the greater maternal and infantile danger and fatality accompanying the birth of male children."

Fourth.—"Reasons for considering the greater size of the head of the male child as the cause of the greater number of complications and casualities accompanying male births." The work concludes with, "Practical inferences and extent of influence exerted by the male sex of the infant upon the general maternal and infantile mortality during parturition and for some time subsequent to it."

We are quite certain, enough has been said to prove that this little work ought to be in every medical man's possession, as a valuable record of most interesting facts extensively illustrated, and every way worthy of its most indefatigable author.

PENCILLINGS OF EMINENT MEDICAL MEN.

LIZARS.

It may be very problematical whether there be or has been for a number of years past, one well educated man in the profession of medicine in any part of the civilized world, from whose lips "*Lizars of Edinburgh*" has not been frequently lisped; or to whose ears "*Lizars of Edinburgh*" is not, or has not been as familiar as the expression of "*the Lord Mayor of London*" to the ear of a cockney. Perhaps no professional name has been more buzzed abroad than that of *Lizars*. It has obtained a singular netoriety: he is a singular *little* man, (we beg his pardon—we wot he calls himself a *middle-sized* man—but what *little* man ever came short of that convenient standard in his own estimation, and that probably, from his having once or it might be twice in the course of his life, seen a less man than himself?) He is also singularly independent in his way, singularly talented, and when our friends have become as fully acquainted with him as we shall presently make them, from sources that cannot be disputed, we *calculate*, (as our Transatlantic brethren would say) they will estimate him as highly as we do ourselves, and perhaps be disposed to consider that blame attaches to us in withholding to this rather late period, our pencilling of this extraordinary character and meritorious man.

John Lizars has a younger brother, *Dr. Alexander Jardine Lizars*, who was for a long time an eminent Lecturer in Edinburgh, and is now the Professor of Anatomy in Mariachal College and

University, Aberdeen, and both sprung from the late Mr. Daniel Lizars, an artist in Edinburgh, who occupied a highly respectable position in what is called the middle class of society there, was much esteemed by all who knew him, and considered to be very eminent in his profession. He was moreover a shrewd man; looked upon his *wee Johnny* as a remarkably clever boy, and thought if he were but well educated, he would make an excellent doctor. Others were of the same opinion, and acting under this impression, the father put the boy to a common grammar school at a very early age. As soon as it was supposed the change would be advantageous to him, he was removed from that seminary, and in 1800 placed in the High School. When he thought proper to apply himself, he made the most rapid progress in his education, displacing his schoolfellows as if they had been so many unresisting *nine-pins* before the ball to which he applied his powers. But, as we have said, this was only *when he thought proper*, for he was a youth of some whims. In those days he seemed to act as if under an impression that unremitting application might injure his *precious* intellect; and accordingly he adopted different lines of conduct, and so alternating and opposed to each other were the varied characters that he assumed, that his teachers were sometimes nearly impressed with the idea that he must have as many varied qualities of brain contained within his own single skull, as the cameleon is capable of exhibiting colours. At one time, as we have said, he would leave his class-fellows in his rear at the most difficult tasks, as if those tasks had been mere toys for his amusement. At another time he was dull, stupid and deaf. It is said that one man may lead a horse to the water, but that ten men cannot make him drink; so neither on those latter occasions could the stentorian lungs nor the *taws* of Johnny's schoolmasters make him hear when once he had determined to be deaf. At another time he was the regular *booby* of the school; and until his pranks were exhausted in that character, it was of no use to attempt to instruct him in any thing. But his grand character of all was, that of *pugnacity*. If there was a *bicker* between any two, or any number of the boys, any person in the school, master or pupil, was always quite safe, in offering ten to one in favour of Johnny Lizars being, if the not the sole originator, at least the main promoter of the strife. If there was a fight on any day of the week, or a dozen of fistic contests in the course of a week, if Johnny was not the starter of the game, if he was not head foremost in the battle himself, as certain as the fight took place so sure was it that he would at any rate be bottle-holder to one of the combatants; nor mattered it much to him if he held a bottle in each hand for each combatant, and presented a knee to each to rest upon during their reviving intervals, so long as he was only sure of the spree going on. One ever-to-be-remembered day however by him, (and which he himself tells of to this hour) his prowess overshot the mark in this department of his science, and brought upon him a reward that he had as little stipulated for as it was welcomely received by him: he saw the late celebrated John Bell, (the very man who afterwards became his honoured and most useful preceptor,) passing near to the school when there had been a heavy fall of snow. He immediately thought that that presented one of the best opportunities he might ever meet with of letting the *Doctor* know what the boys of the High School were made of. Accordingly, in a shorter time than probably the Duke of Wellington ever had a regiment under arms, after he had issued his order for it, he had a company of assailants assembled, with whom he attacked (himself being, as a matter of course, at their head) Mr. Bell with snowballs in the most unmerciful manner. Mr. Bell has been since heard to say, he thought he never should have got off with his life on that occasion, or, at any rate, without having had his eyes knocked out. The affair, of course, did not rest there. A formal complaint was transmitted to the master of the boys; the commander-in-chief was ordered to come forth; he was led into the large hall of the school, like a soldier to the halberts; the other boys were ordered to assemble around him; and there, in the presence of them all, Lizars received one of the most tremendous public floggings that any boy in the school was ever known, either before or since, to have had inflicted upon him. Sufficient only for the day was the evil thereof; the offence and the punishment both passed over, and were forgotten; but the courage of Lizars was nothing daunted, for, as long as he afterwards remained at the school, he was still to be found, as formerly, the gallant leader of every affray. Nevertheless, with all this enamouring for the fistic art on the part of Johnny, he was a kind-hearted, affectionate, generous lad, and greatly beloved both by his masters and fellow-pupils. He never wished to see others knocking each other about; but if the least necessity appeared to him for it, he was always ready himself to enter the ring; but the moment he had defeated his opponent, he was the first to wipe away the tears of the fallen, to sympathize with him, and to cheer him up with the prospect of himself being a successful combatant on some future day.

At length, having got through all his conflicts at the High School, with the character of an excellent scholar, he left it in 1804, and immediately entered the classes in the University of Edinburgh. About the same time, being then of the age of fifteen years, he was articled as a pupil to John Bell for five years. Mr. Bell soon saw that he was a talented young man, and he pushed him forward in his medical education in every possible way. It was early intended that he should become a lecturer on anatomy and surgery; therefore a great proportion of his time was at first spent in the dissecting-room. Mr. Bell also afforded him the most ample opportunities of learning the other branches of his profession. He very soon became a great favourite. Bell allowed him to see all his practice, and latterly took him into the situation of assistant to him in his operations. The best proof of the manner in which he conducted himself, the satisfaction he gave to Mr. Bell during his apprenticeship, and the opinion that gentleman formed of him, is to transcribe here, from Mr. Bell's own handwriting, his endorsement on the back of the articles of apprenticeship:—"I hereby discharge the indenture of Mr. John Lizars, who has served me faithfully during his apprenticeship of five years, and shewn himself, at the same time, diligent in all his studies, and sincerely devoted to his profession. I know Mr. Lizars to be thoroughly skilled in anatomy, chemistry, and all the essential studies belonging to his profession. He has, under my tuition, seen and assisted respectively in all the operations of surgery, has attended the patients, and witnessed all my methods of practice; and I declare that I know no young man more perfectly capable of all the duties of his profession. There is no operation of surgery which I would not willingly stand by him and see him perform; and in all the lesser duties of his profession, he is at once skilful and diligent; so that I should regard him, in every sense, a valuable acquisition in private practice, or in any department of the public service. I need hardly add that I wish him success and happiness in the world, and an honourable station in his profession, with all the sincerity of a true and constant friend. "JOHN BELL.

"Edinburgh, 9, George-street."

In 1809 he obtained his diploma from the Royal College of Surgeons in Edinburgh, and almost immediately afterwards came to London. Here (having prepared himself for them) he underwent examinations at the Royal College of Surgeons, and also at the Navy Medical Board, and sailed in the same year of 1809 to the Mediterranean, as an assistant-surgeon in the Royal Navy, where he saw extensive practice, especially in the treatment of gun-shot wounds.

While in that service he proved himself to be a most indefatigable and zealous officer. When on the coast of Spain he became a favourite with General Saarsfield, of the Spanish Army: so much did that general become attached to him, and so high an opinion did he form of his skill and conduct, that he applied to Lord Exmouth, who was then the commander-in-chief on the Mediterranean station, for permission to have him to be surgeon to his own division; but Lord Exmouth would not part with him, and refused the general's application. When at Malta he visited a great many patients affected with the plague, and pressed for permission to attend such patients during the epidemic; but so ably and satisfactorily did he discharge his duties in the office he then held, and so important were his services there, that Lord Exmouth also refused to comply with that request. Drs. Burnett and Weir, Medical Commissioners of the Royal Navy, state "that Mr. John Lizars' ability in practice has proved him equal to the duties of any rank or station in his profession;" and Dr. Burnett, in writing of him, further says, "that while he" (Dr. B.) "was serving in the Mediterranean as physician of the fleet, and inspector of naval hospitals, he was personally acquainted with Mr. Lizars, and formed the highest opinion of his talents and private character, which secured him the approbation and support of the Right Honourable Lord Viscount Exmouth, then commander in-chief on the above-mentioned station."

At the conclusion of the war in 1815, he returned to Edinburgh on half-pay, after an absence of six years, became a Fellow of the Royal College of Surgeons, Edinburgh, and commenced to lecture there as a private lecturer on anatomy and physiology; also to teach practical anatomy, and to practise as a surgeon. He had a large attendance of students both at his general and practical classes of anatomy. Within an incredibly short period he possessed himself of a museum containing a collection of morbid preparations, casts, and drawings, which was often declared by visitors not to be excelled by any private museum in Great Britain; and when surprise was expressed at the magnitude and value of his collection, his observation generally was, that in five years he would undertake to make a museum of pathological anatomy equal to any in Europe. As a lecturer, he was winning, courteous, and instructive. His delivery was distinct, animated, and impressive; and men who now hold some of the most distinguished appointments were his pupils.

In 1821, after a warm contest, he was elected Professor of Surgery to the Royal College of Surgeons, Edinburgh, by a considerable majority of the votes of its fellows. In that contest he defeated Professor Syme, who strained every nerve to obtain the office; and at that time he resigned his classes of general and practical anatomy to his brother, Dr. Alexander. About the same period he was appointed to be one of the surgeons of the Royal Infirmary. Liston was then also flourishing in Edinburgh, and it was the boast of the Edinburgh School, that at that day its surgery was equal, if not superior to that of Paris or London. Liston excelled in lithotomy—Lizars in tying the arteries for aneurism. We well remember seeing every spectator (and they were not few) struck with perfect astonishment at the coolness and dexterity Lizars displayed in deligating the arteria innominata. That was the first time in Great Britain, and only the *third* time in which "*the bold operation of tying the arteria innominata*" (as Mr. Syme, in his work on surgery, expresses it), the second largest artery in the body, had ever been performed. It was performed first in 1818, by Mr. Mott, of New York; secondly, in 1822, by Dr. Graefe, of Berlin; and thirdly, by Lizars, in 1837. According to the publications of that day we find it stated that "Lizars lays down an important axiom, viz., 'that the arteria innominata ought never to be secured, because the subclavian artery remains distended with blood, and acts on the deligated point of the arteria innominata, and produces ulceration and hemorrhage.' Lizars showed himself to be, in other respects, a dexterous operator, a good pathologist, and most accurate in diagnosis." It sometimes amounted almost to an amusement to witness the zeal with which Lizars and Liston vied with each other in performing *catheterism* in severe cases of stricture, and neither would resign the palm to the other. When Liston left Edinburgh, Lizars became the senior operating surgeon to the Royal Infirmary.

From the registrations of the University and College of Surgeons, we find that the entry of students for the University in the session of 1831-2, was 1,902; that to the College of Surgeons for the same session, 810; and that from that period,

down to 1841-2, the entries to both uniformly decreased, until, at the latter session, they were—to the University, 1,002, and to the College of Surgeons, 320. In consequence of this falling off of students to the Edinburgh school, it is a known and admitted fact, that every kind of means, and some of the most unscrupulous character, were resorted to by several of the lecturers, in the course of those intermediate years, in order to secure classes. A system even of *under-selling* of tickets of admission to students was introduced; and these things at last became so flagrant and discreditable, that at a general meeting of the extra-Academical Lecturers, called for the purpose of taking the subject into consideration, Lizars and Dr. Thatcher were appointed a committee to wait on some lecturers, and to remonstrate with them respecting the unfair means they were adopting to obtain students. Nothing satisfactory, however, was the result; and, disgusted with the system that was thus introduced, and openly carried on, in teaching so important a science, Lizars could not condescend, as he expressed it, to become *one of those paltry jobbers*. He therefore determined to separate himself from that class of persons altogether, and accordingly, in 1840, ceased to deliver lectures; and from that cause the rising generation has to lament that it lost the advantages of one of its most efficient teachers.

In the summer of 1842 he became a candidate for the chair of Professor of Surgery in the University of Edinburgh, then vacant by the death of Sir Charles Bell, but he was defeated on that occasion by a very young gentleman, named James Millar. What could have induced the electors to have rejected the tendered services of a man so pre-eminently qualified for the chair as Lizars, we are quite at a loss to conjecture, and have never been informed; but of this we are thoroughly convinced, that if ability and merit in a candidate, universally attested to, and the conservation of the health of mankind, are points which ought to be considered in the choice of a Professor, the election of that day ought to deprive my Lord Provost, Magistrates, and Town Council of Edinburgh from ever having the power again to do such violence to science.

As an author Lizars has written extensively, and through that means has spread his fame to the remotest corner where surgery is known as a science. His contributions to the *Edinburgh Medical and Surgical Journal*, the *Lancet*, in its better days, and *Ryan's Medical and Surgical Journal*, have been numerous. In the *Edinburgh Medical and Surgical Journal*, there is an original paper of his on *Inflammation*, a paper on *Hernia*, and a description of *his excision of the lower jaw*, an operation which he was the first to perform in Scotland. In *Ryan's Medical and Surgical Journal*, there is a description of his excision of the *upper jaw*, an operation which we believe we are accurate in saying he was the first to perform, not only in Scotland, but in the world! At the time he performed that great operation, from the numerous connections of the jaw, and the important parts by which it is surrounded, the attempt to remove it was not only ridiculed by the profession, but scouted as being not only altogether impracticable, but most unwarrantable to attempt. Nevertheless in the teeth of such opposition and discouragement, he undertook it; it was completely successful; and he was not much older till he had to perform it in two more cases. That disease, therefore, which had theretofore been considered incurable, and absolutely fatal, has been proved by the success of his operations, and also of those which have subsequently been performed by Liston, Syme, and Ferguson, in similar cases, to be within the reach of the healing art.

He is besides, the author of a *System of Practical Surgery*, with an Appendix on the operations for the great cure of *Squinting* and *Clubfoot*, which have been greatly approved of. But his crack and crowning work, and which has secured to him commendation from every quarter of the globe, is his *System of Anatomical Plates*. He, himself, planned that most beautiful work; he conducted the whole of the dissections represented in it; personally superintended all the drawings, some of which he made himself; wrote the whole of the descriptive parts with his own hand, and all the physiological, pathological, and surgical observations that are given to the world there. The fame of the work, as every one who has seen *the unique thing*, may well suppose, spread like wild-fire. *Two thousand eight hundred* copies of the first edition of it were sold at £12 12s each copy, and it has been ordered from the Cape of Good Hope, India, China, the Mauritius, Australia, Gibraltar, the Mediterranean, Canada, and the United States. When it made its appearance, the Press (medical and non-medical) teemed with approbation, and few names known to surgical fame forgot to make the author gratifying acknowledgments.

Lizars' renown therefore as an anatomist, a successful operator, and an accomplished surgeon, stands in the very first rank not only in Britain but in all other countries. He is corresponding member of the Society of Emulation of Paris, Honorary Member of the Society of Medicine of New York, with an interminable list of *etceteras*.

The fiftieth summers' sun has now passed over his fair head, but he is as vigorous and active as he ever has been. He is somewhere about five feet seven or eight inches in height, and moderately stout. His hair is of a dark brown, shewing a disposition to form a tonsured crown to live at no very distant day. His complexion is fair and ruddy, his forehead elevated, his features moderate in size, his countenance frank and open, his demeanour courteous, his manners most gentlemanly. On being introduced to him, one would take him to be a good humoured, friendly, private gentleman; one who could neither himself inflict, nor endure to witness inflicted by another, the slightest wound on a fellow-creature, although he is the man who, as we have shewn, has performed the most appalling operations with an unshaken nerve, and with as much *sang froid*, as if he had at such times been assisting a lady to part of a *trifle*, at some evening party in Charlotte-square, Edinburgh. He is a strictly upright and honourably minded man. At the bedside, he is mild, comforting, humane, and loved by his patients, nor does he ever hesitate to peril, nor even (as indeed he has often done), to sacrifice his own health for their advantage. He is quick in detecting the nature and extent of disease and injury; judicious, prompt, and efficient in his treatment. In social society, he is the *king of good fellows*; full of fun, full of joke; and though he is fond of it, yet on principle he resists the allurements of society as much as he can, and lives in comparative retirement. We remember a dialogue that is said to have passed between a certain gentleman and his valet, on the occasion of the latter giving notice to leave his situation; one morning the gentleman on coming down into his breakfast-room after the notice had been received, said to his servant—"John, what are you going to leave for?" John replied, "Why, Sir, the truth is, that I cannot bear your temper." "Poh, poh, nonsense, John," said the master, "you know I am no sooner in a temper than I am out of it again;" "Aye, aye, Sir," rejoined John, "that's very true, but the worst of it is, you are no sooner out of it than you are in it again." Now though we do not think that that same valet would have been quite so hard upon our friend Lizars, had he been his master, yet we believe he would have agreed with us, in saying, that in temper, he is somewhat *peppery*. In a moment he is in a blaze, but as soon as the flame gets vent, all is again hushed. The instant his hasty words have gone forth, he is cool; a baby might toy with him, lead him, and be his master. He forgets an injury with the same rapidity that he resents a wrong. Straightforward himself, he neither is jealous of nor suspects any man; and if we may be allowed the expression, his heart is steeped in the milk of human kindness. He is a warmly-attached and faithful friend. The needy and struggling student, never met with a more generous benefactor. No ostentation heralds his acts of charity, although no man's benevolence (in proportion to his means) exceeds his, nor can Scotland boast of a man of a more kind and obliging disposition.

He has a fair share of practice, but he is not what would be called on the Royal Exchange of London, a *rich* man. Merit is not always rewarded according to our present views of reward, and upon lately inquiring of a bosom friend of his, how it was that such a man as Lizars had not by this time amassed a fortune, the reply was, "for this known and indisputable reason, that he is a man totally devoid of all professional humbug; had he had a particle of this ingredient in his composition he would by this day have been a very rich man, but he can neither cringe nor fawn to superiors (that is, to any who may ignorantly imagine themselves his superiors), nor the powers that be; nor flatter, nor court any man from interested motives." He is not very popular with some of his professional brethren by whom he is immediately surrounded. He is too free, blunt, and natural.

He married in 1820, a daughter of William McCraken, Esq., of Lochvale, in Dumfriesshire, and there is but one thing wanted with him to render his cup of domestic happiness brimful. He is fond of children, and though a nursery is in constant readiness, Mrs. Lizars—amiable as she is—persists with sad obstinacy in denying him its *wee* tenant.

TRANSACTIONS OF LEARNED SOCIETIES

ROYAL MEDICAL AND CHIRURGICAL SOCIETY. April 8th, 1845. Dr. Watson, vice-president, in the chair.

On the Colostrum of the Cow, with remarks on that of the Human Subject, by John Davy, M.D., F.R.S., Inspector General of Army Hospitals, &c.—Communicated by Dr. Hodgkin.

The colostrum, the new milk of the cow after calving, differs, as is well known, from the ordinary cow's milk, in being of a rich yellow colour, less liquid, of greater specific gravity, and in possessing the property of coagulating when heated. On this account it has been supposed to be more animalized than common milk, and to contain serum. This inference not having appeared to the author to be satisfactorily proved, and *a priori* not very probable, he was induced to subject it to some trials, the result of which he describes.

The details of these experiments are given, and the inferences he draws from them are to shew that the peculiarities of the colostrum do not depend on the presence of serum; in short, that the colostrum is destitute of serum, and that its coagulability by heat depends on a peculiar modification of its caseous portion.

And that the caseous portion of milk does admit of no inconsiderable modification is shewn (the author observes,) in a remarkable manner, in comparing it as existing in human milk and in cow's milk; in the latter, even in its ordinary condition so readily coagulable, whilst in the former it resists this change, whether acted on by acids or rennet, and yet is easily obtained by means of evaporation when freely exposed to the air.

Physiologically considered, the most marked circumstances belonging to the colostrum are, the concentration of nutritious matter in it, the greater facility of its coagulation by rennet compared with older milk, and its greater power of resisting change when exposed to the action of atmospheric air. These, the author remarks, are qualities which may be eminently serviceable, viewing it as the first food of the young animal. Its easy coagulation may suit it to the stomach in which probably the gastric juice at first is small in quantity and feeble. Its power of resisting change and remaining semi-fluid may adapt a part of it to the intestines, to promote the removal of the meconium, while its concentration as nutritious matter may fit it to perform for the calf the same part that the substance of the egg serves, which enters the intestine during the latter stage of fœtal development, in the instance of birds, reptiles, and fishes.

The author observes, that if his inferences as to the use of the colostrum in the cow are correct, it may be expected that the first milk of other animals, at least, of those the young of which are born fully formed and vigorous, will be found similar; and so far as he has been able to learn, it is so. Whether the first milk of those animals, the young of which are helpless and feeble, as the

carnivora, is also similar, cannot be determined for want of facts, but he is disposed to conjecture that it is, having found the first milk of the bitch to coagulate when heated, and to yield a large proportion of animal matter. (35·2 per cent.)

In the carnivora it may be requisite for the first milk to be rich, as these animals have to leave their young to procure food, and to be absent, it may be, an uncertain time. In accordance with this, too, the author observes, is the fact that the human milk, the first drawn, is not unusually rich, and does not coagulate when heated; at least, such are the results of the experiments he has made, and which are given in the paper.

The author concludes by remarking that this dilute state of the human colostrum, seems equally suitable to the offspring and mother; the one helpless and feeble, not requiring concentrated nourishment—the other commonly from a certain degree of exhaustion during labour, ill-fitted to yield such a supply;—offering in this point of view another instance, to the vast number of examples of harmonious adaptation, and it may be also one circumstance more by which man, as an animal, is distinguished from every other.

Dr. Copland expressed the disappointment he felt at hearing a paper so entirely chemical, instead of a communication on a practical subject, of which there were about thirty in the possession of the society, and only four or five more nights to read them in. He should have been very glad to have read such a paper in a philosophical journal, but he thought it totally out of place in this society. The physiology of the paper, in his opinion, was not quite correct, and it was far from being generally interesting. It might be said that there was something due to the gentlemen who sent them communications, but there was also something due to the members of the society, and he thought that more care should be exercised in the selection of the papers that were brought before them.

Case of Obstruction of the large Intestine, in which the ascending colon was opened with success; the patient dying three months afterwards of another disease.—by Samuel Evans Esq., of Derby—Communicated by Wm. Bowman Esq., F.R.S. Assistant Surgeon to King's College Hospital.

Lewis Street, æt. 23, a farmer, has been liable for several years to attacks of diarrhœa. In Sept. 1843, he was seized with violent pains in the bowels resembling colic, which lasted 13 hours; about the third week in Jan. the attacks recurred and became more severe on the 5th of Feb. The author saw him for the first time on the 7th. He was suffering from severe intermittent pains in the abdomen, which was distended but free from tenderness. There was a distinct swelling in the right iliac region. His bowels had not been relieved since the 5th; opiates, active aperients and stimulating injections were administered during five days without relieving the pain or sickness, or procuring evacuations. On the 12th, and 13th, his sufferings were relieved by large doses of liq. opii. sedativus. From this time to the beginning of April, the size of the belly gradually increased; he also daily suffered many paroxysms of pain. At intervals, large quantities of flatus, and small portions of clay-coloured fæces escaped from the bowels. The patient's health became much impaired, and vomiting recurred almost daily. On the 25th of March, Callisen's operation as modified by Amussat for the formation of an artificial anus in the loins was proposed, but the patient yielded to the wishes of his friends in postponing it. The emaciation increased, and the abdomen became distended to the greatest possible degree; the evacuations entirely ceased, and the pulse became feeble and fluttering. April 9th:—the operation was performed; a transverse incision four inches long, was made in the right loin, the ascending colon was opened, and more than two gallons of semi-fluid clay coloured fæces were discharged. He recovered from the operation, and by May the 9th had gained flesh, and the wound in the intestine healed, but the evacuations escaped entirely by the artificial anus, being restrained by a plug in the orifice, which was removed four or five times a day. At the end of June he commenced passing diabetic urine, and suffered from thirst. July 2nd:—he rode a distance of 6 miles in an uneasy cart, and shortly after, symptoms of peritonitis supervened, and he died on the 5th. On examination of the body, the cause of obstruction was found to be a stricture in the colon, just beyond the angle formed by the junction of the ascending and transverse portions of the gut. The contracted part was almost as hard as cartilage, and would just admit a crow quill; its inner surface was ulcerated. The cœcum was enormously distended and nearly as large as a stomach of ordinary size; the ascending colon was also much enlarged.

The author remarks that this is the eleventh case on record, in which Callison's operation (modified by Amussat) has been performed in the adult, in consequence of obstruction in the intestinal canal. From the previous history of the case, it would appear that the disease had been of slow progress and long duration, but at the period to which the operation was delayed, owing to the interference of the patient's friends, he was in so alarming condition that it is impossible to imagine a case more unfavourable for it. Two months afterwards he was so much recovered that there appeared to be every prospect of his restoration to health, but these hopes were disappointed by his imprudence, with regard to diet and exercise; as far as the operation was concerned, the case was successful.

Sir George Lefevre observed that at all events this was a practical paper, and one of considerable interest. He was of opinion that in such cases, there was not only the mere local injury to be regarded, but that the whole alimentary canal suffered; the patient after such an operation should be kept in the recumbent position, and on spoon diet for months afterwards. The case showed what great liberties may be taken with the intestines; some time since he drew up the details of two cases, in which the intestine had been punctured, at St. Petersburgh, and had intended to lay them before the society, but he subsequently withdrew them, and published them in one of the journals. The operation was not performed with the view of producing an artificial anus, but to relieve the pain and other inconveniences caused by distension. In one of these cases, the patient, a lady of high rank, was greatly relieved by the operation, which was performed by pushing a trocar into the distended colon, but she died in about eighteen hours after. In the other case, in which the same operation was performed, and was attended with immediate relief, the patient died in twenty hours. Sir George Lefevre then enquired whether this operation of puncturing the intestine for the discharge of flatus, had ever been performed in this country, with the view of affording transient relief in those cases where permanent benefit was not to be anticipated. In such cases relief may be obtained even at the eleventh hour, as was evinced by the details of the case which had been read before the society that evening, but he thought it a question whether it was altogether advisable to wait so long.

Mr. Benjamin Phillips said there could not be any doubt as to the importance of this operation. It had been performed several times with more or less success, either to relieve obstruction in the bowels, or to remedy an imperforate anus, but as far as his knowledge extended, there had been generally a want of success attending it. The difficulties connected with it did not depend on the nature of the operation, but on the diagnosis, as it is not easy to discover the cause of the obstruction. It may be produced by an accumulation of fæces, which may exist for weeks, and yet be ultimately removed without there existing any necessity for an operation. If the obstruction were produced by disease in the rectum, by carcinoma, for instance, as was said to have been the case with Broussais, more perhaps might be said in its favor, as it would then offer a better chance of prolonging life. Even under such circumstances it might be doubtful whether the artificial anus would not prove a greater inconvenience than the existing disease. Disease in the rectum however affords a better reason for the performance of the operation, than when it is situated higher up in the intestine. In these latter instances it is difficult to ascertain the cause of the obstruction, and with regard to the case which had been just read, there was not any circumstance from which to draw conclusions as to the cause of the obstruction, whilst from the occasional passing of clay-colored fæces, it might have been regarded as caused by an accumulation of indurated fæces, instead of being a case of constriction, as it eventually proved to be. At the same time there would be a difficulty in making the selection of the part of the intestine which should be opened, as it might happen that the operation would be performed at the exact spot where the obstruction was situated.

Dr. Powell mentioned the case of an hysterical patient, who was liable to great obstruction of the bowels, which was always relieved by opiates and croton oil. The last time that obstruction existed, the bowels were not relieved for two months; injections were not of any service, but the constipation was removed by half grain doses of morphia with two drops of croton oil, exhibited night and morning, four doses being required before they took effect. He concluded therefore, that the attack of constipation was dependant on hysteria.

Mr. Davis of Hampstead mentioned the case of a man, who returned an invalid from the West Indies in the year 1800, and who was subject to attacks of spasmodic colic and constipation, for which aperients generally were inefficacious. His appetite was very good, but he occasionally rejected his food. This state would continue for fourteen or fifteen days, the man walking about the while, when it would be requisite to administer gamboge pill and small doses of the sulphate of magnesia, by which means the bowels were unloaded, and scybalous fæces discharged. In this state he would go on for about three weeks, when a similar train of symptoms would arise, and the same plan of treatment was of necessity resumed. This man continued to be subject to these attacks as long as he continued under Mr. Davis' care. In another case, that of a lady, who had been recently confined, and who was very ill from the bowels having been much neglected, he exhibited appropriate remedies, and brought away numerous scybalæ. He (Mr. Davis), mentioned these cases to show what might be effected by proper treatment in cases of obstinate constipation.

Mr. Solly thought that Mr. Phillips had very properly called attention to the difficulty of deciding in what cases it would be right to have recourse to this operation, and he believed that every one in practice must have met with in cases which they were not able to decide as to the nature and cause of the obstruction. A few years since he had seen a case in which a patient, labouring under a distended condition of the colon from a diseased state of the rectum, was tapped by mistake for dropsy, and died afterwards from peritonitis which supervened from the operation. He also alluded to cases in which the intestine was constricted by the formation of adventitious bands, as serving to complicate the diagnosis, and stated that about eleven years since he had attended a case with Dr. Sutton, of Greenwich, where he was called upon to pass a bougie. The patient died shortly afterwards, and when the body was examined after death, the colon was found to be firmly bound down and constricted by bands stretching across from the mesentery.

Dr. James Johnson was of opinion that in the case which had been described by Mr. Evans, that there could have been but little difficulty in forming a diagnosis as to the situation of the obstruction, inasmuch as a bougie could be passed very readily, and there was not any difficulty in throwing up two or three pints of fluid. At the same time the seat of the distension showed that the obstruction must be in the colon itself, and not in the rectum nor in the sigmoid flexure. The operation was, therefore, in every respect called for, and requisite. It is astonishing how long accumulations of fæces may continue without inducing serious mischief. In the case of a patient of his, there had not been any passage of fæces by the rectum for three months, and yet he ate and drank well, and was apparently in good health. The fæces were discharged by the mouth a few hours after taking food. There existed a large

inelastic tumour in the hypogastric region. He did not think there was any reason to anticipate a fatal termination in this case, and it became a question whether it would be advisable to perform the operation; and he was rather inclined to believe that an artificial anus would prove a greater source of annoyance than that which already existed.

Mr. Dunn mentioned the case of a child who was born with imperforate anus; an operation was attempted, but the colon could not be reached. After death, the body was examined, and the gut was found not to be larger in size than a crow-quill.

Mr. Blizard Curling observed that he was about to remark that it was not an easy thing to reach the colon, especially in infants when it is not in a state of distension. In one case that he had heard of, the surgeon had cut down upon the kidney, instead of the intestine. In a case of imperforate anus, in which the usual plan of proceeding was adopted unavailingly, he had proposed the operation in question, but it had not been acceded to. He had performed it, however, after death, and had found it not to be so easy as it is supposed to be. By going a little too near the spine he had come upon the kidney, and he had reason to believe that the same accident had occurred in operations on the living body. The operation might, however, be readily performed, by making the incision a little more externally, and then there would not be any difficulty in opening the the intestine, if it were at all distended. He fully agreed with Dr. Johnson in the observations which he had made on Mr. Evan case, and he said that he had never met with any instance in which the situation of the obstruction had been more clearly made out. He thought, too, that the result of the operation was such as to justify surgeons on future occasions in adopting it under similar circumstances.

Dr. Taylor said that if Mr. Evans was clear about the seat of the obstruction, he could not have done otherwise than operate, as his patient must else have died soon, and it was evident that his life had been prolonged by the proceeding. With regard to the nature of the obstruction, it had not been stated whether it was of a carcinomatous character or not; that, however, was probably a question which the microscope alone could settle. From the previous history of the case, it appeared to have been produced by simple inflammation. The patient had been subject to diarrhœa for years, which had most probably been caused by inflammation, followed by ulceration, cicatrization, and consequent contraction. Of this he had seen several examples subsequent to fever, in most of which the question as to the propriety of operating was not entertained, because the patients died of chronic peritonitis before the symptoms had assumed characters of sufficient severity to warrant such a proceeding. He had seen this contraction in diff rent parts of the bowels after fever attended by inflammation, ulceration, and contraction in that canal, and he thought it might be regarded as an useful diagnostic sign in cases of obstruction, that the disease depended on a stricture and not on a mere accumulation of fœces, if the patient had been known previously to have laboured under inflammation of the bowels.

Mr. Hilton commended the proceedings in Mr. Evans' case, and stated that cases were now and then met with, in which the obstruction was caused by a twisting of the colon on itself. He had seen a case of this kind, and had proposed the operation, which, however, was not performed, until after death, when it was effected by means of a vertical, and not a transverse incision. It extended from the false ribs to near the crista of the ilium and was parallel to the abdominal muscles. He did not experience any difficulty in reaching the colon. He then alluded to Sir George Lefevre's observations on puncturing the colon, as connected with this operation, and said there was a marked distinction between the two proceedings, as in Sir George's cases, the peritonæum was wounded, an additional risk which was studiously avoided in Amussat's operation.

Dr. Watson observed that the conclusions which he drew from what he had read and heard respecting this operation, were that in some cases it was perfectly justifiable, providing that the patient's consent had been previously obtained, and the nature of the operation, with its disagreeable consequences had been fully explained to him. In that light he regarded the case in which Mr. Evans had operated, and he thought the adoption of that proceeding fully warranted by the history of the patient. On the other hand, the case which had been narrated by Dr. Johnson, was one not at all suitable for it; for although it must be very uncomfortable to use the throat instead of the anus for the evacuation of the fœces, he believed that the formation of an artificial anus would be a still greater evil. Other cases would, however, occasionally occur, in which it would be difficult to decide on the propriety of operating, without a due regard to all the attendant circumstances.

THE SYRIAN MEDICAL AID INSTITUTION.

Towards the close of the year 1841, a few gentlemen met for the purpose of considering what could be done to heal the wounds of Syria, which England had been instrumental in inflicting during the war then recently brought to a close. They came to the following resolutions:—

1st—That it is desirable on a consideration of the present condition of Syria, to establish a Society for the purpose of furnishing Medical and Surgical aid to the inhabitants of that country.

2nd—That it is proposed to attain this object by sending out one or more medical gentlemen of high professional character and acknowledged piety to Beyrout, or such other place in Syria as may be found expedient

It was especially kept in view that the chief motive of this undertaking was the hope that it would greatly tend to remove prejudice, and open the minds of the people to examine that religion which prompts to such efforts for their advantage.

For the purpose of carrying out these resolutions, the Syrian Medical Aid Association was formed. The liberal support of several distinguished individuals, whose names may be seen in the list of patrons and subscribers, led the committee to think that they were justified in making the experiment of sending out one medical agent, and Beyrout was selected as the place in which his labours should commence. Dr. Kerns, who received the appointment, was consequently sent accompanied by his wife, to that part, the Government, through the kind influence of Admiral Sir Robert Stopford, defraying the principal part of the expenses of the passage.

During the two years in which by agreement his services were engaged, Dr. Kerns justified the strong testimonials which had secured his election to the post. The prejudices of all classes in Syria gave way to the attractions of his kind and skilful treatment. Upwards of 4,000 cases were admitted at his dispensary in a single year, and several important medical operations were performed by him. A classified enumeration of the cases, and many interesting medical details were contained in the doctor's reports to the committee, some of which have been published in the professional journals at the time.*

As the close of the doctor's engagement drew near, the desire to devote himself more especially to the Jewish population of Syria, induced him to prepare himself for taking orders in the English church, of which he was a member, instead of renewing his engagement with the Association, although, as must be observed, in justice to all parties, that no diminution had taken place in his cordial attachment to the Association, or in the amount and success of his professional labours.

About the same time the valuable information and advice which the committee received from different quarters, made it evident that Damascus offered a field for labour, preferable to that of Beyrout, and Dr. James B. Thompson, one of the physicians of the Royal General Dispensary, and who was elected from more than 40 candidates, accordingly proceeded to that ancient city, accompanied by Antonius G. Ammung, a Syrian, who unites to a valuable amount of medical knowledge acquired in London, during three years study at King's College, the perfect mastery of the English, French, and Italian, as well as of his native language. The very great increase in the extent of labour, not only as respects the number of patients, but also as to the mode of usefulness consequent in his change of locality, has led to the most gratifying as well as surprising results, but which, it is proper to state, are wholly attributable to Dr. Thompson's zeal in the cause which he has undertaken, his long experience, high character, and sound judgment.

In addition to the dispensary, in which upwards of 5,000 cases have been relieved, in the short space of little more than seven months, a small hospital has been opened at the suggestion, and very much at the expense of, Dr. Thompson, who has generously devoted his own house and resources to this benevolent object.

The following are some of the particulars contained in the doctor's communications.

"We have all sorts visiting us, and some of the chief Moslem families, the true descendants of the Prophet; we even have gone so far as to get them to look at dried preparations and anatomical plates, which no person knowing their prejudices on these matters a few years ago, could suppose we should have brought about such a change, and cause them to feel and express an interest in these inquiries." * * * *

"I still continue to visit the two Segyier Asylums, and they are in a truly deplorable state. I have endeavoured to interest some persons on their behalf, and have latterly sent them some mutton, and money to buy some bread, and make a soup of the meat thus supplied; but I cannot do much myself if not aided by others."

"I have been latterly called upon to attend some females in their accouchement, and I am now making such arrangements as will secure a female attendant in each of the three quarters of the city, namely, the Christian, Jew, and Mahomedan districts, and select one of their own persuasion in each, who will receive proper instructions from us, and who shall be sent for when any female is taken ill in the district, and who will report to us forthwith, when the person will be visited and prescribed for, and further directions given to the nurse to tender to her till out of all danger. I propose to place these women under pay, and at a small weekly allowance, promising them a small gratuity at the end of the year, providing they attend to my instructions and prove useful auxiliaries to me in this department of my professional duties. I am sanguine, that by such means as these, we can soon break through the prejudices of the people, and convince them of the advantage of professional aid in these cases, and shall be instrumental in saving some hundreds of lives in the year, for in this city there is a great mortality in this very anxious period of female life. We have already saved a few lives from a premature grave by preventing the injudicious interference of female practitioners, and hope that we have convinced many of the older females of the superiority of British medical knowledge in this department." * * * *

"I shall be always most happy to receive any instructions from the committee, and shall pay strict attention to the proper and judicious distribution of any money which may be placed in my hands for the purposes herein detailed. Were the benevolently disposed people of England to witness half what I see in my daily visits, I am sure we should not lack funds sufficient to enable me to render more substantial relief to the poor than I can at present attempt or expect to do. I am now occasionally engaged in giving medical instructions to some of the native doctors."

"We witnessed the departure of the pilgrims

* See the published transactions and reports of the Association; the *London Medical Gazette* and the *Lancet*, of the 17th of March, 1843, the London *Medical Times* of January and 27th March, 1844; the *Medical Gazette*, and *Lancet*, for the 2nd of March, 1844.

for Mecca, amongst whom were many Persians. We were not in the least molested, though other persons in French costume were pelted with stones. We are well known, and would have protection from all parties and sects, even amongst the Bedouins, many of whom visit us from the remotest parts of the desert of Arabia. The Rev. Mr. Brookman who is here at present, is a medical student preparing himself to pick up Arabic, and a little medical knowledge to act as doctor in the interior of the country, which he is about to visit partly on a geographical tour and on general scientific pursuits. We are affording him all the aid and time in our power. I hope to dispatch him charged with a useful stock of knowledge to himself and his fellow-creatures, in the deserts through which he is to pass." * *

"Since my last letter I have had the honour of prescribing for the Queen Dowager of Persia, a very old lady, and I could see the tongue and feel the pulse of my royal patient, so closely and scrupulously was her Majesty veiled from my view; and still more strange, this privilege was only allowed me through her bed-room door-way, she sitting, or rather in the semi-erect position, attended by her waiting maid, or the lady of the bed-chamber. However, under these many disadvantages, I am happy to say my royal patient is now better. The ladies in the Hareems latterly unveiled themselves to me, and ask me sometimes to sit down." * * * *

"I am now the medical adviser of the Kahia Bey, the governor of the city, and he is so pleased with the great improvement in his own person since I have attended him, that he has honoured me with a visit, and brought all his *suite*, about twenty-five in number. They were all astounded at our electrical machine, a shock from which he experienced."

"Since then the Kahia has so far recovered, and is so grateful for the restoration to health, being a sufferer for many years, that he has sent me as a present a young Arab horse. In writing to Dr. Hodgkin I have alluded to this, and said that I proposed to have this horse's price appropriated, with any other moneys which I may receive in the meantime, to any purpose that both societies may suggest." * * *

Will the public allow the Syrian Medical Aid Association to be compelled suddenly to suspend its labours in the midst of more than anticipated success, and recall Dr. Thompson at the time when he has vanquished the greatest difficulties, because the comparatively small sum required to carry on the work cannot be raised amongst the British friends to Syria, a land to which we owe so much, and with which so many sacred associations are connected?

The annual expense at Damascus may be calculated at from four to five hundred pounds.

Unhappily, the donations and subscriptions which encouraged and maintained the first efforts, when the result was doubtful, have fallen off when success was secure, and at this moment the balance at the banker's is almost exhausted.

We shall be able, very shortly, to publish some interesting reports from Dr. Thompson. They are already in the hands of Dr. Hodgkin.

To the Editor of the Medical Times.

Gentlemen,—In accordance with a resolution carried at a meeting of the Herefordshire Medical Association, I have the honor to request, that you will insert in your able periodical the accompanying memorial, with its signatures, and the protest, at your earliest convenience.

I remain, Gentlemen, your obedt. servant,
HENRY G. BULL,
Hon. Sec. to the Herefordshire Association.

Hereford, April 5, 1845.

TO THE RT. HON. SIR JAMES GRAHAM, BART., HER MAJESTY'S SECRETARY OF STATE FOR THE HOME DEPARTMENT.

The Memorial of the Surgeons of the City and County of Hereford,

SHEWETH,

That your Memorialists, Members of the Royal College of Surgeons of England, resident in the City and County of Hereford, in compliance with the Oath they have recently taken, on being admitted Members of the College, to maintain its dignity and welfare to the utmost of their power, feel it to be an imperative duty respectfully to call your attention to the injustice displayed in the mode of carrying out the Charter recently granted to the Royal College.

Your Memorialists cannot but feel, that the Council of the Royal College of Surgeons of England has broken faith with the general body of the Members, by the principle of election to the newly created grade of the Fellowship, which it has seen fit to pursue. Full power was given to the Council by the new Charter to carry out this principle in a way which would not have interfered with the existing rights and privileges; but it has not done so. And further, your Memorialists consider the course it has adopted is most injurious and degrading to the overwhelming majority of its Members, and utterly at variance with those principles of honour and justice, which should distinguish a Royal College.

Your Memorialists fully recognize the right of merit to the distinction of the Fellowship; but this principle of Election can only be justly carried out to a very limited extent; and when it is thought necessary to go beyond this, they are of opinion, that the only just mode is then to make "length of standing in the Profession" the means of admission for all present Members to the Fellowship, (at once, if they have attained the requisite period, or as they respectively do so,) since it is the only plan which, from its not being retrospective, would prove satisfactory to the Members in general, and regain for the Council that perfect confidence which has been so much shaken by a departure from it in the late proceedings.

For these reasons, your Memorialists would humbly, but earnestly suggest, for your consideration, the propriety of advising her Majesty to grant a new Charter to the Royal College of Surgeons of England, or to sanction such a modification of the present Charter, as will effectually remove the injustice which has been thus cast upon the majority of the Members of the College; or, in the event of neither of these plans being deemed admissible, your Memorialists would also respectfully suggest for your consideration the propriety of advising her Majesty to grant a separate Charter of Incorporation for the General Practitioners, as a measure then essentially necessary, in their opinion, for the maintenance of the welfare and prosperity of this most important class of the Profession.

A Protest, couched in a similar spirit, directed to the "Insane" Council, and signed by the same gentlemen, has been also prepared.

OBITUARY.—1. Dr. Ribes, on the 21st February, of an inflammatory affection of the lungs. He was a military surgeon of high distinction, *sharing in most of the French* military campaigns between 1792 and 1815. His principal work was his "Memoirs and Observations on Military Physiology and Surgery." His last appointment was as head of the Medical Staff of "the Invalides." In his fatal illness, it is a singular fact, that this amiable and universally revered surgeon, spurned, like the celebrated Double, the aid of that science to which he had so much contributed. This medical scepticism of eminent medical men is a subject well worthy a chapter in some new Curiosities of Literature. 2. At Paris, Dr. Ollivier (D'Angers) on the 13th ult., in his 49th year. His principal work is "On Diseases of the Spinal Cord." 3. Dr. Rumsey, at Henley-on-Thames, on 3rd February. He was a very able surgeon, and was the author of many valuable papers in the different journals—one "On Fever caused by Depletion," anticipating on that subject many of the views of Dr. M. Hall and Mr. Travers. 4. At Dublin, on 28th February, Montgomery Ferguson, M.D. 5. At Brighton, on 30th March, Dr. Theodore Gordon, the eminent Deputy-Inspector-General of Hospitals. 6. At Dublin, on 31st March, Dr. Thomas Orpen, aged 69.

ULTIMATUM OF THE ROYAL COLLEGE OF SURGEONS IN ENGLAND.—[Our leading article last week had reference to the long letter published by the College of Surgeons, the following abstract of which has appeared in the *Morning Chronicle*. It may be added that the *Times* has given the document a condemnation in that forcible language which that journal knows so well how to employ.] On the 20th ultimo the National Association of General Practitioners, in a desire to accommodate the differences between its constituents and the College, addressed these three interrogatories to the letter:—"1. Is the Council of the College prepared to reconsider their charter, and to place those members who were in practice before it was granted on a level with the fellows? 2. Is the Council of the College disposed to admit to its board a fair representation of the members of the college in general practice? 3. Would the Council of the College be willing to co operate with the National Association in the formation of a Court of Examiners in medicine, surgery, and midwifery." On the 3rd of this month a reply was returned, directly refusing, in very supercilious terms, the Council's assent to any of the concessions suggested. The reply was turned into an occasion for a very elaborate defence of their recent conduct. They insist that their election of fellows was governed, not by private patronage, but wholly for the public good; endeavour to show that the science of surgery would be much impaired if surgeons in general practice were admitted to the high places of their college. The following passages are worth being given entire:—"The Council's description of their own Members."—"It has been also proposed, that as vacancies occurred, the places might be supplied, until all the members admitted before September, 1813, had been placed in succession on the list of fellows. But it behoves those who contend for any mode of forming a list upon the simple principle of seniority without selection, and still more those who urge the indiscriminate admission of all members to the fellowship, to weigh well the insurmountable objections to their scheme. Would they include those who have violated the laws of their country? Would they include professional paupers, and persons of notoriously bad character? Would they include the puffers and venders of nostrums and secret remedies, and the writers of indecent advertisements? Would they include surgeon's assistants, or those who have connected themselves in business with druggists and chemists? Would they include the retail shopkeepers who expose for sale cattle drugs and perfumery? Would they, finally, include or exclude all those who keep open shops and who, though ill sustaining a professional character, are yet not chargeable with any moral disqualification? In short, would the National Association, in conformity with their views, advise admitting all such as members of the proposed College of general practitioners, without discrimination or selection, merely because they are members of the College of Surgeons, or licentiates of the Apothecaries' Company?"—Comfort for Members displaced by the late Charter.—"The council, therefore, under a sense of justice to their future members, who will possess the same qualification as the present members, and under the obligation, which the institution of the novel honorary degree imposed, necessarily sought other evidence of distinguished surgical attainments than the ordinary diploma, which attests only the amount of proficiency required of all. And those who feel disappointment would do well to bear in mind that they have been deprived of no privileges nor corporate rights, which they acquired, or hoped to possess, in becoming members of the college. They will recollect that in applying for their diploma they were not compelled to do so by any legal enactment, as they would have had an equal right to practice surgery without it, and they will probably admit that their sole inducement was that of obtaining in the diploma a testimonial to which the names of some of the principal hospital surgeons and teachers were appended. And let them not forget that one of the first acts of the college was to make a by-law, which was sanctioned by the proper authorities, excluding practitioners in pharmacy and midwifery from the governing body of the college, that they obtained their diploma under this known condition, and that they actually signed this and other by-laws, and swore to observe them." The document is, in short, a defiance to the general practitioners to do their worst; the majority of the Council maintaining in their teeth, and in a fashion somewhat insulting, the *status quo*.

No. 299 **SUMMARY.** April 26.

THE STRUCTURE AND FUNCTIONS OF THE BRAIN WITH NEW VIEWS ON THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine.

Formerly Physician to the Bicetre and Salpetriere Asylums. Author of the "Traite Medico Philosophique sur l'Alienation mentale "Medicine Clinique," "Nosographie Philosophique," &c., &c. Translated with Notes illustrative of some important doctrines in Physiology, Phrenology and Moral Education,

By Dr. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c.

(Continued from page 27.)

STUPOR, ACUTE DEMENCY, ŒDEMA OF THE BRAIN, STUPIDITY OF GEORGET, STUPOR OF ORFILA.

Amongst the enfeeblements of the intellect that form a well characterized malady, one of the most curious and most novel in its study is, that intellectual and moral annihilation, more or less prolonged, which Esquirol was the first to describe under the name of *acute demency*. He had observed that certain maniacs are often suddenly struck with almost complete abolition of all their faculties, a particular demency differing from common demency, inasmuch as it almost always attacks a young subject, and quickly terminates in cure. Most likely he bestowed the name of *acute demency* on this affection as much on account of the rapidity of its attack as of the promptness of its cure, notwithstanding the gravity of the symptoms.

Struck with the frequency of this affection, Georget has thought proper to consider it as a new kind of mental alienation, designating it by the term stupidity : according to his definition it is an accidental absence of thought, whether it be that the patient has no ideas, or that he is unable to express any. He narrates the two following cases to give an idea of this species of insanity. Adele F. aged 36, was admitted into the Salpetriere, for the fifth time in ten years, with the following symptoms :—general insensibility ; no answers ; complete immobility ; look of stupidity ; it is necessary to get her in and out of bed, and to attend to her natural wants ; a seton is inserted into the nucha without exciting any sign of sensibility. This state continues for three months, and then ceases suddenly after abundant ptyalism and head-ache ; the intellect resuming its usual activity. Another young woman was admitted also into the Salpetriere in consequence of a fright : there was general paleness ; stupid look ; no answers ; profound indifference ; involuntary evacuations ; after a little time some amendment occurred, and she began to be able to give some account of what she had felt ; she could hear well, but she could not unclose her teeth. These characters form the foundation of the distinction and denomination proposed by Georget.

Another judicious observer, M. Etoc Demazy has entered into deeper researches on the subject, which form the subject of his thesis. He was the first to establish some of the points of connexion between this intellectual annihilation and the serous and œdematous infiltration of the brain itself, and mentions to this effect several cases, of which I shall make use hereafter ; but while thus advancing successfully, he stops from prudence and returns to Georget's symptomatic definition.

This intellectual annihilation which may, after Orfila, be justly called the acute stupor of the insane, is the result of serous infiltration, of a particular kind of œdema affecting the convolutions of the brain, and in these cases, the mobility, sensibility, and the senses present derangements no less singular than those of the intellect. It should be added that this malady is totally different from those serous effusions described under the names of acute and chronic hydrocephalus in infants and adults ; these effusions which usually occur in the interior of the ventricles disturbing the cerebral functions by the gradual extension produced by them from the interior of the brain to the exterior. In cerebral œdema the phenomena are reversed; the fluid secreted on the surface of the brain insinuates itself into the anfractuosities, into the brainy tissue, until by at last compressing the whole periphery of the organ, it gives rise necessarily to lesions of different functions, that have no analogy with the effects of common hydrocephalus.

A subject so interesting ought to be studied through the aid of well-observed cases, and inductions carefully made. For this purpose we shall first relate some clinical observations, pointing out in each the coincidence of the œdema with the profound disturbance of the cerebral functions ; afterwards we shall speak in detail of the symptoms, progress, treatment, general anatomy of this œdema, and of the physiological inductions that may be drawn from them.

Case i.—Anna B. born at Cologne, was married in 1812 at the age of 32 to a French soldier. Having been separated from her husband six years, and not having had any news of him during all that time, she imagined that she would be able to find him in Paris, and for this purpose repaired to that capital in 1818, intending to obtain a livelihood as a servant, although she did not understand a word of French. During twelve months her search was fruitless, and it was only with difficulty she could get a situation. From grief and distress, she was soon cast into a state of deep melancholy, and was sent to the Salpetriere on the 4th June 1819.

At this time she was in a state of complete taciturnity, and would retire into the corners of the dormitory to hide her face with her hands : it was necessary to use force to make her take food. This state of melancholy lasted seven months. She then began to appear less wild ; to speak freely. She asked for work and it was supplied ; her intellect appeared to recover from a lethargy, and for three years she made herself useful in the hospital.

In 1823, her husband, who had heard of her illness, and the place of her retreat came to see, and to reclaim her. She recognized him without emotion, treated him as one who was indifferent to her, and preferred remaining in the establishment where she was employed as a servant.

In 1824, it was remarked that her memory failed her occasionally, that her fits of absence were frequent ; the enfeeblement of her faculties became soon so great, that she was sent back amongst the patients. In the course of a month the stupor was complete. She was totally incapable of helping herself in any way ; when dressed, she remained in the same position in which she was placed, almost motionless.

Her constitution began to be seriously affected ; the body wasted, and there was slight continued fever. She never spoke, her eyes remained always open and vacant, she could still move her arms, but the limbs were no longer able to support the body.

One circumstance struck me forcibly ; one of her companions in attempting to give her a pinch of snuff, let some of it fall on her eye ; I was greatly surprized at finding that so powerful an irritant produced no sensation on the surface of the eyes, and this set me upon exploring the other senses, and regions of the body ; sulphuric ether did not appear to produce any effect on the tongue, nor on the sense of smell ; a bit of cotton was burned on her thigh, without her perceiving it ; on the other hand, the sensibility was unimpaired in the skin of the arms, as was evident from the signs of pain on pinching. In regard to the intelligence, there was no perception, the muteness was complete with all the symptoms of profound stupor.

A gangrenous eschar formed on the sacrum, and death, which followed on the 28th November 1824 from marasmus and prostration, took place six months after her relapse, and two months after I had observed the symptoms of paralysis of the senses, and of the lower extremities.

Autopsy.—Exterior ; general marasmus, denudation of the sacrum, slight œdema of the lower extremities.

Head.—The skull is thin, transparent and strongly adherent to the dura mater, which appears healthy externally ; after incising it and carefully removing it, I was struck with the gelatinous appearance of the surface of the brain. The arachnoid, healthy throughout the lateral and posterior region was so much distended by the serum beneath it, that the two hemispheres looked as if covered with a layer of something resembling apple jelly. This appearance is removed by incising the membrane and allowing the serum to escape ; four ounces of this fluid of a reddish colour, the accumulation of which seemed greatest in the parietal region, were collected. The entire frontal region was the seat of a different alteration ; here the arachnoid was thickened, adhered to the brain and converted into a solid albuminous exudation, about a line thick. The arachnoid at the base of the brain was healthy, and free from serum.

Pia Mater.—The tissue of the pia mater contains albuminous granulations, and appears at certain points infiltrated with a yellowish liquid, and throughout this membrane is thickened and reddish.

Brain. Grey Substance.—At the upper part of the hemispheres, the grey substance has lost colour, is soft and almost white ; it seems to be penetrated throughout by serum with which it had been in contact ; on incising and pressing the convolutions, small drops ooze out, not reddish as they are usually, but limpid and transparent.

Throughout the base of the brain, the grey sub-

stance is very different; it is blackish, and deeply injected; at every incision, blackish drops ooze out, and its adhesion to the arachnoid is so strong, that on trying to separate them, the brain peels off with it.

White Substance.—This substance seems healthy throughout the entire upper part of the brain, and it is only at the basis that it appears to participate in the alteration already observed in the grey substance of that region; it has the livid colour of ecchymosis, and there are yellowish rounded softenings, of the size of a nut in several places.

It cannot be mistaken that the whole base of the brain has been the seat of a morbid concentration of blood, whilst on the other hand, all the upper part was bathed in a serous fluid, through which the grey substance was deprived of its colour.

Peduncles.—On examining attentively the crura cerebri, their inferior surface presents the same alteration as that observed throughout the base of the brain; they are softened and blackish, but the alteration is not deep, and the rest of their substance possesses the ordinary consistence.

Ventricles.—The lateral ventricles greatly distended, contain about three ounces of a turbid reddish serum, like that found at the surface of the brain; the middle ventricle contains also about two drachms of the same fluid.

The walls of these ventricles are not smooth as in their natural state, but studded with irregular patches of false membranes a line thick, granulated and yellowish but soft, and reducible to a pap on the slightest pressure.

Both the corpora striata present a very remarkable alteration; without having lost their natural shape, they are perforated by several small holes which contain a sort of jelly of a brownish hue, and offensive smell; the sides of these cavities are soft, irregular and rugous.

The annular protuberance is disorganized and softened at its inferior surface, and partakes of the general alteration of the base of the brain; but the softening is only superficial.

The vertebral canal being opened throughout its entire length, the dura mater appears distended; a large quantity of a fluid similar to that found in the ventricles issues from it. The consistence and colour of the spinal marrow seem natural externally, but its internal grey substance is entirely deprived of colour.

Excepting a vivid redness of one of the small intestines, the other viscera were healthy.

Reflexions.—Notwithstanding the multiplicity of the alterations observed in this case, it is possible by comparing them with the symptoms and progress of the disease, to class them under two heads; on the one hand we find an affection of the periphery of the brain and of its dependances, which are bathed in a large quantity of serum; and on the other, the entire base of the brain as well as the inferior surface of the mesocephalon presents evident traces of sanguineous congestion and of inflammatory disturbance.

Let us now see the relation that these lesions bear to the progress and symptoms. Four years before this patient was attacked with profound melancholy, which yielded after lasting seven months; after this, fresh symptoms announce the gradual decline of the faculties, and at the end of a month, the stupor and immobility were complete. This new malady was nothing more than a more serious repetition of the melancholy by which she had been attacked three years before. After seven months of stupidity, the insensibility became profound and general, all the senses seem to be paralysed.

In endeavouring to explain the symptoms by the alterations found in the encephalon, I think I am warranted by analogy in ascribing the first attack of melancholy and taciturnity to a serous effusion, similar to that found in the dead body after the relapse.

In the first attack the effusion is absorbed at the end of seven months, and leaves its traces in the meninges in the form of an albuminous exudation in the frontal region, and of patches in the ventricles. Three years later, slight disturbance of the intellect announces the occurrence of another serous congestion, which attains to such a height in the course of a month, as to abolish all the intellectual functions, by compressing the brain and then infiltrating into the convolutions, the ventricles, and even into the vertebral canal.

From that moment, the intellectual and mobile powers are entirely abolished: the senses too are profoundly paralysed, but towards the termination of the disease, symptoms of still greater prostration and febrile marasmus shew that in addition to the affection from which the stupor and general insensibility arose, another malady still more serious has supervened. I thus explain the inflammation of the whole base of the brain, and of a part of the nervous centres, as shewn in the red injection and especially by the partial softening of all these parts; and moreover that the latter affection could not shew itself by very marked symptoms, on account of the pre-existing general paralysis produced by the compression of the brain.

This is the only case that I have met in which the cerebral fluid was effused into the encephalic cavity in such large quantity. This general immersion must necessarily have given rise to symptoms more general and more profound than those which I shall have to describe in the following cases, in which accumulation of serum has been confined to the surface of the brain, or to the substance of the superior convolutions. Accordingly in these cases we shall only have to notice the blunting of the intellect and of the sensibility. But before I proceed to these, I shall detail another case in some respects analogous.

PATHOLOGY OF EXPECTORATION.

By S. Wright, M.D., Edin., F.S.A.,
Physician to the Birmingham General Dispensary; formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c, &c.

(Continued from page 35)

Dr. Stokes submits the following classification of sputa arising from irritation of the bronchial mucous membrane.

1st.—Transparent mucous secretions.
2nd.—Opaque mucous, or albuminous secretions.
 a. Amorphous.
 b. Moulded to the form of the tubes.
3rd.—Muco-puriform secretions.
4th.—Puriform secretions.
5th.—Serous secretions.(1)

Dr. Williams reduces the varieties of sputa to this number;

1.—*Mucous*, more or less transparent and viscid.
2.—*Albuminous*, opaque without viscidity.
3.—*Watery*, thin and transparent.
4.—*Compound*, composed of combinations of the preceding kinds.(2)

It has occurred to me, as the result of much careful enquiry and thought, that no classification of sputa can be of any real avail in diagnosis, unless it shall embrace, with whatever comprehensiveness it may be requisite, all the varieties of expectorative matter which we know to accompany diseases and disorders of the respiratory organs. But whilst treating thus widely this important branch of medical science, we must be careful to avoid all unnecessary and fanciful minuteness—all ideal degrees and shades of distinction—all matters, indeed, which are not founded upon accurate pathology, or which do not pertinently bear upon medical practice. Such errors, however, are the less likely, in proportion as we patiently investigate, and impartially record, those practical truths which are only to be learnt by a faithful attendance upon the sick, or by a scrupulous examination of the dead.

The following are the varieties into which I have found it most convenient and practically useful to divide the matter of expectoration. This classification was made by me more than seven years ago, since which time I have been in the constant habit of availing myself of its guidance in the diagnosis and treatment of chest diseases, and of rendering it with what care and accuracy I have been capable of, suited to the service both of the pathologist and the practitioner. And after such a duration of trial I may perhaps be permitted to say, that I am now less disposed than I have ever been, to question its truthfulness or its use:

1.—Thin mucous sputum.
 a. Insipid.(3)
 b. Acrid.
2.—Thick mucous sputum.
 a. Transparent.
 b. Opaque.
3.—Muco-albuminous sputum.
4.—Muco-purulent sputum.
5.—Purulent sputum.
6.—Tuberculous sputum.
7.—Concrete and coagulated sputum.
8.—Gelatinous sputum.
9.—Serous sputum.
10.—Hydatid sputum.
11.—Bilious sputum.
12.—Bloody sputum.
13.—Melanotic sputum.
14.—Sweet sputum.
15.—Saline sputum.
16.—Calcareous sputum.
17.—Frothy sputum.
18.—Fœtid sputum.
19.—Coloured sputum.

Thin Mucous Sputum.—*a. insipid.*

The variety of expectorated matter which comes under this denomination, has long been regarded with interest both by the pathologist and the practitioner. Occurring as well in acute as in chronic affections of the respiratory organs, and affording most important indications, diagnostic and remedial, it especially merits our deliberate consideration and comment.

Appearance and qualities.—This mucous sputum, of the insipid variety, is sometimes scarcely distinguishable from water. At other times, it is more or less opaque and frothy, with a faint blue, green, brown, or red tinge.—It is usually insipid and inodorous; but, in some cases, it has a mawkish, sickly, or saline taste, and a musty or mucous smell. Its reaction upon test-paper is either neutral or very feebly alkaline. Its specific gravity is very variable: it will often exceed 1·0, and again will reach 1·008.—(Mucous sputum which is beyond this density, I class with the "thick" variety. The distinction is, of course, perfectly arbitrary, but I find it convenient for practical purposes.)

The density of this sputum is, of course, directly as the amount of animal and saline matter contained in it—at most, the proportion of these is very small. It never contains free albumen or pus. A minute quantity of chloride of sodium is generally present, but I have never been able to discover in it any of the earthy salts. In its purest state, it answers to reagents like a very dilute solution of nasal mucus. It may contain adventitious materials, as bile, blood, urate of soda, &c., according to the diatheses or diseases in which it prevails; but this impregnation is of very rare occurrence.

Pathognomonic relations—Thin mucous sputum is discharged in the various affections of the system—of the respiratory, and of other organs. It sometimes precedes an attack of influenza, and not unfrequently seems to prevent it. I have known it to occur suddenly, and without any warning, during the existence of influenza, and, for a time, to suspend every other unpleasant symptom. It is commonly met with in acute catarrhal affections (4.) In these cases, a sudden arrest of the expectoration, either spontaneously, or from exposure of the chest or feet to cold, from the violent action of hydragogue cathartics, or from sudden and severe diuresis, is frequently succeeded by pneumonia, terminating in serous engorgement; by pleurisy, pericarditis, peritonitis, or meningitis, attended with rapid effusion; or by sudden determination of blood to the head, with profound apoplectic symptoms.

(1.) On Diseases of the chest, pp. 59-60.

(2) Pathology and Diagnosis of the Diseases of the Chest, 4th edition, p. 59.

(3.) The term "insipid," as applied to this variety of sputum, is conventional, and only of relative signification.

(4) By the older authors, this form of expectoration (if accompanied with fever) was termed *catarrh*; if (without fever) it was called a *flux*.

It never accompanies acute bronchitis of a severe form; but in young subjects, particularly females, it is apt to occur as a sequela of this affect on. In very mild bronchitis, attacking debilitated or leucophlegmatic people, there is often a profuse secretion of thin mucous sputum; and in bronchial irritation, sympathetic with sub-acute gastritis, especially the erythmatic variety, it is ocnasionally observable (5). In some rare cases it is symptomatic of dyspepsia complicated with gastro-enteritis, the spasmodic and burning pains of which are generally relieved by the expectoration that occurs profusely, and almost without intermission, during the harassing and tickling cough which attends it. In these cases the discharge has a certain pathological analogy to water-brash (6).

In dropsical affections, both general and local it has been remarked; and cases of anasarca are said to have been cured by it. I have more than once known it to afford marked relief in such affections.

Disease, as well as disorder, of the uterine organs, is sometimes attended with sympathetic cough and copious expectoration of thin, transparent, insipid mucus. With some females it occurs during the menstrual period; with others it appears to be vicarious of the catamenial discharge; and with a third class, it will accompany the habitual nervous cough of amenorrhoa.

It is, very rarely, a symptom of pregnancy: the cough of gestation usually has no expectoration at all, or the matter expectorated is of a "thick mucous," or "muco-albuminous" nature.

The commencing slow deposite of tubercles not unusually excites sympathetic irritation in, and profuse mucous discharge from, the tracheal and brochial inner membrane. It was remarked by Cœlius Aurelianus that, "the irritation from tubercles often causes an expectoration of very thin mucus," which he denominated "limpid sputa." It is only in the early stages of phthisis that this form of expectoration exists alone. I have never once remarked it, during the period of maturation or softening of tubercles, or when there has been a cavity in the lungs (7.)

Of the retrocedent gout of adolescence and senility, this kind of expectoration is an occasional symptom. The exacerbations of gout are sometimes arrested or relieved by the discharge occurring profusely (8.)

A discharge of this mucous sputum sometimes accompanies general or local rheumatism (9) (especially affecting the muscles of the neck and chest), the milder forms of ague, measles, small pox, and other exanthemata. The sudden suppression of habitual discharges often gives rise to it (10). It is not an unfrequent attendant upon hypochondria and melancholy.

(5) It is not a common symptom in these affections—the cough of gastritis is usually dry.

(6.) LangstonParker mentions a striking case of chronic gastritis, upon which, cough with profuse expectoration supervened, as it were remedially. "In this case, several particulars are worthy of notice: all the symptoms with which this patient had been troubled, through a long period, were evidently dependant on a chronic state of inflammation of the mucous coat of the stomach. The symptoms which denoted this condition of the stomach were unusually rebellious. They were palliated and relieved sometimes for a week together; but again recurred with their primitive severity. At this period the catarrh, with expectoration, set in. When the latter was fully established, the disease in the stomach began to subside, and ultimately disappeared. The catarrhal affection appears to have acted as a revulsive upon the disease of the stomach, and thus to have cured it. Occasionally affections of the chest and stomach alternate in this manner; we observe one subsiding as the other is aggravated.".—"The stomach in its morbid states," (p. 21.3) Broussais relates a remarkable case of catarrhal and pneumonic symptoms arising sympathetically from acute gastritis, in which the lungs were found healthy after death.—"Histoire des Phlegmasies Chroniques tome," 2, p. 459; and another striking case, somewhat similar, at page 466.

(7) Richter says it may be either a cause or a consequence of tubercles in the lungs. He says "the discharge is to the lungs what leucorrhœa is to the uterus, or gonorrhœa to the urethra, arising from an irritation which is commonly either gastric or rheumatic, or perhaps syphilitic." He details a case which occurred after intermittent ever.—Medical and Surgical Observations from the German, 1793, ed. 1794, 8vo. p. 260, et-seq.

(8) Bordeu, in his researches on the pulse, speaks of a gouty subject, whose attacks were generally arrested by an abundant expectoration of mucus.

(9) Sauvages, in speaking of the "Rheuma epidemicum, anni 1743," says "juvenes tussi sicca, dolore artuum, ephemera, cephalalgia affecti, post quartam diem sputo supervenicnte sanabantur.—Nosol. Method. Amstel., 1768, tom. 1, p. 688.

(10) A case is related in the Annales de la Medecine Pratique de Montpellier 1804, tome 7, p. 125, in which distressing cough and profuse expectoration appeared on the suppression, by acetate of lead injections, of syphilitic blenorrhagia. The cough and expectoration were relieved by inducing a return of the urethral discharge.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES—MORBID AND HEALTHY,

By Dr. Knox, F.R.S.E., F.R.C.S.E.,
Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

LECTURE IV.

The evident importance of the skeleton of the head as containing, and in some measure portraying, the brain and some at least of the organs of sense, must, no doubt, be at once a reason and an excuse for the so frequent recurrence to its examination by anatomists and pschycologists. That the brain is the instrument of thought no man can doubt, any more than that man receives most of his knowledge through the organs of sense. But the skull-cap is unquestionably moulded on the brain, being, as it were, adapted to it by its internal surface; sympathising with it, no doubt, by this surface; whilst its external layer has quite different relations, sympathies, and connexions. These, however, are not by any means the sole difficulties which exist in the endeavour to form an estimate of the relation of the cranium and osseous face to the brain and intellect; the mesial parts of the base of the brain clearly represent the bodies of the cranial vertebræ, whilst crests are continually found on the external surface of the cranium, having a reference neither to brain nor muscular attachments.

Certain osseous cavities of the human skeleton disappear constantly, or are obliterated soon after the withdrawal of the organ usually found distending them; this happens to the alveoli or sockets for the teeth, and the cotyloid cavity of the haunch bone when the head of the femur has been forced from it and not replaced. Even the thorax will diminish to an incredible extent, and permanently, should the lung be so diseased as to contract greatly on itself; I do not know, however that this happens with the cranium. In those cases, where a large portion of one of the hemispheres of the brain has been destroyed by disease, effused fluids have been found to take the place of the diminished brain, and so the cranium has remained of its original dimensions. There is still another difficulty. In the line of the cranial sutures there exist irregularly-shaped supernumerary bones, whose true nature it is impossible to determine, and whose physiological history cannot be included in any physiological principles, transcendental or otherwise.

II.—The division of mankind into *nations* is a human contrivance; nature acknowledges only *races*; of the existence of this great fact—for such it is—I first became convinced in Flanders in 1815. The principle which I have ever since entertained was fully proved true by what I saw in Southern Africa. Races of men totally distinct from each other have existed since the earliest period of recorded history; the negro face and form may be seen on the ancient tombs of Egypt as distinctly characteristic as at the present moment. There exists no evidence that a race of men has ever altered in shape or color, or, indeed, in any way from its primitive confirmation; the modern Copt does not differ from the ancient Egyptian; if he did so he could not have been descended from him.

The examination of the skeleton of the human head thus presents avowedly great difficulties; hence the conflicting opinions of anatomists of acknowledged eminence; instead of solving any problems, they have not unfrequently merely added others requiring to be solved. To this day it is impossible even to conjecture on what grounds Herodotus called the Egyptians a *black* race, for we know that they were not so; the exact counterpart of the head of the young Memnon in the British Museum may be daily seen in any Jewish synagogue.

Aware of the difficulty in arriving at any just conclusion, it occurred to me that a careful examination of the very excellent collection of crania at present in the rooms of the Phrenological Society might contribute something to the history of races, and with this view I beg leave to present the following remarks to the consideration of anatomists.

The collection consists of about two hundred and sixty crania and plaster casts. Of the crania many could not be examined, being as it were mummies and covered with dried integuments.

In this examination I was assisted by Mr. Desaret, whose familiarity with this line of enquiry aided me greatly. We first attempted a very great number of measurements, but failed in drawing from these any sound conclusions. Every cranium was measured in a great variety of ways, and we preserve the tables, but think them at present unworthy the attention of scientific men. This question of the inportance of measurements is most assuredly an extremely difficult one, and before commencing the enquiry I was sanguine as to the result; notwithstanding the perseverance of at least ten days' labour it failed, as I think, altogether.

The following are the only tables I shall venture, at the present moment, to offer to the public, and I should regret much to think, that any implicit confidence was reposed in them by any one; still they are curious, however imperfect.

Length of Base of Cranium, including Face.

Race.	Number of Crania.	Longest.	Shortest.	Average

Parsee	2	7	6 14th	6 15-16ths
Albanian	1			6 10th

It may first be observed, that in the drawing up of these tables, the race, or nation, or tribe, to which the person belonged, is stated in the first column; the authenticity of this rests, of course, on the Society, or rather on the person who transmitted the crania to the Society. All the crania are carefully marked, generally with the name of the race or nation, also with that of the donor, and not unfrequently some other circumstance is stated, having a reference to the cranium. The authenticity, then, of these markings rests with the person or persons who made them, whether donors or others. The second column contains the number of crania examined; the third gives the highest or longest measurement as the case may be; the fourth, the shortest or lowest, and the fifth gives the average of all examined. The first class of measurements we attempted, I mean Mr. Desaret and myself, regarded the entire length of the osseous head from the external occipital protuberance to the edge of the incisor teeth. Neither of us attached any great importance to this measurement; it included too much or too little; and it mingled up the longitudinal capacity of the cranium with a portion only of the face: of the cranium, containing the cerebral and cerebellar masses, and of the face, exclusive of the lower jaw, and consequently the ceiling and extent of the facial cavity. The results are now before the public in table 1, showing that the law of extent of the parts of the skeleton specified is unconnected with race, or nation, or tribes, or presumed amount of intelligence, of education, or of civilization. The longest heads measured in this way were those of—

	Inches.
The New Zealander	8 2-16
The Ashantee	8 2-16
The Esquimaux	8 2-10
The natives of Van Diemen's Land	8 2-16
The shortest was :—	
The Hindoo	7 1-16
The Phillippine	7
The Albanian	6 10-16

The difference between the longest and the shortest was exactly one inch and a quarter. The Scotch head is large, or rather long, measured in this way; the Irish is comparatively short. Attaching little or no importance to these results, as well from the fewness of the specimens (116 crania), more especially of most of the races, as from the mingling up of two distinct anatomical and physiological elements (cranium and face), they may still serve as a nucleus for future enquiry. My first impression on looking over these tabular results was, that the decidedly greater bulk and projecting jaw of the dark races, a character of universal prevalence with them, had compensated for the presumed shortness of their *crania proper*, bringing them up, as it were, artificially, to the character of the *long-headed* races of men; we shall afterwards see how far this idea is supported by the other measurements. In this enquiry, more perhaps than in any other, the enquirer starts loaded with the prejudices and the learned rubbish of ages; from Aristotle and Hippocrates to Gall and Spurzheim; it seems almost impossible to clear the mind from them; from ideas which appear like truths, or self-evident propositions, namely, that the cranium must to a certain extent, portray the brain contained within it, and be an index of its form, bulk, and character; that the brain being evidently the organ or instrument of thought or intellectual operation, must be an index of the power and capacity of its own functions; that history shows the dark races to have been always inferior to the fair; that they ought and must have smaller brains, and in consequence smaller crania; these and similar prejudices so beset the path of inquiry as to render it by far the most difficult of any I am acquainted with. No two persons attach the same meaning to the same terms; the words *genius, ability, talents*, are used by most writers as nearly synonymous; according to some, Burns' genius was great and innate; others will have it to be accidental, and dependant more on his hasty temper and violent disposition, or as they term it, his temperament; but one thing is certain, that whilst he guaged beer barrels at a wage inferior to that of most tradesmen, somebody whose name I do not recollect, was Poet Laureat; his, I mean Burns', cranium, was not of any extraordinary capacity; he wanted genius to be a statesman, or even a town councillor, for which offices, moreover, his absurd notions of honesty, truth, and fair dealing, wholly disqualified him. Let us return to the measurements.

Table 2nd gives the results of a measurement to which, before making it, I was disposed to attach a good deal of importance; it gives the actual height of the cranium measured from ear to ear (*meatus auditorius externus*) over the vertex, with a tape; the columns are arranged as in the preceding table.

Ear to ear over the vertex.

Tape measurement.

Race.	No.	Longest.	Shortest.	Average
Swiss	4	14	13	13 10th
New Zealander	1			13 4th
Barbadian	2	13 8th	12 12th	13 2nd
Araucanian	1			13

Peruvian	7	13	11 6th	12 3rd
Hindoo	52	13 4th	11 4th	12 2nd
Chilian	2	12 4th	12 3rd	12 2nd
Albanian	1			12 2nd
Mozembique				12 2nd
Negress	1			12
Flat-Head Indian	1			12
Madagascar	1			12
Parsee	1			11 15th
Black-Foot Indian	2	12	11 12th	11 14th
Caffre				11 14th
Vera Cruz	2	12 4th	11 1th	11 12th
Circassian.				11 12th
New Hollander	5	12 4th	11 4th	11 11th
Bosjeman	2	11 8th	11	11 4th

A glance at the averages will show you extraordinary results if we could but depend on them; the whole races of men here enumerated may be classed first under those whose measurements run up to the figure 13.

	Inches.
Swiss	13 10-16
New Zealander	13 4th
Araucanian	13 2nd
Phillippine	13

2° Those crania which ascend in the scale to 12.

Javanese	12 14th
German	12 13th
Chinese	12 10th
Of Van Diemen's Land	12 8th
Scotch	12 7th
Seminole	12 7th

Even the Madagascar and the Negress rose to 12 inches.

3° Those who show the figures of 11 inches and upwards —

Parsee	11 15-16
Blackfoot Indian	11 12th
New Hollander	11 11th
Bosjeman	11 4th

These results require no comment; but still it excites my unmingled surprise that the world produces so few like Byron, seeing that there are millions of dark men who excel him in all the dimensions of the cranium, and especially in that quality of *height*, a quality presumed to be that on which the poetic genius more immediately depends. After all, was Byron a poet and a man of genius; a poetaster in a celebrated Northern magazine asserted in more critiques than one, that he was neither, and compared in an elaborate *critique* the Mazeppa of Byron to the no less immortal poem of John Gilpin; but Byron was alive at the period, and the poetaster wrote only for the day.

All comment on this table is unnecessary.

Absolute bulk of brain must, say some, always be, *cæteris paribus*, the measure of ability, and power, and genius, and of the strength of the intellectual character. Against this dogma, there lies the notorious fact that the activity of many glandular and secreting organs cannot be measured by their bulk or size; but as regards the brain they offer you the heads of Cromwell and Cuvier; odd conjunction, and of innumerable other "large headed men." The largest headed men of my own acquaintance have been town councillors and jobbers about public offices; men of energy no doubt; calculating men; unscrupulous; dishonest, but destitute of genius or elevated thoughts; a small-headed, vain man is usually selected as chairman. This class must, I think, also include all statesmen who are found competent to hold office, the least inkling of honesty of purpose being a total and absolute disqualification; those also who strive at and attain to offices of trust and profit by writing cleverly, singing a good song, &c.; and those who compile works ingeniously by a mosaic carpentering, skilfully adjusting the various parts; excluding the names of authors *not in office*; including the names of all friends, the amount of friendship being measured by the official status of the person addressed. But that absolute bulk of head is in any shape connected with high intellectual operation (unless the above mean arts be esteemed proofs of such) may, I think, be refuted by the following table, scanty though the materials be:—

Circumference above the Glabella.

Circassian, 1		..	.. 18 12th

The measurement given in this table is simply the circumference of the cranium, a little above the glabelle in front, and over the external occipital protuberance; it is, of course, the largest measurement of the cranium proper, and may be supposed connected with the bulk of that portion of the cerebral mass whose more intimate relation to cerebral action has seldom been disputed. The results may be subdivided into those crania which reach 21 and upwards; those which attain 20 inches and upwards in measurement; those which

attain 19 and upwards, and those which reach only 18 inches. Amongst those attaining 21 and upwards, we have merely the

Scotch.... 21 6-16ths
Irish 21 2-16ths

reminding us that the Scandinavian and his affiliated stock is a long-headed race.

Of those attaining to 20 inches and upwards, we have:—

The Swiss 20 15-16ths
The German........ 20 12th
T o Esquimaux 20 12th
The New Zealander 20 8th
The Greek 20 3rd

This I suppose will suffice, but I could give many more:—

The Native of Van Dieman's Land 20 12-16ths
The Seminole 20 1-10th
The Turk 20 8th

Amongst those attaining to 19 inches and upwards, we have:—

The Native of the Phillippines 19 14ths
The Chinese 19 8th
The Madagascar 19 8th
The Bosjeman 19 6th
The Peruvian 19 6th

Fine theory this, which places the builder of the ruined cities of America on a level with the naked, wandering, houseless, human baboon of Southern Africa:—

Hindoo 19 5th
New Hollander 19 1
Blackfoot Indian 19 14ths

Amongst those reaching in circumference of cranium proper, merely 18 inches and upwards, we have:—

The Flat Head Indians...... 18 15ths
The Circassian 18 12ths

One great source of error, however, in all these measurements must not be overlooked; we had no authentic means of separating the male from the female head; and, although generally, with but very few exceptions, the sex of the cranium may be determined on by an appeal to the position of the ear (during life), or of the meatus auditorius externus in the cranium, yet in the dark races especially, the precise sex cannot be so surely determined on. There can be no doubt that generally speaking, the *position* of the *ear* is the grand characteristic of sex; in the male, even in the mere infant, the larger part by far of the cranium is in front of the ear; in the female, the cranium is more nicely balanced, and the amount behind and before the ear are nearly equal. But every now and then we meet with a male head on female shoulders, and plenty of crania modelled as in women may be seen daily on the shoulders of robust, hard thinking, hard drinking men. Thus there is no absolute certainty when the cranium alone is examined, and I am willing, therefore, to give to the stickler for "bulk of head being the measure of genius," all the advantages he may seek from this palpable source of error.

A COURSE OF TWELVE LECTURES ON SKIN DISEASES

By D. J. CORRIGAN, M.D., Physician to the Whitworth, Hardwick and Richmond Hospital, Lecturer in the Dublin School of Medicine &c.

We shall commence with the exanthemata: this class contains the following orders:—

ROSEOLA Varieties. Æstiva, Infantilis

ERYTHEMA Varieties. Papulatum, Nodosum

RUBEOLA Varieties. Simplex, Nigra, Sine catarrho

SCARLATINA Varieties. Simplex, Anginosa, Maligna

URTICARIA Varieties.

ERYSIPELAS Varieties.

The first on the list is roseola or rose rash. This we find sometimes produced in summer by the sun's action on exposed parts of the body; whence the name, "roseola æstiva," or "autumnalis." We find it also frequently occurring in children owing to some derangement of the first passages, whence it is called R. Infantilis, and we as often find it arising as an idiopathic disease. This of itself is not of the slightest consequence as far as its treatment is concerned, but it is of importance for another reason, that you should be well acquainted with its appearance, because there are some important diseases, measles and scarlatina, with which you might be led to confound it, as the eruption of roseola very closely simulates those of the preceding affections. (Handing round some plates). Here you have an opportunity of perceiving the different phases of this rash; and you can, by the contrast strikingly displayed in these plates (one of rubeola and one of scarlatina) remark the difference which exists between roseola, measles and scarlatina. The skin in roseola is completely crimsoned over in these patches when it appears, and the portions of skin, the seats of the rash, do not present as much surface as you could lay a pin's head upon, which is not of a bright red hue; whereas both in measles and scarlatina, the skin in the interstices of the spots presents a natural appearance. Suppose a child brought to you with this affection, you might be puzzled at first to tell what it was, more particularly if it were that form of roseola where the eruption appears all over the body. But an attentive examination of the case will always enable you to decide correctly. In the first place we find that very young children, those in whom roseola oftenest appears, are not in general so soon attacked by measles or scarlatina, but on this you cannot place much reliance. In roseola we find an absence of the premonitory symptoms which usher in measles and scarlatina, neither do we find the peculiar form of efflorescence which accompanies measles, which we shall have to speak of hereafter. And lastly we have positive proof that the disease in question is neither scarlatina nor measles from the primary site of the eruption, which in roseola appears simultaneously over the body, while in the other two diseases, the face first becomes engaged, whence the efflorescence travels over the trunk and extremities. By paying attention to these points of distinction you run no risk of confounding this disease with either of the other two.

These are some symptoms which, occasionally accompanying the roseolous eruption, would lead you to infer that small pox was about to make its appearance. These are vomiting and pain of the loins. These latter symptoms, taken in conjunction with the appearance of the rash, would be very apt to puzzle one. If at any time you should be in doubt about such a case, suspend your judgment for twenty-four hours. This length of time will always enable you to arrive at a sure diagnosis. With regard to the roseola which precedes small-pock, I think that we should not call it by any such name. It is really and truly small-pock; these roseolous patches are nothing but congested clusters of cutaneous capillaries, which necessarily should exist ere the variolous pustules could be formed. And you will find these patches of so-called roseola subsequently becoming covered with pustules. In such a case as the last, the appearance of the peculiar protuberance of small-pock, in a few hours after the coming out of the eruption, will at once clear up the point.

Having thus discussed the points of distinction between roseola and those diseases with which it might be confounded, (its only essential points to be acquainted with,) we shall take up the next subject on the list—namely, "Erythema." Of this there are many varieties, of which there are but two, with which it will be necessary for me to take up your attention. One of these, "Erythema Papulatum" is an efflorescence attended with inflammation, which attacks the hands of grocers, bakers, &c. This erythematous efflorescence sometimes presents the incidental (not essential) complication of vesicles on th hands of those persons whom it attacks. The next variety is one which generally appears on the legs, and is called E. nodosum. This disease is most often met with in persons whose lower extremities are unprotected by warm clothing from atmospheric vicissitudes, and it is said to occur very frequently in persons whose constitutions have been broken down by intemperance and want. But I think that I have oftenest found this form of erythema in persons whose constitutions you could not say were actually broken down, but who nevertheless were in the habit of drinking to excess malt liquors, and whose digestive organs, from the wrong use of the above stimulant, were thrown into a state of chronic and acute inflammation. You will find such persons labouring under this form of erythema and complaining as follows: chilliness attendant upon its onset, and coming on every evening during the continuance of the disease; pains in the bones, and most particularly in the shin, or leg of the extremity affected. This naturally directs the patient's attention to the part, and on examination, he finds upon it, patches of an oval figure, and of a colour varying from a light red, to a deep purple or livid hue; these may appear along any part of the leg, but oftenest they are found running along the axis of the tibia. On passing your hand over these patches, you will find them bloated sensibly above the level of the skin, and presenting to the finger a distinct feel of fluctuation. So deceptive is this, that you might often be tempted to open them on the supposition that they contained purulent matter; but if you should act so rashly and unguardedly, you would find ample reason to regret it afterwards; for the incision made by your lancet, in place of healing kindly, would only increase the already existing mischief in a part so delicately covered by integument as the tibia; purulent matter would be formed in reality then, and you would have an ulcer to deal with, which you would find very difficult of cure, in a constitution so much deranged as that of those persons who are generally the subjects of this form of erythema. The oval elevated patches which the tibia presents in this disease, are caused by inflammation of the subcutaneous cellular tissues, which throw out a quantity of lymph mixed with fibrinous matter. This it is which causes the deceptive feel of fluctuation so likely to lead you into error. This disease might be mistaken for another, periostitis, when the grand object is to evacuate by a free incision the water, as soon as ever fluctuation can be felt. From this latter you will be able to distinguish it by the fugaceous character of the pains in the bones, and of the pain which the person feels in the part affected. These, he will tell you, are better one day, and worse on the next, here to day, and there to-morrow, there is no certain seat for the pain, and that it wanders at random over the limb. In periostitis, the abscess which forms, is invariably well defined and limited, while here these elevations are never well defined; they run to some distance, and blend insensibly with the adjoining skin, and cellular tissue; and these elevations feel just as full of fluid at their circumference, as they do in the very centre. By these means, you will be enabled to distinguish erythema from periostitis, the only disease with which it can be confounded, and from which mistake, were you to commit it, your patient would be liable to incur rather a serious injury. Now for the treatment. This consists in the application of stimulating lotions to the erythematous patches, for the purpose of causing absorption of the effused fluid, and of exciting healthy contractility in the debilitated capillary circulation. For this purpose I generally employ spt. camphoræ. The internal treatment consists in the first place in the administration of mild purgatives to clear out the alimentary canal. After this has been done, your next step should be the administration of bark in a state of effervescence, or in any other of the multifarious forms of giving it, which you may think best adapted to suit the exigencies of the case before you.

Measles come next after erythema. This is a disease which it is extremely important for you to be well acquainted with, as it frequently prevails as a highly dangerous epidemic. Of measles there are three varieties: R vulgaris, R nigra, and R sine catarrho. Common measles is divided into three stages—namely, the stage of incubation, that of premonition, and the fully formed. By the incubative or latent stage is meant the period of time which may elapse from the date of a person's exposure to the infection of measles until he actually sickens. From extensive and careful observation on this subject, which frequent opportunities of attendance on the disease have enabled me to make, I am led to think that this latent stage occupies, at

least, a period of 14 days. But, I do not confidently assert, that it is not longer than this period. I know that it never is shorter. From the experience which I have had in the study of this subject, I would be inclined to reckon 14 days as the general duration of this incubative stage, calculating as closely as possible from the time when the patient was first exposed to the source of infection. A knowledge of this fact will at once teach you the impropriety of giving a decided opinion, as to whether a child who has had measles, but who is in a house where others are ill of it, may not be about sickening, merely because a few days may have passed over since the child was first exposed to the infection, without its appearing. Make it then a general rule never to pronounce a decided opinion as to a child's freedom from the infection of measles, until a period of at least 14 days shall have elapsed since the child has been exposed to the source of infection: perhaps it would be prudent for you to be guarded in your opinion for even some days longer. The second or premonitory stage is ushered in by a sense of chilliness all over the body, which ends in rigors. These pass away more or less quickly, and are then succeeded by a state of reaction. Fever sets in. This is accompanied by coryza, running from the nose and eyes; pain across the frontal sinuses; to these is invariably added cough arising from an extension to the bronchi of the irritation existing in the nares and fauces: this extension of irritation producing in most instances the disease called broncho-pneumonia. In two or three days after, in addition to the already existing symptoms, others, the pathognomonic ones of the disease, make their appearance. These are stigmata, which appear on the face and neck of a bright red colour, and somewhat like flea bites, closely resembling them in fact; the only difference between them consists in the absence from the stigmata of measles of the central puncture so peculiar to the former. The first place in which these stigmata make their appearance is upon the back part of the pharynx, where they may be seen in most cases of the disease, fully 12 hours before they are visible on the face. They preserve, on the pharynx, the same irregularity which characterises their appearance on other parts of the body. These stigmata spread from the face and neck all over the trunk and extremities, and appear in semi-circular patches thus: (showing some plates descriptive of the appearance of measles) just as if you drew a number of semi-circular dotted lines all over the body, these lineated figures, crossing each other irregularly, while the skin in the interstices of these circles of stigmata presents its usual natural colour; this is the grand characteristic between measles and scarlatina, both of which closely resemble each other in the appearance of the eruption. The cough, which ushers in the attack of measles, is often of a peculiar character, possessing a ringing sound perfectly analogous to that of genuine croup. So striking is the likeness between them, that practitioners have often erred in making their diagnosis, and confounded the cough of measles with that of croup. It will be of the utmost importance to be able to distinguish both, and to tell with accuracy whether the cough you hear depends on croup or not. It will be important for you to tell, because the feelings of the mother, ever most acutely sensitive on the most trifling ailment of her child, will be materially relieved when she finds her apprehensions of croup were ill-founded. And for a more personal reason will it be important, because the parents of the child will naturally suppose you ignorant of the proper modes of treating the disease through its future stages, when you have made such an egregious blunder at the very outset. If you did make the mistake of treating this ringing cough for genuine croup, the error *might* not be one of any great importance: the only difference which it *might* make, would be, that the means of cure adopted need not have been so energetic. But the parents of the patient never look to this in cases where you may be in doubt as to the nature of the disease which you have to treat. An examination of the history of the case will always enable you to decide what it really is, whether measles or croup. In croup, you have this ringing sound preceded by fever of two or three days duration previous to its accession; while you very seldom have the coryza and watering from the nose and eyes which are such invariable accompaniments of measles. And if the eruption should be appearing in this latter at the time you are called in, you will have no difficulty in determining the nature of the disease, and in every case you will find this croupy cough of measles subsiding, as soon as ever the eruption appears. In genuine croup this ringing sound is never ameliorated at any stage of the disease; it continues to increase in intensity unless checked by the interference of art. In every case then where you hear this peculiar cough, conjoined with the other symptoms which I have mentioned, you should tell the parents, that croupy cough and breathing occasionally attend upon measles; all you will have to do in such a case, will be to treat the febrile symptoms "en masse," and wait until the day after developing the disease shall remove from the parent's mind all dread of croup. Modern improvements in the practice of physic have removed a great deal of the errors, which an acquiescence in popular opinion as to the treatment of this disease was sure to lead to. I allude to the popular plan of "forcing out the measles" as it is still called, by the administration at its onset of stimulating cordials, by keeping the patient wrapped up in warm bed-covering, and by keeping the room at a very high degree of temperature, and not allowing a breath of cool air to enter it; in fine by every means best calculated to excite and foster fever in the child. Modern improvements have done away with a great deal of this, but it still exists to some extent. It is generally remarked, that popular errors always take their rise from some point of doctrine originally based on experience and observation. It is so in the present instance; although the indiscriminate employment of heating and stimulating remedies cannot be too strongly deprecated, still there are cases of measles, where their employment becomes absolutely necessary. Unless such a plan of treatment is adopted, the child inevitably perishes. It becomes necessary with children of weakly delicate habits, who do not possess sufficient strength of constitution to oppose the primary onset or shock of the disease with vigour sufficient to produce subsequent reaction. This reaction does not take place; in other words the fever which should follow the stage of shock cannot set in, and the child is lost, sinks, in fact, through sheer debility. In many such cases we find convulsions occurring, owing to the congested state of the brain, which is induced by the vessels of that organ not possessing sufficient strength to unload themselves of the unusual quantity of blood which they contain. Here stimulants become just as necessary, and are given on the same grounds, as at the outset of some cases of typhus fever and pericarditis; where, unless we give them, the patients are sure to sink. In these cases, the application of dry heat externally, by means of warm flannel, coupled with some mild stimulant which shall determine gently to the surface, will be found highly useful. The sp. ammon. arom., in doses of a few minims, according to the age of the patient, is one of the best of this class of remedies; these means must be persevered in until the skin becomes warm—until the pulse rises; in a word, until the circulation gives proof of acting with increased vigour. The idea of the advantages resulting from that indiscriminate employment of the stimulating plan, namely, an increased and larger quantity of the eruption than would otherwise occur, is perfectly ridiculous. No advantage can be gained by this; and in the majority of instances we run the risk of inducing, perhaps, fatal mischief. We know, in small-pock, where no more than ten pustules appear all over the body, that the prophylacic effects of the disease are gained as fully as if the body were covered by them. In like manner here, the constitution is just as well guaranteed from any future recurrence of the disease by the appearance of a light eruption, as by one which would cover the whole body. Though we are not justified in forcing out the eruption of measles, still, when it does come out, we must take care that it is not repelled before its proper period, as such an occurrence would be sure to bring on a train of highly dangerous symptoms. In such a case, the employment of the warm-bath, joined with stimulating and diaphoretic medicines (those which are calculated to excite the cutaneous capillaries to increased vigour are to be preferred), will in most cases be successful in restoring the stigmata to the skin. It has been proposed to extend to the premonitory stage of measles, the treatment by cold affusion, which has been found so successful in a similar stage of scarlatina. But I am sure that this plan of treatment is highly injudicious, and I fully concur in the opinion of its ineligibility at this stage of measles, which has been tacitly pronounced upon it by the majority of well-informed practitioners, who have ceased to employ it. The advocates of the extension of the cold affusion to measles, seem to forget the very great disparity which exists between the membranes, the seats of disease in measles and scarlatina. In the latter it is the mucous membrane of the alimentary canal, which is affected, while in measles it is the lining membrane of the air passages. Cold, externally applied, we know to be productive of the most beneficial effects in the former class of disease, while in the latter, general opinion has pronounced it highly injurious, and as likely to lead to a severe aggravation of all the existing symptoms. This is the reason why cold should not be used either at the onset or progress of the disease of measles.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

We now proceed to paralysis, which is similar both in pathology and symptoms to that which constitutes apoplexy. Apoplexy is a sudden abolition of the sensorial functions, sensation and voluntary motion, and a partial abolition in many instances of the spinal function. Paralysis is an abolition or diminution of some part of these; sensation, for instance, alone, or motion alone, or sensation and motion of parts of the body, or sensation only, or motion only, in *one* part of the body; loss of voluntary power in some part or parts of the body, or loss of sensation and sensibility in some part or parts of the body. It appears in very different degrees. There are a few cases on record of general paralysis of nearly the whole face; yet without loss of consciousness. It seems difficult to understand how that can be: one indication that there is consciousness is voluntary motion, and you could not have that indication if it were complete. There was another case in which all sensation was abolished, except the action of one cheek, the motion of which was the sole means of communication between the individual and the external world; yet that sensitive patch was the means of indicating that the individual was conscious. By-and-bye, however, deglutition and respiration became affected, and death ensued. Generally, paralysis is much more partial than this. For instance, in *hemiplegia*, a longitudinal half of the body is paralysed, both in motion and sensation, or sometimes one alone. *Paraplegia* is paralysis of the lower half of the body; the transverse half, dividing the body horizontally; a loss both of sensation and motion. Another form of paralysis, more partial than these, is the loss of sensation and motion in one limb; and there is a still more partial form in which the parts supplied by one nerve are paralysed, as paralysis of the ischiatic nerve, or of the portia dura.

General paralysis may come on either as apoplexy does, by a stroke, or it may come on gradually, or what is called creeping paralysis, which may commence by the dropping of the eyelids—paralysis of the levator muscle in that part—or a toe, or a finger; or articulation becomes

indistinct, or some special sense, as sight, hearing, or the tongue becomes paralysed.

In hemiplegia, it is remarkable that the paralysis usually affects chiefly the extremities, more than the muscles of the head and face. Sometimes, as a consequence of apoplexy, when the patient recovers consciousness and the use of the brain, the sensorial powers, and sensation and volition, with regard to the body generally, he does not recover sensation and volition with regard to one part of the body, and hemiplegia is exhibited by the paralysis of the hand, the fore-arm, and the leg, the muscles of the neck and face being less affected; sometimes there is a drawing of the cheek and mouth on the paralysed side, so that when the patient attempts to open his mouth in mastication, the weakness of the paralysed side is apparent. If he attempt to blow with his mouth, the orbicularis gives way on the paralysed side more than on the healthy; and there is, more or less, a dropping of the eyelid, giving a sort of blank to that side of the face, a want of vigour, tone, and expression. This is not, however, the paralysis which most distorts the muscles of the face. The paralysis here produced is paralysis of the fifth nerve of the motor branch, but the expression which exhibits the most striking change in the countenance is that produced by paralysis of the *portio dura*. The tongue when protruded is commonly protruded towards the sound side, and the muscles of the extremities are affected more than other parts. This is a remarkable disease, obviously arising from the brain; it seems to take effect more on the distant parts of the lower and upper extremities, than on the parts supplied by nerves from the superior part of the spinal column. I believe the true cause of this is dependent on the destruction of the particular bundles of fibre which go to the lower extremities, the *optic thalami*, and the *corpora striata*. Now, I believe the true explanation of the effect produced by affections of the brain on the lower parts of the spinal nerves,really depends in a great measure on the irregularity that occurs in consequence of effusions and apoplectic clots in congestion, or effusions of serum causing pressure, and spread over a considerable surface. The permanent injury is not felt so much in the parts where the effusion lies, because there the matter causing the pressure is spread over a considerable surface, but it is felt in a diagonally opposite situation; and this, I believe, to be one cause why hemiplegia affects the muscles of the opposite side, whereas in many instances it has been observed to affect the same side as the injured part. If hemiplegia is not preceded by apoplexy it may begin gradually and creepingly, and the manner in which it becomes apparent is, that it is often preceded by quivering motions, and slight convulsions of the muscles; by a dragging of the leg, or numbness of the fingers. I have known pains complained of in the loins of the affected side, sensation and motion being exalted in many instances before they are abolished. This implies that excitement precedes the paralysis; and in creeping palsy the disease is more the effect of pressure, or cerebritis which is accompanied by ramolissement of the brain. This softening is found to be most commonly in the *optic thalami* and the *corpora striata*. Hemiplegia is therefore generally produced by disease within the head, not of the spinal marrow; although it affects the function of the spinal marrow, yet it is a disease affecting the fibres of the spinal marrow within the head. The diseases that affect the spinal marrow below the *foramen magnum occipitale*, usually are confined to one side. Anything producing pressure or irritation would be felt across the whole diameter of the spinal canal, and produce irritation or palsy below the injured part. Paraplegia is, probably, exclusively a spinal disease, and does not arise, in all probability, from disease of the brain, as is the case with hemiplegia. Paraplegia may be produced by the causes that produce apoplexy, congestion of the brain and the spinal cord, suddenly or gradually produced. Hæmorrhage occurring in the brain will be a cause of it, and, besides these causes of apoplexy in the brain, inflammation of the spinal cord may lead to paraplegia; cold, rheumatism, blows, and other causes may first of all be accompanied by symptoms of excitement of the functions of the spinal cord. Great pain is felt in the back, accompanied by tingling sensations along the course of the spinal nerves to the lower extremities. There is also the function of the spinal cord, the excito-motor power independent of the will, and it is remarkable how, in cases of disease of the spinal cord, this becomes excited when the voluntary excito-motor power is cut off. Suppose, for example, the whole length of the spinal cord, or the upper portion is depressed, either by a tumour or a clot of blood; the pressure cuts off the communication with the whole brain, but it does not impair the function of the spinal cord as an independent organ; it has its own excito-motor power, and is capable of being acted on by the incident nerves, and of being affected by the voluntary or involuntary muscles. Nay, more than this, when, owing to the sensorial parts being cut off, and the irritability of the muscles of the body not being exhausted by acts of volition, it becomes accumulated in these muscles, and the nervous power becomes accumulated in the spinal cord; and, therefore, in cases of clots causing paraplegia, there may be an exaltation of the true spinal function in these very parts; and the consequence is, nervous spasmodic twitches, convulsive motions, sometimes produced without any external cause. Under these circumstances the lower extremities may be beyond the influence of the will, or if you tickle them and irritate the nerves of the toe the patient is unconscious of it, though convulsive motion is produced, because the irritation is communicated to the central nervous organ, and the influence is transmitted back again —the reflex influence—to the posterior extremities, and convulsive actions are produced. The fæces from the alimentary canal, and the urine from the bladder, will excite these twitches and convulsions in paraplegiac limbs. This is one of the most remarkable phenomena of paraplegia; it is an epi-phenomenon superadded to paralysis, and which we could not explain without assuming an independent power of the spinal cord itself. When paraplegia is perfect there is an entire loss of power over the limbs, and when it goes beyond the degree I have mentioned before, it may not only press one part of the spinal column, and separate the spinal from the cerebral function, but it may injure the spinal function itself. Under these circumstances there is a loss of power over the organs beyond the influence of the will, the sphincters of the bladder and the rectum. No wonder, therefore, that in many diseases we find a complete destruction of these functions, though the spinal cord is often intact. Paraplegia may come on gradually; numbness, &c., gradually increasing until death. Where it affects the extremities it produces disease in the excretory organs, and the power of the sphincters by which the urine and the fœces is affected. The retention or irregular evacuation of these matters leads to various secondary diseases of an aggravated kind, and in paraplegia there is usually disease of the bladder and ultimately of the kidneys, which become diseased, probably, from the loss of power of the excreting apparatus; there is also flatulence and a tympanitic distension from the loss of power and tone of the peristaltic muscles. There is likewise in these extreme cases of disease, where not only the voluntary excito-motory function is destroyed, but in regard to the lower extremities, sensation also is destroyed, a tendency to slough. Sometimes it is possible to distinguish the seat of the chief disease in the spinal cord by pressure on the spinous processes of the vertebræ. Where there is excessive inflammation there is tenderness there, but this cannot be from the pressure on the spinal cord itself, but is merely from reflex sensation, from exhausted sensibility in the part. The plan of Hope of applying hot spinach answers in the same way, and the pain is complained of at a particular spot.

Can paraplegia ever result from failure of nervous power? The nervous power of the whole nervous centre is felt most in the lower extremities, because it is the most distant. Some cases seem rather to render the supposition not improbable. If the disease is high up in the back then there is paralysis of the intercostal muscles, and the respiration will be effected; that part of the inspiration which depends on the action of the intercostal muscles will be suspended, and the respiration is wholly diaphragmatic, and the patients are not only unable to breathe, but are unable to cough, owing to paralysis of every part of the body below the neck except the diaphragm, which is supplied by the phrenic nerve which has its origin high up in the spinal cord. The treatment of paralysis will very much depend on the causes. Where it arises after apoplexy the treatment will be the sequel to apoplexy; occasional cupping or blisters, or both, to the back of the neck, and sometimes setons or issues to produce counter-irritation. The same thing may be said with regard to the creeping palsy, but in many of these cases it is necessary to use depletion first, but not so freely as in the case of apoplexy,—until you see a change produced. Well then, when the symptoms of inflammation are subdued, and the patient remains hemiplegiac, there are various things to promote a return of the nervous power, not distinctly antiphlogistic. Strychnia has been applied with this view, because it has a stimulating influence on the spinal function, and it is of great use where the disease is in the spinal cord; tincture of cantharides I believe to be more useful than strychnia. It may be given in doses of from ten minims up to half a drachm. Henbane also materially promotes the return of the nervous influence. It has been given by Sir Henry Halford and Dr. Chambers. In paralysis, the treatment will very much depend on the origin of the disease. If it originates in inflammation, accompanied by occasional spasm or excitement, and increased sensibility and pain, and particularly, if there is any heat in the spinal column, or fever, then depletion by cupping about the neighbourhood of the affected part, or general blood-letting and the use of mercury and antimony, and other antiphlogistic stimulants are useful. These may be followed by blistering the spine, or counter-irritation applied along the course of the spine. The mercurial plan is decidedly useful. In these cases, too, where all the symptoms of inflammation are subdued, tincture of cantharides, and other stimulants, such as turpentine, in small doses, may be given, but not before the other remedies I have mentioned, because the bladder is apt to become inflamed. If there is any want of power of action in the bladder, and the urine is yet natural in appearance, and there are no symptoms of pain and tenderness, the tincture of cantharides often restores it. When the disease is old this is not to be withheld. Strychnia is useful in paraplegia, and the cases in which it appears to be chiefly useful, are those in which the muscles have lost their power in a great degree, but not entirely, and in paraplegia arising from connexion with rheumatic inflammation of the spinal cord, after the inflammation has been subdued by the measures I have mentioned, to which colchicum should be added, strychnia is decidedly useful in restoring the power of the muscles. This remedy should be given with very great caution; entirely in solution, and not in the solid form; the thirtieth part of a grain in nitric acid, gradually increasing it until some twitching of the muscles is produced. Partial paralysis may be produced by diseases in the nervous centre, but the more partial form of paralysis is more commonly produced by disease affecting the nerves, from tumours or some other causes, pressing on the nerves in some part of their course. The more partial paralysis arises from a local cause, and the same thing may be said where sensation is solely affected, or motion solely affected; however, motion alone, or sensation alone, may in a few cases be affected by disease within the spinal sheath or the cranial cavity. Cullen mentions a case in which one side of the body was affected with loss of feeling, whilst the other side was affected with loss of motion.

There is an irregularity I should mention in hemiplegia. Whenever you have partial paralysis, it is generally in the first instance, or in some part of its course, accompanied or preceded by some symptoms of irritation, and there are spasms

or pains connected with the nerve which is the seat of the paralysis; and the various circumstances which may produce this are congestion or inflammation of the nerve, and changes of structure following inflammation; such as softening, or a tumour pressing on the nerve; or tubercles in its course. All these different diseases are apt to cause irritation of the nerve, and, therefore, partial exaltation of the function before the nervous power is entirely abolished. The nervous function seems, sometimes, to be affected not merely by pressure, as from disease in the nervous trunks themselves, but by reflex influences from other parts. For example, the paralysis arising from dentition is partial; and there are many other cases of a similar kind in which the reflex irritations cause spasms, tetanus, and chorea; and they may be all said to be diseases of the nerves themselves. To-morrow we shall speak of some of the different forms of paralysis.

OBSERVATIONS ON VARIOUS DEBATABLE QUESTIONS ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.

By Dr. Clay, Piccadilly, Manchester.

No. II. Second Series.

(*Written expressly for the "Medical Times.*")

Subjects :—*Generally esteemed Natural Labours any thing but Natural—On the Secale Cornutum.—Manner of Exhibiting it—Its Action—Secondary Actions—Pelvic Pressure—Child's head—Use of the hair—The two Great Actions of the Uterus cannot exist in full energy at the same time—Pelvic Obstructions—Case—Observations on—Opiates, &c, &c.*

In my last observations, I concluded by stating that it was quite evident, that all that is required by the general definition of natural labour may be strictly accomplished, and yet the process *be anything but natural.* For instance, if from some cause the secondary longitudinal uterine fibres, from fundus to cervix, be put into action prematurely (that is before the primary or transverse fibres by their contraction have effected a sufficient dilatation of the os and cervix uteri) then the strict order of nature's rule is reversed, inasmuch as we have expulsive efforts before the parts concerned are prepared for them, whilst it is plain these expulsive efforts should commence *only*, subsequently to a sufficiency of dilatation. Scarcely any accoucheur of extensive practice but could furnish numbers of cases in reference to this point, in tedious labours, many of which are particularly characterised by premature expulsive efforts; now, it is impossible to class such labours as *natural ones*, the order of nature being directly reversed. This view of the subject shews in a strong light, the utter absurdity of exhibiting the secale cornutum at an improper season, *that is*, before a sufficient state of dilatation of the os and cervix uteri calls for it, when only it can be properly administered. This will be plainly understood when the real action of this valuable remedy is considered. It is only the too general application of it by inconsiderate persons, and the want of attention to the purity and freshness of the drug itself, that have brought the use of this remedy into unmerited neglect and disrepute; nothing can be more pernicious than the too general application of any drug (even the best in the Materia Medica), and its really good qualities are often hid amongst a host of evils arising from misapplication. In the application of the ergot, it is strictly necessary not to use any specimen that has been gathered more than *one year*, but it is generally found of all ages mixed together, *from the first to the fourth year.* The infusion is the only legitimate form for ensuring its good effects, and the rules for its application should be, when sufficient dilatation is effected, and there is a want or absence of expulsive contraction of the uterus; by these points, the ergot is a most safe and effective remedy. For further information on this drug I refer the reader to my papers in the *Medical Times* and *Lancet.* The action of the secale cornutum, however, is the particular object of our present enquiry; from long observation, I am convinced it has no influence on the primary, or transverse fibres of the uterus, but has a particular and direct influence over the secondary longitudinal or expulsive fibres; hence, the absurdity of exhibiting this remedy during the primary action of the transverse fibres, at least, until a sufficient degree of dilatation is effected; if it should be unfortunately exhibited before this period, it increases the exhaustion, and adds to the tedium of the labour, without any advancement of the process. The general law which produces the secondary contractions, is the more immediate pressure on the pelvic viscera, where those nerves are more freely distributed, which, when excited, produce the effects of expulsion. It must be obvious, the moment the dilatation is sufficiently advanced, the pelvic extremity of the uterus becomes more pointed by the slight descent of the membranes and head of the child, and it is this pointed character that facilitates its descent into the pelvic cavity, and enables it to stimulate the nerves, which produce the more direct efforts of expulsion. Up to this period of descent, and pressure on the pelvic viscera, the expulsive efforts have not had (or ought not to have had) any existence, that is, supposing the labour to have been strictly natural; but *from this* period the expulsive contractions continue along with the primary action, until the completion of all the circumstances connected with natural labour. And here I may observe, that there is, perhaps, another use for the hair of the fœtal head, beyond that of being a mere ornament for after-life, but a use, if I mistake not, which has not hitherto been noticed by obstetric writers; it is this: after the membranes are ruptured, the rougher surface of the child's head, coated with hair, stimulates more powerfully the nervous tissues of the pelvic viscera, and, consequently, adds to the energy of the efforts of expulsion. When the membranes are not ruptured, the surface presented to the pelvic pressure is of a much smoother character, and the irritation less, hence, it is always observed, how much stronger the efforts of expulsion are, after the membranes are ruptured from the cause above suggested. This leads to another very common occurrence, which all practitioners have often observed; if the membranes should happen to have been *ruptured prematurely* (this is, of course, before dilatation is sufficiently effected) there is an immediate commencement of expulsive efforts, *which, being premature*, is the foundation of a tedious process, but continually accompanied with strong bearing down efforts, adding to the exhaustion of the patient, without a proportionate advancement towards the completion of the process. The powerful stimulus of the child's bare head may be esteemed the origin of premature efforts of expulsion in very many cases of tedious labour. It would almost seem to be a law in nature, that the two actions of the uterus, that is, the primary transverse, and the secondary longitudinal, cannot exist together in their full energy at the same time; that the secondary is a natural sequence to the primary, and that whenever one action predominates, the other is on the decline, or so far weakened as not to progress in the work which it easily accomplishes when alone. There are many proofs of this in obstetric practice of which I shall avail myself in these papers. It may be urged, that if the views I have here put forward are founded on correct principles, *how does it happen* that (before the membranes are ruptured, or the head descends to form this pressure,) *the longitudinal fibres are sometimes in action*, and this often takes place in *what is termed natural labour* (though I contend such a state of affairs is anything but natural). What then is the cause of this secondary action taking the place of the primary? I have no doubt pressure is the exciting object, as the following case will, I think, satisfactorily show. Mrs. ——, of Ancoats, sent for me in great haste; I found her pains frequent, and strong, accompanied with powerful downward pressure; to all appearance, the case was likely to come to a termination forthwith; indeed, one of the attendants stated that I had only just arrived in time for the birth. On proceeding to make an examination, however, I found the os uteri scarcely any dilated, at most not more than the size of a sixpence, at the same time, thick, rigid, and unyielding, and the rectum loaded with hardened fæces. On enquiry, I learned that the bowels had not been moved for the three previous days. I ordered an emollient clyster, which had the effect of removing, almost immediately, a large mass of fæcal matter; this was no sooner done, than the pains altered in their character, the forcing, or bearing down, disappeared, whilst the transverse, or grinding pains, were substituted, but even these were not violent. I then gave two grains of solid opium in a pill, and waited some little time to watch its effects; in about an hours' time, all pains left her, and she began to sleep soundly; I then left her, hearing no further about the case until the third day after, when, about noon, her pains returned, but were directly the reverse of her former attack; they were now purely of the primary, or transverse character, and the dilatation of the os uteri going on favourably; about 4 o'clock, P.M., a full dilatation was effected, when the secondary action or bearing down commenced, which soon terminated the labour,—that is, in about five hours from the commencement at noon. This is but one case, of many, that have occurred to me, which I could easily give, but for the charge of being prolix. The points of consideration in this case are extremely plain. On my first visit the case *was*, in respect to the pains *unnatural*, that is, the longitudinal preceded the transverse, whilst the reverse ought to have been the order of strict natural labour. The longitudinal, therefore being prematurely excited, were mischievous. Then, as to the cause of excitement, not the slightest doubt exists on my mind, but that the pressure of the fæcal mass on the pelvic viscera, produced the reversed order of action in the uterine fibres. As a proof of this, I need only turn to the result of my first visit:—No sooner was the pressure removed, than those peculiar pains (the effect of pelvic pressure) were removed. The transverse only then existed, which also gave way to opium. The progress of the case was effectually stayed for three days; and, after that, when the efforts of nature were resumed, a strictly natural process occurred, and the case was happily concluded. I may observe also, particularly in this place, that in the exhibition of opiates, there is yet much to learn. Transverse pains are controllable by opium, whilst the longitudinal *are not*, or if so, to a very limited extent. I am convinced that attempts to give opium in the latter stages of labour are often futile—that is, when the longitudinal fibres are at work, and a full dilatation accomplished. On the contrary, I think opiates are too much disregarded in cases of exhaustion, where the transverse pains are premature or ineffective. There is another circumstance known to every practical accoucheur, which serves to illustrate this subject very forcibly, but which I shall reserve for my next article.

ON POISONING BY MERCURY,

By MM. Danger and Flandin.

(For the "Medical Times.")

Our former researches on metallic poisons having been so favourably received, we considered ourselves bound, not only to continue our enquiries, but likewise, as much as possible, to render them complete. We have already in several memoirs successively examined as poisons, arsenic, antimony, copper, lead,—in a word, all the fixed metals, and in order to complete the class of metallic poisons, mercury only remains to be studied. This substance will, therefore, form the subject of the following memoir.

It is hardly necessary to state, that among the metals, mercury is one of the most dangerous and powerful poisons which individuals actuated by criminal intentions can have recourse to, and comes immediately after, if not on a par with arsenic. One of its compounds, the bi-chloruret or corrosive sublimate, was long known under the name of *poudre de succession.* It was one of the poisons administered by La Brinvilliers, and was the most active among those discovered in the famous chest of Ste. Croix, when seized by Government. In 1613 it was through its means that the Count and Countess of Somerset made away

with Sir Thomas Overbury, while imprisoned in the Tower of London. The murderers tried no their victim the following substances in succession:—aqua fortis, arsenic, and powdered diamonds, lunar caustic, large spiders, and cantharides, and ultimately succeeded in their criminal design by giving corrosive sublimate in an enema; death took place in less than twenty-four hours after the administration of that substance.(1)

There is every reason to suppose that corrosive sublimate was known to the ancients, and prepared particularly by the woman who became infamous to posterity as the associate in the criminal acts of Nero, and who aided them with the poisons she prepared in the imperial palace. This substance, as well as numerous other mercurial preparations, are daily prescribed* as remedial agents, and may, in the hands of ignorant persons, be productive of serious symptoms, as is shewn by the facts recorded by Pibrac, Plenck, and Frederic Hoffmann, to which may be added several others that are not so well known. As an article of commerce and in manufactories, mercury, by means of its emanations, may prove fatal to miners, who prepare it, and to workmen who handle it without paying attention to proper hygienic rules. Under the threefold point of view of forensic medicine, therapeutics, and public hygiene, the study of this body and its compounds therefore presents considerable interest, and cannot but lead to useful applications. Without completely losing sight of the physiological and therapeutic questions, we have hitherto especially directed our researches to the examination of this substance with respect to legal medicine.

On this subject scientific works are not wanting. Opportunities of studying the therapeutic effects of mercurial compounds on man, followed by *post-mortem* examinations, have unfortunately occurred too frequently not to induce observers to make clinical medicine serve in the elucidation of facts appertaining to medical jurisprudence. Several ancient authors, Celsus especially, state that they have found mercury after death, in the metallic state either in the bones or in the soft parts.(2)

A German physiologist, Dr. Osterten, has published some experiments which tend to prove that when animals are poisoned by mercury introduced by friction with the unguentum hydrargyri fortius, the globules of that metal may, with the help of the microscope, be discovered in the parenchyma of various organs, in the blood contained in the vena portæ and vena cava inferior, and that it seemed to be present principally in the spleen, the liver, and the kidneys, and to be chiefly excreted by the two last.(3)

A member of the Academy of Sciences, Professor Dumeril, asserted long since that out of about two thousand bodies which he had dissected, or of which he had performed the autopsy, he had in eight or ten instances, found mercurial globules in the body.(4) To assertions so positive and so clearly indicated, a systematic incredulity has been opposed in the present day. But if, on the one side, Mayer and Marabilli were unable to find the metal in the principal solids or fluids of individuals who died during or after a mercurial course;(5) if Christison did not perceive it in the blood and viscera of rabbits poisoned by corrosive sublimate;(6) finally, if in 1826 Dr. Devergie obtained only negative results on analyzing the blood the saliva and the urine of patients, while they were undergoing the most active mercurial treatment at the Hopital du Midi, (7) still there is no reason why we should overlook the facts recorded by other observers, and especially why we should consider as valueless, analyses, the results of which are supported by the testimony of Zeller, Buchner, Schubert, Friedmann, Gmelin, and M. Cantu.(8) In physiology the exception is frequently very near the rule, and in the domain, to a certain degree unlimited, of clinical facts, it is impossible that one person should have seen every thing. To consider old observations as valueless, is not the way to enrich science; on the contrary, it is sometimes a means of impoverishing it.

To give to each his due, it must be confessed that the idea of the absorption of medicines and poisons does not belong to modern authors. It is as old as the healing art, and proofs are to be found, especially in Galen's works. Again, for those who are ignorant of this fact, and have called it in question, it may be added, that several *savans*, whose modesty prevented their proclaiming so loudly as we have done, their discoveries, (Wibmer, Lebkuchner, Gmelin, Tiedemann, Jourda Buchner, Schubert,) proved long ago, by chemical analyses, that copper, lead, mercury, iodine, &c., were absorbed and penetrated into the system, whence they were excreted by the kidneys. But modern observers may be proud of the direct application to forensic medicine, of the facts discovered long before by physiology. In this mode of profiting by useful discoveries, impartial history will assign to each what by right belongs to him, and certainly will not attribute to one individual what is the result of the researches of all, or at least of many.

As to the study of mercury considered as a poison, the only progress made by the moderns, is the discovery and use of Smithson's apparatus, which is composed of a thin plate of tin covered with a layer of gold, twisted into a spiral form, the former constituting the electro-negative, the latter the electro-positive element. When plunged into a solution containing mercury, decomposition takes place, and the mercury amalgamates with and whitens the gold. When this has been effected, it is sufficient to expose the apparatus to a sufficient degree of heat to volatilize the mercury, and obtain it in the shape of liquid characteristic globules.

When the authors gave the first description of this apparatus, it was thought to have removed all difficulties in researches for mercury in cases of legal medicine, as Marsh's apparatus did at a subsequent period for the discovery of arsenic. Curious coincidence—both came from England, and their use in France was very nearly becoming the source of the most serious errors. No one has forgotten that Marsh's apparatus indicated the presence of arsenic in the human body in its normal state; and on the first trials made with Smithson's apparatus, mercury was found where none existed, as the following fact will prove. An individual, desirous of having the exclusive sale of a remedy, proposed as a cure for syphilitic affections, a *rob*, which he affirmed to contain no mercury. Two chemists who were directed to analyse this substance, made use of Smithson's apparatus in their researches for mercury. Their astonishment, nay more, their triumph was great, when through its means, they thought they had unveiled the fraud of a quack, and consequently proclaimed publicly, that the pretended vegetable specific contained mercury. No doubts could be raised against the correctness of the analysis, the gold having been whitened. The inventor of the *rob* protested that the liquid contained no mercury nor any other metal, but in vain, he was not believed. Time, however, that great rectifier of human errors, demonstrated, that the gold had not been whitened by mercury, but by the tin proceeding from the electro-negative element of the pile itself. The precept was then given, not to be content with the change of colour of the gold, but to decide that mercury is present, only when globules of that metal can be obtained by heating the apparatus in a tube. The lesson ought never to be forgotten.

By the comparative examination of the various tests by which mercury could be detected, we became convinced that the galvanic or galvano-plastic power is the best. We were enabled, through its medium to discover mercury in solutions containing only one hundred thousandth part of that metal. We did not go beyond this, as it was the limit adopted in our preceding researches, and we are happy to be able to state that this metal, which not only is a very powerful poison, but likewise, in its various forms, a useful and frequently prescribed remedial agent, does not form an exception. It was not the galvanic apparatus invented by Smithson which we made use of in our researches; the principle on which it was constructed was alone retained. In toxicological researches, this instrument presented inconveniences which we sought to avoid. As has been already mentioned, the electro-negative element—the tin—could be dissolved in the liquid and whiten the gold, a fact, by which the expert might be led astray. Again, Smithson's pile is plunged entirely in the liquid about to be examined, and must remain there for a considerable length of time; and may not the tin be impure, since this metal cannot be so purified as the gold with which our experiments were exclusively performed?

The authors propose substituting the following apparatus for that invented by the English chemist. A vase, into which the liquid to be tested is poured, is placed on a stand of a peculiar mechanism, to which is fixed a species of funnel, ending in a very small tube, the opening of which is nearly capillary. This tube forms with the body of the funnel an angle of about 90 degrees. The vase, full of the doubtful liquid is inverted into the small funnel, and then, by means of a hinge in the stand, the apparatus may be so placed as to facilitate the escape of the liquid. In the evased part of the funnel, the electro-negative conductor of a pile formed of a single pair of Bunsen's couples, is placed; and in its aperture the electro-positive conductor is introduced. Both, at least in the portion which is in the liquid, must be of pure gold, and the extremities must be brought almost into contact with each other. The constant and unvaried pressure exercised by the vase (which performs the part of Mariotte's vase or an intermittent fountain) on the surface of the liquid, causes it to escape regularly drop by drop from the capillary tube. This may be increased or diminished *ad libitum*, by augmenting or decreasing the slope of the apparatus: but the authors recommend in ordinary cases so to regulate it that there may be an interval of about five seconds between each drop. The liquid thus obtained must be received in a small capsule. As soon as the pile is made to act, there is a more or less considerable disengagement of gas, indicating the intensity of the current, and the mercury contained in the solution is deposited on the gold of the electro-positive pole, and whitens it. Finally, in order to be certain that this colour is owing to the presence of mercury, the metal must be volatilized in a small tube by means of the lamp employed by enamellers.

Certain to be able to detect with this apparatus proportions of mercury as minute as it is given to chemistry to discover, the authors, to attain the end they had in view, sought to discover a method by which mercury could be separated from organic substances. A task surrounded by some

difficulty, for all the mercurial compounds and the metal itself are volatile at a low temperature. How could organic substances be destroyed without causing the poison sought after to be volatilized at the same time? Ought distillation to be employed? It is a slow and difficult operation and needs complicated apparatuses. Again, how could the animal matter be burnt without the mercury and its compounds disappearing? Toxicologists have, it is true, proposed several methods by which carbonization or combustion might be performed, but none have been sanctioned by experience, and in a practical view, no one has sufficient confidence in them to assert that through their means they could, in cases of poisoning, discover mercury with as much certainty as arsenic, copper, or any other metal: a result that ought to be attained.

The process of carbonization proposed by the authors, is now of general use in medico-legal experiments, and they sought to render it applicable to researches for mercury. Success attended their efforts, and that without being obliged to have recourse to distillation, an operation very difficult of performance in toxicological questions, which sometimes must be solved in a positive manner.

After numerous trials, the following is the method adopted by the authors. The animal matter is liquified at a temperature of about 21·°, by means of a third or one half of its weight of monohydrated sulphuric acid, in the usual way. This obtained, and it requires not more than an hour and a half or two hours, the capsule must be taken off the fire, and its contents allowed to cool a little. It must then be placed in a fire place, so as to permit the gases disengaged to escape up the chimney, and small fragments of saturated chloruret of lime must be thrown into the carbonized liquid, stirring it all the time with a glass spatula. In proportion as the liquid grows thicker and whiter, distilled water is added to favour the action of the chlorine, and this must be continued until the liquid to be filtered is perfectly or almost colourless. The quantity of chloruret of lime necessary to obtain this end is always nearly in a ratio with the quantity of sulphuric acid employed to liquify the animal matter. Thus for four ounces of liver, on account of the bile and the fat contained in that organ, two ounces of sulphuric acid and an equal quantity of chloruret of lime are requisite; seldom more. The matter thus whitened and brought to the consistence of chalk, must be moistened when cold with absolute alcohol, in order to be more certain of obtaining the mercurial compound; distilled water is next to be added, the liquid filtered, and the precipitate washed several times. If the liquid thus procured is too considerable, it must be concentrated by evaporation, and then submitted to the galvanic current in the apparatus above described. Experience has proved that the voltaic current facilitates the precipitation of the mercury on the gold wire, or at least that it shortens an operation, which otherwise would require a considerable time ere it could be accomplished.

The metal obtained on the electro-positive extremity of the conductor of the pile, the gold wire, in order to remove all fatty matter, must be washed with ether or boiling alcohol, and dried, ere it be placed in the tube in which the mercury is to be set free. This tube must likewise be carefully prepared so as to avoid the humidity which sometimes remains, and which will then tarnish the globule of mercury—sometimes extremely small—which is to be made visible.

This process has already undergone the test of experience, so as to enable the authors to judge of its value in cases of poisoning; it not being requisite to take more than about four ounces of the liver of an animal poisoned with corrosive sublimate, to obtain a quantity of mercurial globules easily appreciable. It will therefore in future, by following the method here recommended, be as easy to discover a crime committed with *la poudre de succession* or corrosive sublimate as with arsenious acid or any other metallic compound. In a second memoir, the various questions relating to the action of mercury its compounds, as remedial agents will be examined.

ON UTERINE AND OVARIAN DISEASE

By Dr. Lewins.

In my former communication, I did not intend to give any decided opinion, on the propriety or impropriety of *ovariotomy*, but to defend an old friend from an imputation which I knew to be erroneous—and to express *his* opinion—that of Sir Charles Bell—and that which I believe to be entertained in the northern metropolis, founded on the result of cases operated on in Scotland. For my own part, I can conceive ovarian disease that would render extirpation expedient, but during a professional life of 30 years, in extensive private practice—and, long connected with a medical charity, where many thousand patients are treated annually, no case of that description has come under my observation. When I reflect on the little constitutional derangement produced in Mrs. C—'s case, when the cervix uteri was amputated by Professor Simpson, on the statements made by Osiander and others, in reference to the subject under consideration, I am inclined to think that it may occasionally be justifiable to remove the entire organ,—*anceps remedium melius est nullo*—in a disease so dreadful as *scirrhus uteri*.

You are mistaken in supposing my son's paper, No. 147 of the *Edinburgh Medical and Surgical Journal*, to refer to a case, where *he* excised the uterus. He never did so—the paper alluded to is an interesting report of the history of a case, in which the cervix uteri had been amputated by Professor Simpson, as recorded in the previous number of the same periodical—and of the patient's accouchement, which occurred thirty eight weeks, exactly, from the day of the operation!

I had the pleasure of learning by a late letter from Professor Simpson, that the individual continues to enjoy good health. Five years have nearly elapsed since the excision of the cervix uteri. In the annals of medicine, as was remarked by Dr. Robert Lewins, there are few cases which afford more striking and gratifying proof of the triumph of our art over a disease, which, from its nature and seat had by British surgeons, been considered desperate—and beyond the reach of human aid.

It is extraordinary that whilst such able men as as Mr. Lizars and Dr. Clay have been directing their attention to ovarian disease with a degree of zeal creditable to them as practitioners of the healing art, and whilst both of them have extirpated ovaria with great dexterity, neither have, so far as I know, amputated the neck of the womb, an operation much oftener, I imagine, requisite. Ambrose Paré adverted to the possibility of performing it, and Lauvariol actually proposed it in 1780. Wrisberg, Schlessing, and Ruvel, in Germany, and Montaggia in Italy, have since recommended the operation referred to. But Osiander of Gottingen appears to have been the first who performed this operation. In 1817, soon after the promulgation of Osiander's success in this country, I, in consultation, proposed that the cervix uteri of a patient labouring under disease of that part should be amputated—a proposal, however, too bold for the Scottish surgery of that time. The individual died a premature and lingering death, some twelve months afterwards. Dupuytren, Recamier, Colombat de l'Isere, and Lisfranc, are the French surgeons, who have particularly distinguished themselves, as operators in this department.

The late distinguished Dr. Ingleby, of Birmingham, amputated the neck of the womb, in two cases. The disease in the one was cauliflower growth, accompanied by hæmorrhage, serous discharge, dropsy of the extremities and face—with general anæmia, and in the other a bleeding cancerous fungus. In the former case thoracic inflammation came on in a few days after the operation, of which the patient died,—in the latter the person, who was almost moribund prior to the operation, became apparently almost quite well, got actually fat, and remained in good health for a year. The disease then returned, chiefly in the vagina and bladder, in consequence of which she died. The fact of Dr. Ingleby's having performed the operation was not known to the profession when Dr. Simpson performed it, so that the same credit is due to him, as if he had actually been the first British practitioner who had done so—besides *his* case is the one, in the annals of our country, which establishes the important fact, that the neck of the womb may be amputated with much more facility than was imagined—and that restoration to health and vigour of the system, and what is more astonishing, of the peculiar functions of an organ so vitally important in the female economy as the uterus, may be the *immediate* effect.

I would take this opportunity of impressing on the minds of medical practitioners the importance of early and accurate examination by the speculum in all cases of suspicious vaginal disease.—Cases similar to that operated on by Dr. Simpson are, I suspect, frequently treated by the routine practitioner as simple menorrhagia, or leucorrhœa, until a disease is gaining ground, which, ere its true nature is ascertained, has passed the boundary when it is proper to attempt a cure by extirpating the morbid structure.

The case above referred to *had* been treated as one of menorrhagia, previously to my seeing her. On examination per vaginam, I at once detected the real nature of the malady. By my advice, the very erudite professor of midwifery in the University of Edinburgh was consulted, who instantly confirmed the opinion I had previously expressed, and with me urged the imperative necessity that existed for the immediate excision of the diseased part, to which the interesting patient submitted with affecting resignation, and the result happily was a speedy and complete restoration to health and vigour.

That a *remembrancer*, in regard to the employment of the speculum is not superogatory, may be inferred from the fact, that there are districts in England, and towns containing upwards of 10,000 inhabitants, where a speculum vaginæ is not to be found amongst the "implements of art," of any practitioner. When on this subject, permit one, through the medium of your publication, read, I believe, by a larger number of general practitioners than any other periodical of the present day, to record the following valuable remarks on the use of the speculum, by a physician second to none in Europe for profound knowledge of uterine disease. "In some instances," says Dr. Simpson, the Edinburgh Professor of Midwifery, "examination by the finger, may be sufficient, but in every doubtful case, the speculum should also be resorted to, if there is any affection of the vagina or cervix uteri. We have found it often confirming, and not unfrequently also changing and rectifying the opinion which the mere tactile examination had led us to adopt. In this country, great difficulties have been placed against the more general introduction of the speculum into practice in consequence of the disagreeable and revolting exposure of the person of the patient, which is usually considered necessary in its employment. We have latterly in our own practice endeavoured to obviate this very natural objection by teaching ourselves, to introduce and use the instrument, when the patient was placed on her left side in the position usually assumed in making a tactile examination," (as during parturition) "and with the nates near the edge of the bed. We strongly recommend our professional brethren to follow this plan, as by it, with attention to the management of the bed-clothes, we have found that the instrument can be perfectly employed with little, or indeed without any exposure of the body of the patient. The speculum is introduced easily without the assistance of light, and the mouth of it only requires to be afterwards uncovered, in order to enable us to examine the cervix uteri, and upper part of the vagina. We have made trials of many different forms of specula, and find for almost all purposes, that of Ricord by far the most manageable. In exposing the cervix uteri for the purpose of drawing blood from it by scarifications" (a most efficacious practice) "in cases of chronic congestion, and metritis, we have occasionally used a tubular speculum with advantage, but even in this case the doubled-bladed instrument is equally useful, and in some instances preferable."

Most cordially I add my testimony to a know-

ledge of the fact, that the speculum vaginæ may be employed without the least indelicate exposure of the patient; and that by its use light may literally be thrown on the cervix uteri, which is of the most essential importance in the treatment of the diseases to which it is obnoxious.

ON PARALYSIS, WITH LOSS OF SPEECH, &c.

By G. SAYLE, M.R.C.S., Lynn, Norfolk.

Formerly Curator of the Anatomical Museum in St. George's Hospital School.

As an accurate knowledge of the injuries to which the head is subject, and the different treatment, is essentially* requisite for the surgeon, so is a thorough understanding of the diseases of the brain and its coverings, equally important to the practitioner in medicine. The following cases, proving certain results from ascertained causes, may be not altogether uninteresting, more especially, as we find "our knowledge is imperfect as to the probable situation of the cerebral lesion in cases of this description." Two of the subjoined cases came under my immediate observation, and in both I had the opportunity of a *post-mortem* examination. The third is extracted from the *Dublin Journal* for January, 1845, to which, with an interesting paper thereon, it was communicated by Dr. Steele. Although there was no *post-mortem* examination in Dr. Steele's case, the symptoms are so exactly identical with mine, that I think it impossible the similarity of all should be objected to.

Case 1.—Sarah Coppin, æt. 69, was attacked in 1842 with an apoplectic fit, the recovery from which, extended over a long period of time. It was attended with loss of speech and paralysis of the right side; the latter entirely disappeared, but the voluntary powers were ever weak afterwards, and the speech for some time following the attack was faulty; *i. e.* the *mind* apparently remained entire, as far as regarded the knowledge of external objects, but the power of applying their proper names was lost. In September, 1844, she was suddenly seized with a second attack, when I was called in, and found her right side again paralytic, accompanied with loss of speech. In a day or two they returned under the application of a few leeches to the back of the head, and the bowels acted upon by aromatic purges. The recovery left her rather weaker, yet exactly similar to the first attack, as far as I could ascertain. She had now a perfect command of utterance, but continually misrepresented her ideas; to wit, any hour of the day, on looking at the clock, she would call 14 or 16, or something as absurd; a door, a window, and so on. As a proof of her consciousness of being wrong, she would occasionally speak of her "distressing situation." She remained with little alteration, until the 5th of December, when a third and more violent attack, producing total paralysis, ended fatally in three days.

Post-mortem Examination.—Body emaciated, muscular system relaxed and flaccid.

Cranium.—The membranes of the brain presented nothing remarkable. On the surface of the brain, situated about the posterior of the middle third of the left hemisphere, corresponding to the posterior of the parietal fossa, was a blackish spot* of extravasated blood, as large as a sixpence, produced by exosmose, as no ruptured vessel could be discovered. At an inch, or an inch and a half from this farther backwards, was a dingy yellow substance,† of the size of a horse-bean, filling up an absorbed portion of brain. On cutting down the right hemisphere, a large coagulum of black blood ‡ was seen emanating from the striated body on that side.

Case 2.—Elizabeth Belchambers, æt. 81. Had enjoyed pretty good health until May, 1844, when she suddenly lost the use of her right side, with total loss of speech. Motion was never *entirely* recovered, but the power of speaking returned in a few hours, with the same inability, as in case 1, to apply proper names to certain objects, so much so, that the nurse "never thought her right afterwards." The general health continued remarkably good. Five months afterwards she had a second attack, from which time the speech was altogether lost. Motion in her right side was scarcely perceptible; she was perfectly aware of every object around her, and would mourn dreadfully, whenever I condoled with her on her lamentable state. The constitution began to break up in January last, and on the 9th February she died.

On examining the head, the dura mater was found very adherent to the cranium. The membranes were healthy. Two spots of dark brown blood,* the largest the size of a franc piece, occupied the anterior and posterior margin of a space on the brain, corresponding to the parietal fossa; the whole of this imaginary circle was smeared over with a lighter coloured blood.† The substance of the brain was firm, and presented no extravasation in the interior. No ruptured vessel could be found. The body was much emaciated.

Case 3.—On the 14th Nov., 1843, I was summoned to the bedside of a gentleman, aged 25, having a laborious situation in a government office, who, whilst there engaged in his usual duties was suddenly attacked with confusion of ideas and loss of the power of utterance. I had attended him, about a year previously for an apoplectic seizure which commenced with imperfect articulation and mental confusion. These were then however, transient symptoms, but paralysis of the right limbs soon followed, yet at the period of the present attack, their strength had completely returned. In the July preceding, his speech became again affected, and several symptoms premonitory of another seizure presented themselves, which after treatment disappeared without any injury, and he remained in perfect health up to the date of the last attack. I found him on that occasion affected with general stupidity and inability to utter an intelligible word. There was no paralysis; he swallowed easily, and appeared to suffer from nothing save a slight head-ache. Being unable to answer any question put to him, I procured writing materials, hoping that he might convey his ideas by their means, but after several attempts at writing, he was obliged to relinquish it as impracticable. In all particulars, however, he continued to improve up to the evening of the seventh day, when he appeared to have become considerably worse than he had been previously; drowsiness had gradually set in, and at the period of my visit he could scarcely be roused—his pulse too but 40 in the minute; the right limbs were much weaker than the left, the mouth was drawn to the left side, and the tongue when protruded tended towards the right. In consequence, however, of having employed the remedies usual in such cases, I was pleased to find on the following morning, that all immediately alarming symptoms had disappeared. The drowsiness had vanished, his intelligence had in part returned, and his pulse had rather quickened, but now his power of utterance was *nearly* extinguished, and the right limbs were almost completely paralysed.

In all respects however, he soon improved save in his power of speech, which, with the exception of an occasional word or short sentence was obliterated. His attempt at writing was equally faulty, and even to his name he could scarcely form a resemblance, unless it were first written him, and then he copied it but imperfectly. His powers of calculation were likewise lost, but the recollection of persons was entire, as also his memory of music, &c. Three weeks after the attack he was comparatively well in health, and although the faculty of speech was still nearly lost, he could get through a game of backgammon, and would occasionally apply proper names to things, and hum a tune.

These cases go far to prove—

1st.—That where a person suddenly becomes paralytic, losing for a short time voluntary motion of one side and power of speech, the former being in a day or two nearly restored, and the latter, as far as speech is concerned also, although the power of applying proper names to objects is lost; pressure on or in a small portion of the grey matter of the brain exists, and that that pressure occupies, for the most part, a situation corresponding to the fossa of the parietal bone.

2nd.—Where motion is partially restored, but the power of speech never regained, although the general health continues good, that the producing cause is the same, but the extravasation occupies a much greater circumference.

3rd.—That persons pre-disposed to this affection are generally those advanced in life, of an anœmic, lean, spare habit of body, produced either by over anxiety of mind, long continued watching, a sedentary calling in life, or any other occupation producing a debilitating effect upon the constitution.

It must be evident our first object in the treatment will be to recover the patient from the primary attack, and the means most likely to accomplish such an end, are those recommended in anœmic apoplexy, to which this species of disease must evidently belong. The recovery depends in a great degree upon the severity of the primary attack, and, supposing the patient to have overcome it, our attention may then be directed to the loss of speech. "Medical writers," says Dr. Steele, "have occasionally recorded examples of this affection; few of whom, however, have examined into their nature with sufficient care or philosophical accuracy. The majority of these writers have ascribed the loss of speech to a defect in memory, or, to use Dr. Osborne's words, to a 'forgetfulness of the art of using the vocal organs.'" Which cause soever it may be, the cause producing it remains, although in course of time it becomes altered in character, as is related in the first case; but, since we cannot by any means remove it, the measures recommended by Drs. Osborne and Steele can avail but little, *i. e.* teaching the alphabet anew by the patient repeating letters after you, as it must depend entirely upon the amount of extravasation whether speech is partially or altogether destroyed. Where the brain is very little implicated, habit appears to overcome the deficiency, and the power shortly following the attack of only uttering words, is capable of being extended into sentences. Our great aim should be, the prevention of a second attack by enjoining quietude for the patient, ordering mild aperients, and a generous diet.

PROGRESS OF FRENCH SCIENCE.

FROM OUR OWN CORRESPONDENT.

Paris, April 3d, 1845

On Accidental Retraction of the Limbs; (1) by Dr. Morel Lavallée, (continued.)—II. PATHOLOGY: 1º *Seat.* Notwithstanding the difference of their nature, the three species of muscular retraction manifest themselves chiefly at the extremities of the limbs, becoming less and less frequent as they affect parts situated nearer the trunk. They are most commonly met with in the hands and feet, or all three may be found united, as in the case of a patient of Dr. Vidal de Cassis. In these two parts, retraction of the fingers and toes, of the wrists and insteps, may be produced simultaneously by the muscles, by the aponeuroses, by sub-cutaneous bands, and by cicatrices; all these causes act with an equal degree of frequency, perhaps because the parts endowed with greater mobility and activity, are from their peripheric situation as well as by their ordinary functions exposed to the influence of external objects. Thus, to quote a single instance, if the palmar aponeurosis is forcibly compressed, when an instrument is held in the hand, it is equally acted on when that extremity touches an incandescent substance, or is extended, to press the rest of the body when a person falls into the fire. After the feet and hands, the next in frequency are the knees and elbows, the former especially, with respect to muscular and fibrous retractions, which originate in the diseases of the articulation. For

* The cause of the second attack.
† The cause of the first attack.
‡ The cause of death.

* The cause of 1st attack. † The cause of the 2nd attack.

(1) In the two preceding numbers, instead of "on accidental *contraction* of the limbs," read "on accidental *retraction* of the limbs."

the hip, the same circumstance, added to the frequency of inflammations of the pelvic organs and their connection with the articulation and its muscles, causes the retraction of this region to be more frequent than those of the shoulders. In these cases, it must be understood that cicatrices are not included. The retractions owing to the last mentioned causes, are situated almost always on the anterior surface of the limbs; for the upper extremity the same remark is applicable to those produced by the normal tissues, thus the fingers, the wrist, and the elbow are bent, and the arm is drawn forwards and inwards. In the lower extremity, on the contrary, in most cases, the retraction in the instep and knee takes place behind, the thigh alone being pulled forward by the normal or accidental tissues. As to lateral deviations, they are seldom met with, existing perhaps only internally or externally in the foot, (*pied-bot*,) in the hand (*main-bot*), and in the angular flexion of the knee especially inwardly. Here the three causes may act, though they are mostly produced by the muscles, and more so when the disease is situated in the foot. Syphilitic retraction seems almost exclusively to affect the flexor muscles of the elbow, a fact observed by Dr. Ricord.

2° *Pathology of the retracted tissues or organs by which retraction is produced*:—(*a*) *Muscles*. While studying the etiology of this disease, the various physiological and nutritive changes which take place in the muscular system, so as to cause organic shortening were examined; there remain to be examined those which manifest themselves when this morbid contraction has kept the parts more or less completely inactive, and which are discovered only by means of the scalpel. To the diminution in length is soon added that of size; the fleshy portion decreases more and more, so much so that the belly of the muscle disappears completely; thus in the *pied-equin*, the calf of the leg no longer exists, and the tissue which is of so bright a red colour in athletic persons diminishes gradually in intensity with the vigour of the constitution, until it reaches an extreme degree of debility, becomes pale, is infiltrated with fat or degenerates into a fatty, but never into a fibrous tissue. What led that distinguished observer, J. L. Petit, to mention so erroneous an opinion, was, as has been already stated, a superficial examination, and the limited knowledge practitioners had of pathological anatomy at that epoch. The excessive diminution of the fleshy part of the muscles, causes the fibrous parts to appear increased and more apparent, and encroaching on the red fibres, besides which these last being paler, present a greater resemblance to the former. This explains the origin of this evidently erroneous opinion, since no author of any importance has ever mentioned having witnessed this transformation, still such a result might be admitted, for is it not almost as physiological as the fatty degenerescence. It would be still more probable if the muscle was destined to present a passive resistance and act the part of a ligament, as in certain unreduced luxations, in which a false articulation has been formed. Here, when the retraction has reached its utmost limits, it has no effort to support, but merely to fill up a certain space, and is not fat, the substance chiefly employed in performing such an office? These are the changes which are produced by long standing and serious retractions; they are however less in recent and consecutive shortening.

(*b*) *Normal fibrous tissues*.—In the muscles the atrophy is complete, in the aponeuroses on the contrary, atrophy and hypertrophy exist at the same time, the former in length, the latter in size, as if the one increased at the expense of the other. The only lesions which have been attentively studied are those of the palmar aponeuroses; these are also the most frequent, and the following remarks consequently apply to the description of these lesions. But before doing so, in order to have an exact idea, and distinguish between what appertains and what is foreign to this membrane, it is indispensible to know its normal disposition, with respect to which there is a difference of opinion, although it has been examined by a great number of anatomists. The most important points in the description of this membrane, are the number of the fibrous bands, their texture and their insertions. According to M. Maslieurat Lagemard, who carefully and very frequently dissected it, the central portion is divided into seven distinct bands; three are cutaneous, and are inserted into the skin at the metacarpal extremities of the phalanges, and produce those soft elevations visible in the palm of the hand; the four others, also longitudinal, correspond to the four last fingers, and each, instead of bifurcating to encompass between its two divisions the tendons of the flexor muscles, present a sort of ribbon, somewhat thinner in the centre than at the sides. Now, and this is the most important point, where do these bands terminate? In the inferior transverse metacarpal ligament, according to Professor Blandin, and Dr. Malgaigne; Professor Cruveilhier states, that they descend to the anterior phalango-metacarpal ligament; Dupuytren, to the sides of the first phalanx; and M. Maslieurat, to the sheaths of the tendons of the flexor muscles with which they are continuous. If, on so simple a subject, such a diversity of opinions exist, may it not be concluded that the termination of these bands is either variable or vague, or without precise limits? Besides, Professor Gerdy has discovered at the base of each finger, in the thickness of the cutaneous folds, which form the commissures, semi-circular layers, which unite together the longitudinal bands, and cross each other like an X.

This is the normal condition, and the pathological will next be examined. In 1831, the author dissected with great care, a hand which was considerably retracted, and which presented the following lesions (2). The thumb was drawn into the space between the indicator and medius, by a retraction of the tissues surrounding the phalango-metacarpal articulation, produced by a fibrous band, extending from the middle of the outer edge of the palmar aponeurosis, and inserted into the outside of the base of the first phalanx, on which it extended; the articulation of the first and second phalanges was bent at right angles, owing to the presence of a very powerful fibrous band, which had two origins, the first from the inner edge of the central portion of the aponeurosis, the second from the capsule of the phalango-metacarpal articulation; it had, also, two terminations, the one from the internal edge of the base of the second phalanx of the finger, and the other on the inside of the second phalanx of the slightly retracted annularis; the second phalanx of the little finger was thus comprised between the two. On these fingers there was nothing corresponding to the normal bands. A different result was remarked on two hands dissected by M. Goyraud; in both, the palmar aponeurosis presented its normal condition, as well as its bands. The description of the left hand alone will here be transcribed, that of the right being too complicated to be understood without the help of a plate. "The medius and annularis of the left hand were retracted; the former was kept *in situ* by a single band which proceeded from the inferior portion of the anterior surface of the palmar aponeurosis, and terminated at the upper part of the external edge of the second phalanx, which presented, where this band was inserted, a tubercle similar to those observed on bones where tendons are inserted. These bands caused the retraction of the medius; the first, short and thick, arose from the external and posterior edge of the band of the annularis at about four lines from its lower insertion, proceeded backwards and outwards, and was inserted at the distance of about half an inch on the sheath of the tendons of the flexor muscles of the medius, opposite the superior extremity of the first phalanx, keeping the medius and annularis somewhat inclined towards each other. From the inferior edge of this band two others, long and thin, arose, and descending convergingly before the first phalanx of the medius, they were inserted into the same part of the sheath of the tendons of the flexor muscles at about the middle of the second phalanx. The upper band received superiorly, and towards the extremity of its internal edge a very thin band, which proceeded from the languet of the aponeurosis, inserted in the inner edge of the base of the first phalanx of the annularis, and which, in order to reach the transverse band, crossed those of the annularis, very obliquely from above downwards, and from within outwards. All the fibres of these bands were parallel; in the recent state were very resistant, and inextensile, and possessed the whiteness and the aspect of a ligament.(3)

These two cases may be considered as examples of the two principal varieties of retraction of the fingers produced by normal fibrous tissues. One consists of an hypertrophy and shortening of the bands of the palmar aponeurosis, whether inserted or not on a level with the division of the fingers. Their prolongation on the first and even on the second phalanx, does not authorize our attributing their existence to a pathological condition, or considering them as supernumerary bands added to the edges of the palmar aponeurosis; according to such an hypothesis, the ordinary fibrous bands ought to be met with. Might not the excentric displacement of the insertion be explained in the following manner? It may be concluded, especially if the termination indicated by M. Maslieurat be correct, the small band being inserted into the sheath and parallel to the phalanx, that the retraction once begun, the band is detached gradually from the sheath, as the finger is bent more and more, forms an acute, and tends by degrees to become a right angle. This takes place in the same way as the distance of a tendon of a flexor muscle, and the bone would increase, if the sheath was opened from above downwards, the finger being bent. The tension of the bands from the efforts that are made, facilitates also this displacement which is at the same time both mechanical and vital. It is however, with considerable reserve that the author submits these theoretical views to the judgment of the medical public.

The second species is established by M. Goyraud's anatomical preparation, and by a case observed by professor Gerdy on the living subject. Since the normal aponeurosis existed at the same time as the contracted bands, these were probably caused by a fully developed condition of the fibrous rudiments which constantly accompany the aponeurosis. But as Sanson justly remarked, one fact does not annul another, therefore the possibility of the fingers being retracted by cellular tissue, so condensed as to form bands, does not preclude that produced by hypertrophy complicated with shortening of the normal bands, with or without any change in their insertion. In this case; *i. e.*, the change in the insertions, it is easy to conceive that the *languets*, though apparently elongated, presents in reality a contrary disposition, being too short for the space nature destined them.

Paris, April 10th, 1844.

Fistula of the Urethra cured by the Autoplastic Method, by A. J. Jobert de Lamballe, D.M.P., M.A.M., &c.—This case which has terminated successfully, may be added to the numerous others in which the skilful surgeon of St. Louis has performed this operation. A. D. ætat 37, from Lille, hatter, entered the wards of Dr. Jobert de Lamballe, on the 1st November, 1843, on account of a fistula of the urethra, with which he had been affected four years previously. The disease came on after a retention of urine caused by fatigue, and which rendered catheterism necessary. The genital organs became all at once very much swollen, and highly inflamed; the urethra burst, and a fistula was established at the root of the penis, just before the scrotum. Four years after this, he came to Paris, entered a hospital and remained there two months without any operation having been attempted. On his return home, he contracted syphilis—chancres and buboes followed by a papular syphilitic erup-

---

(2) The anatomical preparation was given by the author to Dr. Bouvier, in whose possession it now is.

(3) Bulletin de l'Acad. Royal de Medecine, vol. IIII. p. 491. The author in order to give an accurate idea of the disposition of the fibrous bands, presented to the members of the academy the two hands carefully dissected.

tion,—he therefore returned to Paris and was received at St. Louis, on the 1st November, 1843. The fistula, situated as already stated, was ten lines in length, and four lines in breadth. All the urine escaped through the opening, at which the mucous membrane of the urethra could be perceived; a sound passed in easily, the canal being free from stricture. An antisyphilitic treatment was prescribed, and twenty days after, urethroplasty was performed, the portion of skin being taken from the scrotum; it was however, unsuccessful, the threads having divided the skin two days after, and the flap separated. The operation was repeated and the flap was then taken from the integuments covering the left groin; four or five days after, the thread divided the skin, and the flap was again detached; as the union by the second intention likewise failed, it retracted and formed a small tubercle, which is still perceptible on the left side of the scrotum. But thanks to the mercurial course, the syphilitic eruption had completely disappeared, and about the end of March, 1844, a third operation was decided upon, and accomplished as follows:—the edges of the fistula were cut off in a slanting direction, so as to have a bleeding surface of about two lines in diameter; two incisions parallel to the axis of the penis were made on each side of the opening, and extended on the scrotum for about an inch and a half to two inches, so as to comprise between them acutaneous flap of about an inch to an inch and half in size. This flap completely dissected from below upwards, was placed over the fistula, its lower extremity being in contact with the upper part of the orifice, to whose circumference it was united by the interrupted suture: a middling sized sound was then introduced into the bladder, and gentle pressure was made on the flap so as to keep the parts in apposition. The symptoms of syphilis no longer existing, union was obtained in about five-sixths of the circumference of the fistula, a small opening alone remaining by which a probe could be introduced, and through which the urine flowed constantly. Dr. Jobert de Lamballe endeavoured to obliterate it by incising its edges, and uniting them by means of the twisted suture, attempts which proved altogether unsuccessful. In June, 1845, the fistulous opening still existed, an ordinary probe could easily be introduced, and when the patient made water, it flowed in a stream the size of a bristle. Attributing the non-adhesion of the edges of the wound to the existence in the system of the syphilitic virus, mercurials were again had recourse to, and at the commencement of February, its obliteration was re-attempted, and with complete success: the operation consisted in removing the surfaces of the edges of the fistula, and uniting them by two twisted sutures; the pins were left *in situ* for thirty days, and on their removal a *very* small opening alone remained, which by the progress of cicatrization and a few cauterizations with the azotate of silver, was entirely closed. 30th March.—The urine for the last week has ceased to flow through the fistula; the corpora cavernosa and the glans penis have assumed the normal size and form; the skin covering the penis presents the cicatrices of the flap with the circumference of the fistulous opening; the penis is in its natural position, and erection takes place easily.

On Accidental Retraction of the Limbs. By Dr. Morel Lavallée.—*Pathology* (continued). Having thus described the state of the fibrous tissues which bend the fingers and keep them motionless in this abnormal position, that of the sub-cutaneous bands which produce a contrary effect remains to be examined. The following case, recorded by Dr. Bouvier, who performed the *post-mortem* examination, will give a correct idea of this species of lesion. "A little girl, six years old, was received at the Children's Hospital in the wards of Dr. Baudelocque, presenting these symptoms: right hand forcibly extended; indicator so fixed that it could not be bent by the greatest effort of the patient; a thin, strong band extended from the base of this finger to the lower part of the fore-arm, passing under the carpal ligament, which formed a marked depression, *especially at the wrist*; the direction of this band, completely isolated from the surrounding parts, and the absence of a fibrous layer on the back of the hand, similar to the palmar aponeurosis, caused Dr. Bouvier and the persons present to conclude that it was perhaps produced by the tendon of the extensor muscle of the indicator. While undecided as to the mode of treatment, whether an apparatus should be applied so as to elongate the muscle supposed to be affected, or the tendon should be divided, the child then convalescent from rubeola, was seized with violent dysentery, and died on the fourth day after entering the hospital. On dissection the lesions discovered were: the hand presented the two varieties of retraction, the indicator being forcibly extended, and the medius permanently bent. The former, which alone had been remarked during life, was produced, as well as the latter, by a band developed in the fibrous envelope of the part. In fact, the fibrous band, which was mistaken for the tendon of the extensor of the index finger, was nothing more than a considerable hypertrophy of the aponeurosis of the fore-arm, and of the prolongation which it sends to the back of the hand. Firmly fixed to the radius, conjointly with the anti-brachial aponeurosis, of which it really was a portion, its sides were continuous with the superficial layers of the annular ligament of the carpus, and the thin aponeurosis which covers the back of the hand. On the first phalanx of the indicator, it was closely united with the tendons of the extensor muscles, but was separate every where else, proving that the division of this band by the sub-cutaneous method, as employed in the section of the tendo Achillis, would have been crowned wih success, and that the movements of the finger would have been restored, as the tendons were in no respect affected. But in such cases, how can the retraction be recognized from that produced by the muscles? The following sign may perhaps render this distinction easy; viz., the superficial position of the aponeurotic band at the wrist, because the tendons kept firmly fixed by the annular ligament of the carpus, cannot project so much when the disease is produced by muscular retraction. The fibrous band which acted on the medius was evidently a portion of the palmar, whose terminal bands were strengthened by fibres developed in the surrounding cellular tissue. A remarkable peculiarity likewise existed in the present instance; the tendons of two flexor muscles grew thinner and thinner on reaching the first phalanx, and ended in the fibrous tissue which covers this bone, and which, with the band proceeding from the palmar aponeurosis, forms the sheath of the tendon. Sub-cutaneous division, though it would permit the fingers to be straightened, still would not have restored its movements, as the two tendons would inevitably have been divided. Perhaps this circumstance which constitutes a counter-indication to the operation proposed and performed by Dupuytren, may be recognized during the life of the patient, inasmuch as the second phalanx cannot be bent, which may be done when the tendons retain their normal condition."(*)

There exists no anatomical description of the retraction of the plantar aponeurosis, but its normal disposition being the same as that of the palmar aponeurosis, in all probability its lesions are likewise to a certain extent, analogous. Science is likewise equally in the dark as to the state of the fibrous envelopes of the other regions of the body, for though several have been found to be contracted on the dead body, the modifications their texture has experienced, have never been accurately described. Finally, it may be remarked, that the retraction of the muscles and albuginous tissues complicate generally, if not always, each other, whether their development takes place simultaneously or successively.

The following case is a curious example of the participation of all these tissues in the production of this affection,—aponeurosis, muscles, and even the capsule of the articulation (one side of which is notably shortened), all are retracted. Dr. Richet, M.D., Surgeon to the *Bureau Central, Prosecteur* at the Faculty, who dissected the limb, described its lesions thus:—"On the body of a woman, 69 years old, I found a retraction of the right inferior extremity, which had bent to a considerable degree; the thigh on the pelvis, a rotation of the limb inwards, and adduction carried to such an extent that it crossed its fellow. At first sight, and on examining the parts superficially, I thought it was produced by a dislocation of the thigh upwards and outwards, but I sought in vain for the head of the femur in the fossa iliaca externa, besides which, on measuring the extremity I found it to be as long as its fellow. This led me to examine carefully a large band situated on the outer side of the hip, and extending from the anterior superior process of the spine of the ilium (to which it was united for about one and half inch to two inches), to the anterior portion of the trochanter major evidently below the spot where the tuberosity is united to the shaft of the bone. This band raised the skin considerably, whenever the limb was carried in abduction or extended, and still more so, if at the same time it was turned from within outwards. No other band could be felt under the integuments, however forced the position might be. I felt therefore convinced that the retraction of the limb was owing to the presence of this large aponeurotic band, belonging to the fascia lata, which receives in a fold of its posterior edge, several of the fibres of the gluteus maximus which are attached to it. This band is inserted superiorly to the anterior third of the external portion of the spine of the ilium, inferiorly to the femur, below the trochanter major, and anteriorly it is continuous with the fascia lata, which envelopes the anterior and internal portion of the pelvic extremity. I ascertained, by a careful dissection, in which Dr. Desprez assisted me, the correctness of what I advanced. Our opinions, however, differed slightly; I thought that the retraction was produced by this band alone, whilst Dr. D. considered it to be owing to the retraction of all the fibrous tissues of the anterior part of the thigh, and his opinion proved to be correct. To ascertain the precise state of the parts, I divided the band carefully, and I found it very dense and firm, and in its centre, about three lines in thickness, that is to say, at least five or six times greater than that of the opposite side. Its tissue was compact, and crossed each other in all directions, and seemed more highly developed than the albuginous tissue in its normal state; finally, and this *fact is important*, on examining it closely and attentively, one or two drops of a sero-sanguinolent liquid might be seen exuding from the cut surface, and a few minute vessels could be perceived in the thickness of the large fibrous cord. After its division, the inward rotary movement disappeared, but the flexion continued, showing that it was not the cause of the deformity of the limb. I therefore dissected carefully the subjacent parts, and I found the tendon of the psoas and iliacus stretched on the femur and os ilium like a bow-string. I thought that I had discovered the cause of the flexion, and, consequently, I divided the muscle, and detached it from above downwards; this done, the limb could be extended almost entirely, but as it still remained slightly bent, and drawn inwards, I sought to discover to what cause this could be attributed. The adductors next presented themselves, but they were not very firmly retracted, since the least efforts sufficed to overcome their resistance; finally, there remained only the fibrous envelope of the capsule of the articulation, and on examining it, I found all its anterior portion, and especially the anterior band which, from the internal and superior part of the acetabulum extends to the inferior and posterior portion of the base of the neck of the femur, was very much stretched when the limb was extended; I divided the capsule layer by layer with the greatest care, and ere it was opened, the limb could be completely extended. It was natural to endeavour to discover the primary cause of this retraction. I therefore sought for it in the muscles surrounding the articulation, but they presented the usual suppleness and normal firmness; there was nothing to show that they had been affected previously; they were only, as is generally the case in old

(*) Bulletin de l'Acad. Royal de Med. Vol. I. p. 422.

women, and as they were on the opposite side, somewhat softer. I next examined the bones, to see if they offered any lesion by which it could be explained, but they were all perfectly sound. It may be remarked that I examined all the vertebræ, the sacro-coxal articulations, &c. All that remained was the femoro-tibial articulation which might have been the seat of chronic coxalgia: this however could not be admitted, since the bones, cartilages, synovial membrane, in short all the constituent parts of the articulation were found to be quite healthy, and all the movements of the head of the femur in the acetabulum, could be performed without difficulty, so much so, that any one on seeing the articulation alone, would never have imagined that it had been in a state of semi-dislocation caused by the forced flexion owing to the retraction of the parts just described. I had preserved the psoas and its tendon, the capsule of the articulation and the fibrous band, in order to examine them after maceration, but unfortunately the vase in which I placed them was broken, and its contents by mistake thrown away."

"*Reflections.*—After having, as I have just stated, sought fruitlessly in the bones, in the articulations, in the muscles, in a word in all the tissues near the thigh, for a lesion which could have given rise as is frequently the case, to the tendinous retraction above described, I found myself under the necessity of seeking elsewhere the cause of this phenomenon. Now it is well known that fibrous tissues, whose vitality is not very great, are seldom the seat of diseases peculiar to them, and which are developed primitively in their substance; it is from this fact, founded on numerous *post-mortem* examinations that I concluded that white swelling *never* commenced in the ligaments or fibrous capsules which are affected consecutively. Must it therefore be supposed that I mean that the fibrous tissues may not be attacked with diseases presenting pathognomonic phenomena? Doubtlessly not; all that I mean to say is, that as they are not very vascular, and are of very obscure vitality, are acted upon very slowly, and receive no nerves of their own, their diseases must differ widely from those which attack parts rich in vessels and nerves, and whose irritability is considerable. But the *essence* of these diseases is far from being well known, and the retraction and hypertrophy with thickening of the albuginous tissue, appears to me to be two of the most constant modes by which the morbific causes manifest themselves. Applying therefore this method of reasoning to the present case, I think that the retraction with which the fibrous tissues and the fascia lata, the orbicular capsule and the tendon of the psoas and iliacus, were affected, was the result of a disease peculiar to the fibrous tissues, as yet but little known, of whose nature we are ignorant, especially as it was impossible in the present instance to obtain any information as to the mode in which it had developed itself. I know it might be said with Professor Gerdy that inflammation of the albuginous tissue had existed, but in this hypothesis it is necessary to prove—first, that they had been really inflamed, which does not seem possible, if we give to the term inflammation the signification usually attached to it—secondly, it is necessary to discover and shew the mode in which the cause acted; by whose influence all the fibrous tissues situated at the antero-internal part of the thigh were inflamed without the surrounding soft parts (which are so vascular) participating in the inflammation; and in admitting this opinion, we are obliged to confess that it is a phlegmasia of a peculiar nature, in no respects similar to those which affect the other tissues of the economy."

A few remarks may be made on the reflections with which the author terminates this interesting case. He refuses to admit the action of an inflammatory cause, as he does not think it possible that all the fibrous tissues of the antero-internal part of the thigh could be affected without the very vascular surrounding tissues being likewise attacked. But could not the latter have been the seat of phlegmasia, which terminating by resolution, had left no traces whatever of its existence? To admit the influence of a phlegmasial cause, is it necessary that it should have acted upon *all* the fibrous tissues situated in the groin? Might it not have been limited to the hypertrophied aponeurosis, under whose influence retraction had taken place? And in this supposition, ought not the sides of the capsule of the articulations and the shortened muscles diminish in length by the molecular action of nutrition, so as to accommodate themselves to the space they were then destined to fill? Finally, whether it be that the aponeurosis was affected by the variety of inflammation described by Professor Gerdy—(and the vascularity of the band favours this supposition)—or was a simple *cryptogamous* hypertrophy, as sometimes seen in the palmar aponeurosis, it is the fibrous band which seems to have been alone a primary seat, and the active cause of the retraction. It drew and kept the thigh bent. As to the other tissues, the retraction was passive, and consecutive in the same way as the muscles of the hand after the retraction of the palmar aponeurosis, &c. The principal lesion presented by the muscles and capsule, was a shortening—whereas the aponeurosis offered all the signs of a highly developed active retraction. Finally this observation may be classed under the same head as many others published in this memoir.

The skin although, when quite sound, it may, after the division of the fibrous bands or tendons, recover its normal length (Dupuytren, Goyraud), yet in others, it may have an active part in the retraction, and present an inodular aspect without previous suppuration. The author witnessed a curious example of the shortening of the integuments so accurately described by Dr. Malgaigne.—It was a retraction of the fingers. The skin had so shrunk, and adhered so closely to the palmar aponeurosis, that it was with the greatest difficulty that the tenatome could be passed between the two. The retraction of the ligaments must not be omitted, as this lesion has been demonstrated by *post mortem* examinations and by surgical operations. It has frequently happened that after having divided all the retracted tendons of the ham, the surgeon is obliged, in order to straighten the limb, to cut the lateral ligaments. The retraction of these fibrous bands is, without a doubt, in general consecutive; but situated, as they are, in the direction of flexion in ginglymi, they may, when shortened, contribute to produce this affection. The same remarks are applicable to the sides of the capsule—to the tendons and their sheaths. However, until pathological anatomy has cleared up all doubts on this subject, we can have but an imperfect idea of this lesion, and the author expressed his regret that such was the case, before Dr. Richet's case came to the support of his opinion.

GARLAND DE BEAUMONT, D.M.P.L., & S., &c.
Honorary Physician to the Spanish Embassy.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M. D.

On the effect of uva ursi in ischuria.—A man eighty-one years of age, affected with enlargement of the prostate gland, and who, in consequence of irregular living, had been often attacked by ischuria, was again seized by this complaint in the middle of May. A surgeon who had been called in to catheterize him, in attempting the operation, forced a false passage through the walls of the urethra, and gave rise to exceedingly serious hemorrhage. When the writer of this paper was consulted, he found the patient in a state of low inflammation; the abdomen was tender and very painful, and sickness at the stomach. In such a state of things no catheter could be introduced. The patient was bled and put into a warm bath; clysters, fomentations, etc., remained without producing any beneficial effect, so that the writer had no resource, but to puncture the bladder above the symphysis pubis, by which means a great quantity of urine was discharged, and the patient relieved. On the second day symptoms of subacute peritonitis made their appearance, which induced the author to remove the canula. Under the use of appropriate remedies these were soon removed. The catheter could now be passed into the bladder, so that there was not occasion for the use of the trocar any longer. By cauterization with nitrate of silver, the wound over the ossa pubis was closed within a month, but the bladder still refused to expel the urine, although lukewarm water had been injected into that organ, and the patient himself subjected to the influence of ergot of rye and Jesuit's bark. As a last resource, the writer prescribed for him a mixture of uva ursi as follows:—

Px. Fol. uvæ ursi, ʒj.
℞. Aq. Fervent, q. s. ut colentur, ℥iv.
Adde—
Ext. Cardui Benedicti, ʒj.
Liq. Ammon. anis, ʒj.
Tr. Rhei aquosæ, ʒvij. M.

Two days after commencing this mixture his urine flowed, and still continues to flow, *per urethram*, without any artificial aid.—*Ritter of Rottenburg, in Heidelberg Annalen.*

On the use of vin. sem. colchic. opiatum against rheumatism.—The author sets out by giving to Eisenmann the merit of discovering that combination with opium increases the power of colchicum. The writer has ordered Eisenmann's *vinum colchici opiatum* for persons of different ages and sex; he has prescribed it even during menstruation and pregnancy, and never found any injury to arise from it. Its use, however, is improper in violent feverish excitement until the irritation be subdued; also in affections of the respiratory or abdominal organs. Dr. Hauff professes to have produced the most astonishing results with this remedy, particularly in the treatment of the rheumatic tooth-ache of the female sex, whether the gums were affected or not. He also used it with great success against rheumatic headache, quinsy, lumbago, acute articular rheumatism; but it seems to have wrought no good effect in his hands in chronic rheumatism. This, however, he found to yield soon to quinine. The Dr. contradicts the assertion of Eisenmann, that this remedy ceases to display any anti-rheumatic effect as soon as it has caused diarrhea, and asserts that it has never proved so successful in his hands as when it produced either an abundant diuresis or profuse serous diarrhea. This drug sometimes induces vomiting, vertigo, and dimness of sight. Its usual dose for adults and sensitive females, is 15 drops three times a day; for grown men, five and twenty drops thrice daily.—*Dr. Hauff of Kirchheim, in Wurtemb. Corresp. blatt.*

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN SCIENCE.

(The following are the only articles of interest in the last number but one of the *Lancet*.)

ANEURISMAL TUMOUR OF BONE.—Mr. Topham mentions the case of a young man, who had an enlargement occupying the situation of the internal condyle of the right femur, which presented a hard resisting surface to the hand, except at one part which was less resistant, and was the only place where pain was felt on pressure. As a distinct pulsation was perceptible, synchronous with each beat of the femoral artery, which was arrested by compression of that vessel, while, at the same time, the tumour diminished somewhat in size, M. Nelaton, under whose care the patient was, determined to tie the femoral artery, which he did in the middle portion of its course, with the effect of causing the immediate, but temporary cessation of pulsation in the morbid structure. It returned, however, in the course of a week, and the operation was consequently unsuccessful.

TIC-DOULOUREUX.—Mr. M'Veagh has narrated several cases of severe face-ache, apparently dependant on derangement of the chylopoietic viscera, which were cured by remedies tending to remove their cause. He has termed them instances of tic-douloureux, but, in our opinion, erroneously. A case of the genuine disease does not seem to have fallen under his notice, and he has consequently been led to confound with it diseases presenting some points only of similarity.

REFLEX ACTION.—Mr. Barlow mentions a case of paralysis from spinal disease, in which, although the lower extremities were utterly powerless, the

application of stimuli induced powerful contraction of their muscles, over which volition had no power.

Laryngismus stridulus.—Mr. Meade attended a case of laryngismus stridulus, occurring in an infant, after chicken-pock, with disorder of the primæ viæ, in which a cure was effected by means of purgatives, and the exhibition of chalybeates. The effect of purgatives was most marked; when the bowels were freely opened, the spasmodic attacks were always milder, and if their use were intermitted for a day, and the bowels were not relieved, the fits of suffocation were much more severe. Another case, occurring in the same family, in which the bowels were naturally much relaxed, terminated fatally very suddenly. The body was examined after death, but there was not found in the chest nor abdomen sufficient cause to account for the fatal termination. The head was not examined, the parents objecting thereto. Mr. Meade observes, that the disease with which spasm of the glottis (laryngismus stridulus) has been chiefly confounded, is spasmodic laryngitis, or spasmodic croup, as it is commonly called. The two diseases principally differ in the following points:—1st, spasm of the glottis is almost exclusively met with in young infants, from the time of birth up to twelve or eighteen months of age: spasmodic croup, on the contrary, is extremely rare in infants under a twelvemonth old. 2ndly, In spasm of the glottis there is neither coryza nor any febrile disturbance, while spasmodic laryngitis is always preceded and accompanied by some catarrhal symptoms and slight feverishness. 3rdly, The first attack of spasm of the glottis may come on either in the night or day, and a child has been known to have more than twenty fits in the course of the same day; spasmodic croup, however, always attacks for the first time at night, and the child will never have more than five or six paroxysms of difficult breathing during the whole attack. 4thly, In spasm of the glottis there is no cough, and during each fit there are seldom more than one or two stridulous inspirations; while in spasmodic croup there is always a hoarse cough, and the difficult and noisy breathing continues for some time. 5thly, In spasm of the glottis, convulsions generally come on after the disease has continued for some time, and also carpo-pedal contractions. Convulsions are very rare, on the contrary, in spasmodic croup, and the contractions of the limbs have never (as far as Mr. Meade knows) been observed. 6thly, Spasm of the glottis is almost always a chronic disease, while spasmodic croup is essentially acute. Spasm of the glottis is an occasional symptom of chronic hydrocephalus, and when it occurs, renders the prognosis unfavorable. It is considered to consist essentially in a narrowing or a complete closure of the rima glottidis, produced either by true spasm of the muscles closing the glottis, or by paralysis of those whose office it is to open it. It is essentially a nervous affection, arising from various sources of irritation, either direct or reflected, such as scrofulous enlargement of the bronchial and cervical glands; hypertrophy of the thymus gland; irritation of the gums from teething; disorders of the alimentary canal, cerebral disease, &c. With respect to the treatment, it must be adapted to meet the nature of the exciting cause. As the disease generally occurs in delicate and scrofulous infants, the chief indication must be to strengthen the general health, and to remove any evident causes of irritation. If the child be much under a year old, and has been weaned, a wet-nurse should be immediately procured. Should the mother be delicate, and be suckling her child, a strong healthy nurse should be obtained in her place. If evident signs of scrofula be present, and the locality be damp and cold, change of air to a more salubrious situation should be recommended. Besides these general rules, all apparent sources of irritation, whether in the alimentary canal, gums, or head, should, if possible, be removed by appropriate remedies.

Dislocations and fractures.—Under this title, Mr. Gurney describes several cases which have occurred to him in practice. The first is one which he describes as dislocation of the thigh downwards, the man being able to walk about after the accident, but lamely, and in pain. The affected limb was more than an inch longer than the other; the toe was slightly everted, and could be turned in or out readily, but the latter more so than the opposite foot; there was great swelling of the buttock, and considerable effusion over the trochanter major. When sitting, the left knee projected considerably, and flexion on the pelvis beyond the sitting posture caused great pain, and could not be borne, while the other knee could be approximated to the mouth easily. When standing on the injured limb, the opposite heel could not be brought to touch the ground by more than an inch, and when standing on the sound limb, the injured one was bent at the knee. The trochanter major was at more than an inch greater distance from the crista of the ilium, and projecting more both forwards and laterally, than on the sound side; and Mr. Gurney thought he could feel the head of the bone by pressing behind the trochanter, and a little above it, doing which gave the patient violent pain. As when the patient was sitting with the knees approximated, the injured limb was considerably longer than the other, Mr. Gurney was of opinion, that the head of the bone must have been dislocated immediately under the acetabulum, and in flexion of the thigh, inclined forwards, and not behind it. A difference of opinion existed in this case, with respect to there being a dislocation; nevertheless, attempts at reduction were made, and were apparently successful. Both limbs were afterwards of the same length, and the man was able to go up stairs, with the injured limb foremost, which previously he could not do.—Another case of dislocation, behind and below the acetabulum, is mentioned by Mr. Gurney, in which a similar difference of opinion existed, as to the nature of the accident, and in which the employment of the usual efforts at reduction were crowned with success. Three cases of dislocation of the clavicle under the sternum are next mentioned. These accidents arose from the patients being thrown in wrestling on the back part of the shoulder; the symptoms were difficult respiration, and violent pain in the part, with depression of the sternal end of the clavicle, and in the sternum. The reduction was effected by depressing the sternal end with the thumb, while the fingers introduced beneath the clavicle were pulling it outwards, and elevating it, the shoulder being kept back, at the same time, with the other hand. Reduction was easily accomplished in all three cases, and in a few days the men were able to work. (We confess ourselves unable from Mr. Gurney's description, to comprehend either the nature of the accident, or the mode of reduction.) Mr. Gurney treats fracture of the clavicle in the following manner:—he elevates the shoulder of the affected side, by putting the hand under the elbow; he then takes a handkerchief doubled, and passes it under the elbow, tying it over the opposite shoulder as tightly as possible; he also applies an adhesive plaster, on a dossil of lint, over the fracture, suspending the hand by another handkerchief around the neck. The clavicle is in apposition as soon as the shoulder is elevated, and the handkerchief is kept from slipping, either before or behind the elbow, by stitching it through in both places. This is to be worn for three weeks, and replaced occasionally; the only thing complained of is the pressure on the opposite shoulder, which may require a little soft wadding under the handkerchief.

The operation of version.—Mr. Dalton narrates a case of arm presentation with the shoulder in the perinæum, and the spine towards the abdomen, in which, from the impossibility of controlling the uterine contractions, and consequently from not being able to introduce the hand, he was necessitated to adopt a medium plan, and convert the case into a breech presentation. He passed the index and middle fingers of the right hand to the occipital protuberance of the child, and found he could raise the head upwards and towards the left iliac fossa, in which position he succeeded in maintaining it during a pain, the subsidence of which gave him an opportunity to introduce the index finger of the left hand, which, resting against the lower cervical or upper dorsal vertebræ, served to prevent the child receding, as well as to form a kind of fulcrum, by which the evolution of the child was further facilitated. He then pushed the head of the child still higher with the fingers of the right hand, whilst, with that of the left, he afforded firm support to the trunk during the pains, and during the remission he passed successive portions of the spinal column towards the left ilium of the mother, whose position, on the left side favoured the operation, by aiding the descent of the child by its own gravity to the left ilium, until the breech presented, which was immediately followed by uterine contractions, and the expulsion of the child. The placenta speedily followed, and the woman recovered without a bad symptom.

Induction of premature labour.—Mr. Greenhalgh detailed, at a meeting of the Westminster Medical Society, the case of a lady upon whom premature labour was several times induced, in consequence of ovarian disease. On the two last instances, the child born at the seventh month survived.

Ligature as a means of cure in fistula ani.—Mr. Barton, in a communication as to the relative value of the ligature and the knife in the treatment of fistula in ano, briefly mentions his own case, and says, he was subjected to the application of the ligature on two occasions, his sufferings being very severe, great irritation being set up, and additional sinuses formed. He was afterwards cut, and finally obtained a cure, with comparatively little pain.

Hydatids of the liver.—An intemperate man, thirty-two years of age, was admitted into the Birmingham Hospital with enlargement of the liver, which descended as low as the crest of the ilium of the right side, bulged the ribs very considerably behind, and was very prominent in the right hypochondrium; in the middle line, it did not descend below the umbilicus; there was also an obscure sense of fluctuation, and a dull continued pain. The countenance was expressive of great anxiety, and there was considerable emaciation, and other indications of ill-health. The man died after being in the hospital about six weeks, having previously suffered from hepatic peritonitis. The liver, on examination after death, was found to weigh fifteen pounds. the increase being confined to the right lobe, which was converted into a cyst, lined with a false membrane of loose structure, and containing some pints of a straw-colored fluid, in which floated a large number of distinct hydatids, varying in size from a walnut to a pea. The liver was firmly adherent by bands to the abdominal parietes.

Professor Brande and Professor Graham take the places of Examiners in Chemistry to the University of London, vacated by the lamented death of Professor Daniell.

Apothecaries' Hall.—Gentlemen received licentiates on the 10th April, 1845:—James Lewis; Robert Appleton; Henry Edward Dullen; William Tiffin Iliff; Nathan Kennicott; James Wallace; David Simpson Penrice; Edward Martin.

NOTICES TO CORRESPONDENTS.

B. *surely cannot be a constant reader. We are precise in furnishing the lists. When none are given, no gentlemen have passed.*

Medicus.—*The clauses of the Irish Apothecaries' Act are left by the Bill just as they were, except that the Company is quietly superseded by the creation of arrangements that profess to make it needless. Sir James Graham, however, has consented to keep up the importance of the Hall as a licensing body, and will, therefore, introduce some alterations not yet known to us. In any case, it is fair to presume that in this day of medical tolerance no restrictions by one class of medical men will be allowed to be laid on the fair and reasonable practice of another.*

A Dublin Subscriber, *if the Bill pass this session, cannot register as a physician, unless he be a physician at the end of the session.*

An old Student.—*All gentlemen will be eligible candidates for our "Student's Prizes" who, at the date of sending in their "reports" are bonâ fide medical students. In answer to several other gentlemen writing on this subject, we hope in a fortnight to publish the names of the arbitrators.*

J. H's *statements on Foreign diplomas is a defence*

of what is indefensible. English money should be better employed, even if the diplomas are valid and well earned. Anonymous correspondence on contested facts is also quite useless.

W. P. S. *has our best thanks. The paper shall appear.*

Dr. Davis, (of Manorhamilton,) *sends us an authenticated statement, that in the neighbourhood of Londonderry, several ladies have gone to bed quite well, and in the morning have been found in a complete state of insanity. More than six cases have occurred in a rural district within a circle of twenty miles. The mania is uncontrollably violent, and characterized by an extreme anxiety for the nudity of nature. Our correspondent speaks of the visitation as an epidemic, like some of those that are recorded as taking place in the sixteenth and seventeenth century in Germany and France.*

Medical Times' Defence Fund.

We have received this week subscriptions from,

	£	s.	d.
Dr. Warenne, (Hull)	1	1	0
Mr. Ward, (Manchester)	1	5	0
M.D. (Londinensis)	2	2	0

We beg to repeat our request that gentlemen proposing to subscribe will kindly withhold their contributions till the result of the enquiry be known. We have to acknowledge several very obliging communications on this subject, and to present our very best thanks to the writers.

A Constant Subscriber.—*There was no right to what was a clear injustice. The party should be summoned before a Court of Requests, if practicable, or his ill conduct submitted to the magistrates in Quarter-Sessions. But an attorney should be consulted.*

G. B. W.—*Our correspondent should act on the value he may attribute to the* sanction *given by the Society to his qualifications. If the bill pass, the license will not be necessary; but among* medical men, *it of course will always tell as regards status. In W.'s case we should ask for the license.*

A Constant Reader.—*Dr. Rigby's mode is the ordinary one. There are also glass tubes made which answer the purpose extremely well.*

Mr. R. Tewksbury.—*We think compliance with the request inconsistent with our public duty. The report would be mutilated, and the facts falsely given, if the omission were made.*

Mr. Spence.—*The first request will be attended to. The second is best answered by our Students' number for October last. In special cases, no answer can be given, except by Mr. Balfour, who should be addressed on the subject.*

Mr. Kinder.—*The terms of the Pharmaceutical Society may be known by writing to Mr. Smith, the Secretary, in Bloomsbury-square. We do not write private answers to such questions as our correspondent proposes.*

Henry H.—*Indelible, except by setting up ulceration—a remedy worse than the disease.*

E.—"*Extra Licentiates*" *will be allowed to register as* "*Physicians.*" *So also will all M. D.'s, graduates of a British university.*

Mr. Stopford Taylor, of Sheffield, *complains to us, in strong terms, of the injustice done to him by a contemporary, somewhat inconsiderate about the repute of the profession, and on that liberal principle which handsomely exposes himself to the same treatment he gives to others. We will next week give a summary of the evidence on the trial, with our correspondent's letter.*

A Reformer.—*The evil will work its own cure.*

A Surgeon, *need have no fear. The National Association is rapidly enrolling members, and the whole battery of calumny and wounded vanity has not induced two members to withdraw from the Association.*

A Pathologist *is thanked.*

Numerous communications have been received. Those accepted will be named in an early number.

J. E. London, *should have authenticated his note with his name.*

Dr. Borrett.—*The Pharmaceutical number dated May 31, is the June number.*

Mr. Toulmin *is thanked for his obliging hints, which impress and strengthen our own convictions. They will not be overlooked.*

THE MEDICAL TIMES.

SATURDAY, APRIL 26TH, 1845.

> With desperate sorrow wild, the affrighted man
> Thrice sigh'd; thrice struck his breast, and thus began.—
> "Sad was the hour, and luckless was the day,
> When first from Schiras' walls I bent my way."
>
> COLLINS.

The Council of Incapables, sitting in Lincoln's-Inn-Fields, and whose governmental imbecilities have roused more discontent, dissention, and ill feeling throughout a learned profession than any assemblage of persons that ever existed, are evidencing still further how ill they understood their position, by diligently hawking about for signatures a very formal, and, in a small way, a rather ingenious declaration in favour of their corporate ineptitudes. The very *artfulness*, however, with which its terms are couched is the strongest possible proof of the folly of its concoctors. Like many to whom nature has sparingly extended her mental endowments, they fancy that the gross blunders of folly may be cured by the half-cunning expedients of trickery, and in this foolish spirit have prepared a document, which, appearing to utter nothing but truisms, may seduce that appearance of support which, in the House of Commons, may without much violence be represented as a certificate to their good behaviour. Poor people! And this is their rock of defence in the extremity of their peril! Alas! their very protection is the exponent of their weakness and guarantee of their ruin. Their appeal to their members is the acknowledgment that the latters' feelings are the criteria of the quality of the formers' government: and tried by this touchstone, how complete will be their condemnation? All not with them in this moment of crisis it may be fairly presumed are against them; and whom have they with them? Some of the most distinguished of the *Fellows* have, to our knowledge, refused to sign: and the thousands of their outraged members would sign no document for them, but the one that called for the corporate annihilation they have so well earned. Whom, then, have they? Beyond a few gentlemen, misled by the vagueness of the statement—and who, in many cases, will doubtless recall their signatures when they learn the use they will be put to—the College policy will be propped up by nothing better, than the names of some unconsidered "*Fellows*," whose unwarranted elevation has been the very thing that has been universally protested against. The "*Fellows*" *declare* to their own excellence! The great grievance of the College come forward unblushingly to say—"We are no grievance. Instead of a grievance to surgeons and surgery, we are actually their best aids and supporters. We are really not nuisances—as everybody says—but very excellent 'Fellows,' whose uprise by others injury, will do surgery a wonderful deal of good. The charter is a splendid invention." And this is the last great move of the Council against the virtual extinction which now lies so plainly on the cards! The poet says well

> Nil habet infelix paupertas durius in se,
> Quam quod ridiculos homines facit.

and the poverty of mental resources in the Council must have been great indeed which could have induced them, thus unmercifully, to offer up their "Fellows,"

> To bitter scorn, a sacrifice,
> And grinning infamy!

We beg the "Fellows," thus disgracefully used and placed before their brethren in so odious a light, to reconsider the step they have been cajoled or coerced to take. Its indelicacy is shocking. It is as if, after being dragged through the horse-pond of professional unpopularity, they were now hung over it by their friendly persecutors, to dry! Out of regard for the decency and good odour of our common profession, we beseech them not to be wheedled by the Council into this indecent exposure of themselves. It is all very well to be "pures"—but to be *exhibited* by their patrons "in *puris* naturalibus." "Ay, there's the rub!" The "Fellows," so offending against modesty, would have their flagitious persons brought before our moral Police Court—their names published in our *Hue and Cry*—and fifty to one if they would ever again be admitted to decent society. No! It cannot be, that after this fair warning, the "Brodie Declaration," though so many months under incubation, will ever be hatched. The procedure is too dangerous.

The Council's pursuance, just now, of resolutions at once foolish and desperate, will be the less to be wondered at, if it be true, as said, that the "friend at court," who sustained for a while their insane obstinacy, is beginning to understand his men, and to be acquiring some little suspicion that he has been "hocussed." In the House, on Tuesday, Sir James Graham announced that he proposed, when going into Committee on Friday—this day—to state certain alterations which he proposed to introduce into the Bill, and the conference between him and the National Association leads to the very probable conjecture, that the College is menaced by a movement which will tell rather disadvantageously either on their *funds* or charter. A large alteration in the Council, or a new Incorporation is inevitable; and Sir James Graham has virtually acknowledged, that if he cannot bring the College rulers to reason, he will not hesitate to adopt the alternative.

In this resolve, he will have the almost unanimous support of the press. The great conservative organ, the *Times*, supported the maintainance of the College while a ray of hope shone that its rulers would do something like right to their members, but has latterly repudiated their impolicies as suicidal, and joined in the *general*, the *now* almost *universal*, cry—"Let there be a new Incorporation." The *Chronicle*, we see, by an article which appeared on Tuesday, is slowly reconciling itself to a similar necessity, and there can be no doubt that the worst effect of the recent ill-judged manifesto has been to estrange from the Council all those who, wishing the College well, did not yet despair of a just and satisfactory settlement of the deplorable strife they had so unwisely caused. Our readers will peruse the following concluding observations from the great Whig organ with scarcely less pleasure than ourselves :—

"We are the less able, also, to understand the *cui bono* of Mr. Wakley's motion at this late hour of the day, when we remember that Sir J. Graham has announced his intention of introducing several important alterations on going into committee with his new bill. It is matter of well-known fact, that of the countless petitions and memorials that have reached the Government and House of Commons on the subject of medical reform, not one has signified approval of the charter, and that nearly all have condemned it in terms the most decisive. While this circumstance establishes our conclusion that, with condemnation so universal, parliamentary inquiry is a ceremony as useless as it *is* expensive and *may* be mischievous, it suggests a hope that the Home Secretary's concessions are not to exclude the only boon with the remotest chance of conciliating the support of the profes-

sion. We are strengthened in this opinion by a conference between him and a deputation from the National Association of General Practitioners, the details of which we find in the *Medical Times*. It would thence appear that Sir JAMES GRAHAM sees but two courses before him—to arrange the differences between the council and their members, or to give the latter a new college. In one way or another, therefore, something will be very shortly done with this master grievance of the English profession, if no committees of inquiry interpose their "slow length." For ourselves, we repeat the expression of our old preference to the plan of making the College of Surgeons the collegiate home of the surgical practitioners of England; but we cannot conceal longer our fear that the insensate obstinacy and bigotry of *caste* of the council must make impossible any thing like a cordial understanding between themselves and their ill-treated members. If, as the organ of the general practitioner we have already quoted further tells us, the Society of Apothecaries, with a disinterestedness rare in corporate annals, have agreed to relinquish their medical functions to facilitate any better medical organization of the English practitioners that Government may propose, fate has placed in the hands of the Home Secretary a magnificent opportunity for satisfactorily adjusting the whole profession, especially in England. The ruling bodies of the Colleges of Physicians and Surgeons persist in considering their institutions private clubs, and as private clubs are not the establishments with which so numerous a body as the medical profession should be connected, they should be left exactly that amount of public patronage their own unaided attractions would freely draw to them, and no more. If the College of Physicians be for a select set of consulting physicians, and the College of Surgeons for an equally select band of consulting "pures," let those colleges *live* on those they *live for*. The profession the State wants (the doctors of the army and navy)—the profession the public wants (the doctors of the union, of the rural district, of the village, town and city)—these gentlemen, constituting the twenty-five thousand medical men of Great Britain and Ireland, are not select "pures," or select "physicians," ought not to support the private clubs of select "pures" or select "physicians," and might, therefore, at the present juncture, not unwisely have an *alma mater* presented to them by Government, which, instead of the attributes of small corporate guilds, would give them those of a truly national institution. To this consummation the exclusiveness and narrow-mindedness of the Colleges of Physicians and Surgeons as much tend, as does the handsome disinterestedness of the Society of Apothecaries; and we will not hastily believe that so worthy a solution of the vexed problem of medical reform will be rejected by any statesman—be that statesman even SIR JAMES GRAHAM—at a moment when it is at once as practicable as it is opportune and satisfactory.

Ah! surely nothing dies but something mourns!
BYRON.

The recent Assize intelligence, in the columns of our provincial contemporaries, gives a frightful account of the assassinations committed, or attempted to be committed, by poison. Mr. Taylor some time since reported, that the attempts to poison which had obtained record during the preceding two years, were not less than five hundred and forty one, and the presumption is not unwarranted, that the proportion of cases each day increases in a far higher rate than that of the population. We imagine that legislative interference cannot be much longer deferred; for our coroners' inquests are becoming so many farces—farces, in which the humour is forgotten in the doleful consideration that they are paid for considerably too dearly, and that they shield off, under their pretended performances, that duty of searching enquiry which is the public's greatest safeguard in these days of daring and venturesome criminality. The coroner, who is paid out of the county or borough rates, is counter-checked by a magistracy, who will tolerate anything less than a too large appeal to their pockets; and the consequence is, that coroners, who do not mean that their expensively procured offices shall lie unfruitful, sacrifice their inquest's *efficiency* to the country, the better to secure their *profitableness* to themselves. They hold many enquiries and discharge none properly, and what they overcharge the country for needless inquests, they save to it by dispensing with necessary testimony—thus balancing accounts—and on the whole giving the magistrates a very moderately-priced quarterly bill. The doctors are, of course, the great sufferers; for their testimony as to living symptoms and dead appearances are the heaviest items in an inquest's expenses, after those of the presiding functionary. But if the pecuniary losses of our brethren were the "be all and end all" of these *ingenious* procedures, delicacy would have silenced our tongue, and coroners, medical and non-medical, choosing medical witnesses of the reasonable results of their melancholy attendances, might live on their lapsed fees, in the shape of county rates, without our uttering one word of protest. But the thing is of public concern. When *ex.gr.*—Mr. Wakley forced a country jury to say "Natural Death" in a case wherein accidental posterior enquiry proved a death by prussic acid (the celebrated Hornsey case), he saved the country a surgeon's fee, but cost the country, it may be, many a life. Through the public press, and by a striking example, he taught each budding Belaney, each immature Tawell, how remote were the chances of detection of a prussic acid case by a coroner's jury, and removed, we know not from how many a blackened conscience, the only obstacle between the horrid wish and still more horrid perpetration. Belaney could scarcely have heard of the affair at Hornsey before he hurried to be as near it, for another, as Stepney.

One step, then, towards the diminution of poison cases must be an early reform of the coroner's court. How effect this? By introducing a system which will bring into play the very detective powers which the present system represses. The medical man now is nothing: in the new plan let him be everything. Let him rule the coroner's movements: not the coroner his. Let there be, in every district, a certain number of medical inspectors, who (in addition to other duties equally important to society) shall have the responsibility of noting every death, of inspecting every corpse, and, on due enquiry, certifying whether there be cause or not for a coroner's inquest. The expense of unnecessary inquests being thus saved, we could better afford to do full justice to those that were held. The inspector would attend with his facts—the medical man would be there with the results of his observations on the living patient or dead subject—the machinery would exist which would bring to bear every scrap of evidence that could elucidate the whole matter, and we should run no risk of medical coroners pronouncing, *ex cathedrâ*, that deaths by poisons came by nature, or any other misleading decision, which, while making money, would save time and spare trouble.

The scheme thus hastily suggested is not new. It has, we believe, been already suggested to the Home Secretary, from whom it has received a warm welcome and hearty approval. It is rumoured that it was this session to have assumed the shape of a brief ministerial bill. It has not; and why we know not. Perhaps it serves as a rod in pickle for a vacillating M. P., a patent snaffle held *in terrorem* over a restive coroner. If so, it is a sad fate for an important improvement. But there seems a dispensation in these matters. Your huge sinner has always something he can compound with to avert justice!

Another suggestion to prevent poisoning is to limit the sale of all potent poisons to medical men and druggists—none being sold without a medical man's prescription, or without distinct registration by the vender. As it is, the most common of poisons (arsenic), against the ingestion of which there are the fewest signals of alarm or caution held out to us by nature, may be had from almost any grocer—especially in rural districts—under any pretence and without any special notice. We may feel, with others, a very sensitive and timid dread of infringing the social freedom of the subject; but in the precautions we have noted, the inconvenience on the score of personal liberty, or rather lawlessness, is so insignificant that we cannot consent to weigh it, for a moment, with the social security it would give on the other side.

THE ABSURD ULTIMATUM.

The Council of the College of Surgeons, if we are to consider the manifesto recently issued in answer to the resolutions and protest transmitted to them by the Committee of the National Association, as their deliberate and final decision on the question of admission to the fellowship, would seem to have made up their minds *coute qui coute* to disown and shuffle off the great body of the members of the college. They repudiate, (such is the term which best characterizes their proceedings,) their obligations to the members, but carefully retain the manifold advantages which the College has heretofore derived from its connexion with them, and now add insult to the injuries already inflicted, by a wretched attempt at palliation for their obstinate rejection of the only fair and satisfactory mode of selection for the fellowship which, in reference to the existing members of the body, could have been adopted.

We have no intention of following them step by step throughout the fallacies of the sample of special pleading before us. For the weakness of their general propositions, they have one of two excuses to make, and perfectly are they welcome to their choice of either horn of the dilemma. It matters little whether it is to defective judgment or to the weakness of the cause, that so lame and impotent a production should have been issued from their body, or bear the official signature of their authorized organ of communication; in either case they have no right to the pre-eminence to which it is their endeavour so pertinaciously to make out a claim. But it does matter much for their individual characters as gentlemen, that the sneer with which it is insinuated, as an insurmountable objection to the adoption of the principle of seniority, that the fellowship would thereby have been profaned with "persons who have violated the laws of their country"—"professional paupers and notoriously bad character"—"puffers and venders of nostrums and secret remedies"—"the writers of indecent advertisements"—"surgeons' assistants"—"those who have connected themselves in business with chemists and druggists"—"retail shopkeepers, who expose for sale cattle drugs and perfumery"—we say it does matter much for their individual character as gentlemen, that the true import of such language should be explained.

The simple requirement of a certificate, signed by three or more surgeons of known respectability, (members of the Council in the first instance, and subsequently Fellows,) would have been sufficient

to obviate every objection from this source; and for the rest we should like to know how, if the respectability of the College is to be kept up at all, persons such as those referred to can be retained in it, whether as members or fellows.—*Provincial Medical and Surgical Journal.*

MEDICAL REFORM.

Hoc opus, hoc studium, parvi properemus, et ampli,
Si patriæ volumus, si nobis vivere cari.

To the Editor of the "Medical Times."

SIR.—In compliance with my promise, I transmit a third and final communication on medical reform.

Were the feud between the Council and members of the London College of Surgeons satisfactorily adjusted, which it will, I hope, be forthwith, there could, I imagine, be no better basis for a new code of laws, regarding Membership and Fellowship, than that on which the sister College of Edinburgh is founded;—an institution which, to its immortal honour, has done more to improve medical education than any other in the kingdom. It has especially improved the education of the general practitioner, and elevated his *status* in a high degree. That the Edinburgh College has also produced many surgeons surpassed by none in Europe—"Modern Athens" herself—London—our army and navy, at this moment, afford triumphant proof; to say nothing of the Monroes, the Bells, and the Woods of other days.

The liberal and enlightened policy of the Edinburgh Royal College of Surgeons is beyond all praise. Whilst other medical corporations have been *scheming*, by every artifice which subtlety and avarice could devise, to place gold in their coffers—or, rather, in the pockets of their officials—the Edinburgh College of Surgeons has uniformly resisted the temptation to which it has been long exposed, of taking any pecuniary advantage of its position, as a Licensing Board whose diploma has been eagerly desired. And why? That the candidates for the license might be enabled to spend more money in qualifying themselves for the important duties of their station—an example of magnanimity and disinterestedness unheard of in the history of incorporated bodies.

In my own recollection the curriculum has been judiciously extended, as was rendered necessary by the state of the times, and by the improvement of science, so that, in the course of the last thirty years, the expense imposed on candidates for the diploma has been, I suppose, quadrupled; whilst not one shilling has been added to the fees demanded by the College for more than double that time, nor any regulation made which promoted the peculiar interests of the Fellows, collectively or individually. The moderate fee of £7 5s. is the amount levied on each member on receiving his diploma, which is the essential license of the general practitioner of Scotland, and it qualifies for the army and navy. The course of study and training prescribed is very perfect, and is admirably adapted to fit those who enjoy its advantages, to practise the healing art, in the most extensive sense of the term, successfully. The general practitioners of Scotland, as a body—the *Members* of the College of Surgeons—are, beyond all doubt, in point of scientific acquirements and respectability, superior to any other in Europe: and, at home and abroad, they are respected accordingly. With the exception of a few situations in the metropolis—and these of little importance in a pecuniary point of view—they are eligible to all public situations of repute. Of the merits of estimable men who have been instrumental in placing the Edinburgh College of Surgeons in the exalted position it occupies, as a Board of Medical Education, it is impossible to speak in too high terms. On this subject I could say much, but that were irrelevant at present. I would, however, through the medium of your extensively circulated publication, pay a just tribute of praise to the names of the venerable Dr. Thomson, Emeritus Professor of Pathology in the University of Edinburgh, the late Dr. Kellie of Leith, Mr. William Wood, Dr. Maclagan, Sir George Ballingall, Dr. John Campbell, and Dr. Huie, whose unostentatious exertions in this good work, fairly entitle them to rank high in the history of their country, as benefactors of mankind.

In regard to Fellowship with the Edinburgh College of Surgeons, it is not considered of consequence, except to those residing in the capital—and even in Edinburgh and Leith, there are many practitioners enjoying, deservedly, high respectability and ample emoluments, not *Fellows*—and who have no desire to be so.* The fees payable on entrance as a Fellow, are high, and there is a second examination. The condition of the medical profession in Scotland affords conclusive evidence of the accuracy of the opinion delivered in my last communication, relative to the absurd importance attached to the Fellowship by the general Practitioners of England. The state of public feeling in the Northern division of the kingdom also tends to shew that the fears of many persons in the South are groundless, as to what they call *grades* in the profession. If the members of that class—the Licentiates in Medicine and Surgery—which they choose to consider a degraded class, be sufficiently educated and properly trained for the performance of their important professional duties, as certainly will be the case, under the superintendence of the Council of Health, the natural result will be, that they will find their proper place—a respectable, honourable, and lucrative one—in the medical commonwealth. It will be obvious that whilst, to obtain peace and harmony, I would advise that the wishes of the *present* members of the College of Surgeons, as to Fellowship, should be complied with, under certain restrictions, I am convinced they attach a degree of importance to carrying the point, to which it is not entitled. The degree of Licentiate in Medicine and Surgery, and the other degrees in the profession, as proposed by Sir James Graham, I conceive to be a wise arrangement, and one which will be conducive to the best interests of the profession and the community.

LUCIUS.

Devonshire, March 31, 1845.

* The entire number of Fellows in 1844 amounted to 99, of whom 82 resided in Edinburgh and Leith; 2 in Glasgow; and only 3 in the provinces throughout Scotland.—The remaining 12 reside in England, or abroad.

THE PLOT MEETINGS OF WAKLEY AND HIS CLIQUE.

(To the Editor of the Medical Times.)

SIR.—As the Editor of the *Lancet* appears to have overlooked the duty of an impartial journalist, by not inserting the enclosed reply to his correspondent, a "Lover of Truth," I shall feel obliged if you will allow it a place in your columns, together with my reply to Mr. Hillier.

I am Sir,
Your obedient servant,
E. T. MEREDITH.

15, Charles Street, April 21st, 1845.

(To the Editor of the Lancet.)

SIR.—If your correspondent a "Lover of Truth" in this day's *Lancet*, will throw off his disguise and favor the public with his real name, without indulging in vulgarisms and personalities, I may possibly be induced to give him my reasons for believing that the meeting at the Princess' Theatre, "professedly called in the name of the National Association of General Practitioners," was in reality got up by the discordant remnant of the Protection Assembly. Circumstantial evidence is often sufficiently conclusive, and is frequently far less open to suspicion than more direct assertion; and a real lover of truth need not be told, that instances are not wanting in which the accused, however clearly convicted, has pertinaciously denied the justice of his sentence. I admit that the members of the assembly *did* number 1,200, probably more; but where are they now? One half, perhaps, is the outside that still acknowledge the society, notwithstanding the original names may be retained on the roll; and I would ask, not invidiously, how many even of these now take any interest in, or connect themselves in any way with its proceedings. It is melancholy to contemplate the causes that have contributed to diminish its numbers and moral weight, and so reduce the assembly from its once high estate and apparently dignified position, to the least influential of all the medical associations. If, as your correspondent observes, the "assembly" has made such generous "sacrifices of time and money" in the cause of medical reform, there surely must be something radically faulty in its constitution and policy, when the greater portion of men of standing in the profession withhold their assent to its operations. Doubtless, these remarks, in some quarters, will be rather unpopular, but I have not to learn that truth is often unpalatable, and, therefore, am not unprepared for the obloquy that is frequently endeavoured to be cast, not very sparingly, upon its martyrs.

I have no other interest in medical reform than what is common to the whole profession, viz.—the attainment of good medical government; neither am I the apologist or censor of any Association, but, Sir, as an independent observer of passing events, I cannot be blind to what I have seen, nor deaf to what I have heard at several medical meetings held within the last few months, and however difficult it may be to select individuals, who are not only free from, but can steer clear of, all suspicion of interested motives, enough has transpired at those meetings to convince me to whom at least, the profession ought *not* to trust the adjustment of the important and complicated question of medical reform.

I *depend* upon your impartiality as a public journalist to insert this communication in your next number, and am,

Sir,
Your obedient servant,
E. T. MEREDITH.

April 22nd, 1845.

[Of course Mr. Meredith depended in vain, as all must who depend on a non-entity. Mr. Meredith made the great mistake of coming in personal contact with men without character and without honour, who would unswear the most known truths to set an opponent wrong, and sink, any hour, into any depth of lying, or calumny, to serve a momentary purpose. The Protective Assembly—that beggarly receptacle of the scum of the profession—that worthy society of the Wakleys, the Ruggs, and the Lynchs—is actually defunct. It has not thirty members who would give sixpence to prolong its discreditable existence a day.—ED.]

Mr. Meredith also sends us a note addressed to Mr. Hillier, in which he vindicates a former letter published in the "Transactions of the National Association of General Practitioners." Mr. M. unceremoniously gives the *coup-de-grace* to the statements of the persons who held the hole and corner meetings under the name of the National Association, but the assertions of the plot are really so intrinsically groundless and worthless, not to say palpably nonsensical and false, that they are beneath alike notice and discussion. Imagine *Medical Protectionists*—the Ruggs, Lynchs, and Wakleys—whose committee was appointed by a meeting of thirty persons (the principal speculators positively hawking about their vacancies through the small room without being able to fill them)—imagine, we say, these men virtuously irate at the *unconstitutional* appointment of a committee by a public meeting comprising at least from three to four hundred gentlemen; a committee appointed, too, in the teeth of a miserable, factious opposition that could only number fourteen or fifteen votes! Have these gentlemen any sense of shame? Have they even a remote guess at what, in common decency, should be paid to the feelings of respectable people? If heedless of infamy, need they be so reckless in shewing it? In truth, we cannot comprehend them.

Gentlemen admitted Members of the Royal College of Surgeons on Monday, April 14th., 1845:—T. Atchison, J. Palmer, J. Richardson, J. T. Griffith, T. Blake, J. T. C. Ross, A. Priest, T. G. Stockwell, J. Vass, and W. G. Dalgarns.

Prize Clinical Reports of Surgical Cases treated at the Queen's Hospital, Birmingham, in the Practice of W. Sands Cox, F.R.S., Senior Surgeon. By JOHN MOORE, Student of Queen's College, and Resident Medical Officer of the Queen's Hospital, Birmingham.

These reports speak favourably of Mr. Moore's industry and Mr. Cox's practice. The cases in general are the ordinary fractures, dislocations, &c., that visit every large hospital; but those marked 3 and 4, are instances of a rare form of dislocation of the thumb, that in which the base of the first phalanx is thrown back upon the trapezium, a form of dislocation unknown to modern writers on surgery, even to Sir Astley Cooper. Twenty-six cases complete the book.

Outlines of Chemistry, for the Use of Students. By WILLIAM GREGORY, M.D., Professor of Chemistry in the University of Edinburgh; *with various Engravings on Wood. Part I.—Inorganic Chemistry.* London: Taylor and Walton.

This is a deservedly successful work, and we have little doubt that it will become that very profitable thing both to author and publisher—the Universal Class Book on its subject. The work is very neatly got up, is well illustrated by engravings, and is all that a class book on Inorganic Chemistry should be.

ENCYSTED TUMOUR IN THE OMENTUM.—Mr. Russell, at a meeting of the Sheffield Medical Society, narrated the case of a female, aged 46, of light, florid complexion and sanguineous temperament, and who, having used violent exertion while attempting to rescue a child from danger, in stooping suddenly, after running, felt something give way at the pit of the stomach. She became very faint, and pain ensued, which has since continued, more or less. Three months after she observed her body to increase, and suffered from a sense of fulness, with great tenderness on pressure, at the pit of the stomach. When first seen by him her countenance expressed extreme anxiety. She was lying on her back, with the shoulders raised, and the legs drawn up. Breathing laboured; no power of turning to either side; the abdomen fully distended, and there was great soreness on pressure, especially between the umbilicus and the ensiform cartilage. The integuments of the lumbar region and the lower extremities were anasarcous; pulse 130 to 140, sharp; urine, four ounces in twenty-four hours, turbid, milky, with phosphoric odour; the albuminous tests produced no effect; bowels had been much constipated; mammæ completely absorbed; no trace of pregnancy *per vaginam*. The symptoms, in spite of the treatment, becoming urgent, the operation of tapping was resorted to, when two gallons of fluid, containing flakes of lymph and pus, were evacuated with great relief. A large tumour was then distinctly traceable, occupying the whole space from the umbilicus to the ensiform cartilage, filling the left hypochondriac region, down to the crest of the ilium. It was firm, but pressure gave great pain and the lower margin was irregular. The fluid again accumulated in a short time, and the tapping was repeated. The tumour had much increased; legs much more swollen. The constitutional disturbance increased; the breathing became more laborious; cough troublesome; pulse much weaker; skin hot; legs more swollen, and very cold. Incisions were made in the limbs to relieve their tension, but mortification ensued, and she soon sunk. *Post-mortem*, about twenty-four hours after death. On laying open the abdomen, the peritoneum was found to be much thickened, throughout, and very extensively adherent. An immense tumour occupied the place of the greater omentum, extending into the right and left hypochondriac regions, from the ensiform cartilage downwards, as far as the umbilicus, and backwards, so as to press upon the large abdominal vessels. Its upper surface was smooth and free from ulcerations but contained several encysted tumours, about the size of pigeon's eggs. In the folds of the omentum, were three or four cysts, containing serous fluid. The minor omentum was much distended with fluid, filling up the greater portion of the right hypochondrium. That part of the tumour which extended into the left hypochondrium consisted of a number of large blood-vessels, resembling in appearance an expelled placenta. The inferior surface was covered with coagulated lymph, from which pus had been very plentifully secreted. The tumour was contained entirely in the folds of the omentum, and had no other attachment. It weighed upwards of ten pounds. With the exception of the transverse arch of the colon, which was much contracted, the alimentary canal was normal. The liver, spleen, pancreas, and kidneys, were small and flabby, otherwise not unhealthy. The uterus was vascular, but not impregnated. There was an indurated tumour, about the size of a chesnut, in the left ovary. The chest contained between two and three pints of fluid. Lungs and heart not examined.

CAUSES OF MORTALITY IN PUERPERAL FEVER.—Dr. Blackmore says, the causes of the mortality of this dire disease may be referred to these heads:—(a) The specific nature of the disease, *e. g.* its extensiveness, its intrinsically asthenic and putrescent character; the sedative influence on the vital powers of the accumulation of the poison in the system, or of the congested venous blood in the abdominal viscera. (b) Early neglect of remedies; many cases being incurable, unless properly treated within twelve hours of the attack. (c) Improper treatment, *e. g.*, large bleedings, abuse of turpentine and opium. This treatment, indeed, may have been pursued without fault in the practitioner, who can sometimes only learn from painful experience, the real nature and proper remedies of the malady. An examination of one's own cases and others on record, will however, show that failure has been owing to the treatment *not being modified according to the changeful states of the case*, and the true character of the epidemic. Profuse bleedings, so generally practised in the early cases, and sometimes a more moderate bleeding at a late period of the disease, has evidently in later epidemics, served only to augment the serous effusion, and hasten a fatal collapse. He does not however, admit the paralysing belief, which has been derived from misfortune, that in a large proportion of cases all treatment is useless from the time when the medical man is first called in, and is convinced that some patients might have been saved, *Deo favente*, if the practitioner could have seen the case *unintermittingly*, or had had a judicious assistant on the watch during his absence. (d) The *antecedent state of the patient* has sometimes made the attack fatal—*e. g.*, a full-blooded irritable state of the constitution, or debility with poverty of the blood, or an indefinable unhealthiness connected with a sickly season, or a crowding in lying-in hospitals, or a stomach complaint, or disease of the ovaries.

SCIRRHOUS TUMOUR OF THE CERVIX UTERI.—At a meeting of the Birmingham Pathological Society, Mr. Elkington presented an uterus, in which there was a tumour near the cervix, apparently of a malignant character. The uterus and its appendages were very vascular; the lips of the os uteri red and granular; the cervix thickened and hard, particularly at its inner margin; to the right of the cervix there was a tumour about the size of a small hen's egg, of a firm structure, having in the centre a hard scirrhous feel; *posteriorly* the right ovary was connected with this tumour. In removing the uterus, the tumour, which was firmly adhering to the right obturator foramen or near to the right groin, was cut through, and a portion, perhaps nearly half, left behind. The right ovary and right Fallopian tube were doubled backwards, and adhering to the back part of the tumour and side of the uterus, as low down as the cervix, and within a few lines of the os; the left ovary was rather small, and on its upper surface posteriorly there was a large cicatrix of a hard gristly structure, and paler than the surrounding part, to which the Fallopian tube was adhering by small fibrous bands. The inner surface of the uterus was very vascular, and lined with a bloody fluid; the os was a little open.

NEW TROCAR FOR THE OPERATION OF PARACENTESIS THORACIS.—Dr. Fletcher exhibited a trocar and canula, which he had constructed to prevent influx of air into the chest during the operation of paracentesis thoracis. It consisted of the following modification of the common trocar and canula:—The canula is lengthened beyond the shoulder three quarters of an inch, and of course the trocar is so much longer than in the common instrument. To this lengthened-out portion of the canula is to be attached a piece of intestine of some small animal, which is pulled out as the trocar is withdrawn, and hangs down about three quarters of an inch. The trocar is passed along the canal of the intestine into the canula, and the loose portion is doubled up upon the shoulder of the trocar when the instrument is prepared for the operation. Dr. Fletcher said, that he thought this modification of the instrument would be useful in all cases: by including the lengthened-out portion of the canula in the grasp of the operator, the handle was somewhat lengthened, and the trocar and canula being held together, a greater degree of firmness would be attained. The lengthened-out portion allows much greater facility for catching the fluid as it runs from the canula than in the common form of the instrument; and the intestine permits the operator to check with very great ease the rapidity of the discharge of the fluid, which is sometimes very necessary in the operation of paracentesis abdominis.

PUERPERAL FEVER.—Dr. Blackmore, in a paper published in the *Provincial Medical Journal*, says—The phenomena of the cases suggest the following deductions:—(1.) That puerperal fever is a specific affection, which, when occurring either epidemically or sporadically, presents itself under *two forms*, which constitute merely *varieties* of the disease, and not specifically different maladies. They may be designated the *synochal*, sthenic, or more benign; and the *typhoid*, asthenic, putrid, or more malignant. The general form of puerperal fever at any period, usually resembles that of other febrile diseases, particularly synochus, and various exanthemata, and also of some purely local inflammations, which prevail at the time in the same place; and the analogies then observable among all these affections, strongly illustrate the character of each. The disease in both varieties is of a *malignant* nature, in comparison with common fevers and inflammation; it assumes a more asthenic character in hospitals, low marshy situations, and in a variable autumnal season. (2.) Disorder in the system, signified by an indescribable uneasiness, or a change in the nervous feelings, a quickened pulse, and disordered breathing, generally precedes the *manifestation* of the local affection, although to an inattentive observer these two elements may seem to begin and go on with an equal step. (3.) An extensive and severe abdominal affection is an essential part, and a great source of the danger, of puerperal fever. This local affection has *various seats*; in some cases, the *peritoneum* of the intestines is chiefly affected; in others, that of the stomach, or of the uterus and its appendages. In all the cases which have come under Dr. Blackmore's observation, the parietal or the visceral serous membrane has been more or less the seat of disease. Disease in the mucous membrane of the uterus, intestines, and stomach, forms occasional complications with the peritoneal affection, and severely aggravates the danger of the case; and sometimes this membrane is the original seat of the abdominal affection. In a majority of the cases, the rapid extension of the inflammation, wherever be its seat, is a distinguishing character of the local disease. In some cases, particularly of the typhoid form, besides the former organic lesions, there is a softened state of the liver and spleen, gangrene or fœtid suppuration in the uterus and ovaries, and a softened or gangrenous state of the lungs.—(4.) The specific character of the disease is not derived from an affection of any one organ or texture, nor from any particular morbid state of the abdominal viscera. The character of the constitutional affection in any particular case, the sympathetic or secondary fever, will, indeed, vary with the nature of the local disease as to its erythematous, suppurative or gangrenous condition; but in genuine puerperal fever, the primary fever and the local element are equally the pure results of its specific exciting cause. The malignity of the

disease, moreover, is not the effect of uterine phlebitis, and absorption of pus from the veins; nor even of gangrene of the viscera. The cases have shown an equally rapid course, in which vascularity and effusion into the peritoneum were the only morbid appearances. The degree of the local affection is variable; in some few cases forming the minor element of the disease; practically, however, it is alwas an important part thereof and a great source of danger; in its symptoms, and in its progress, it is remarkably different from those of abdominal inflammation from other exciting causes. (5.) The malignity of the disease is not more mysterious than that which marks erysipelas, the other exanthomata, and petechial typhus; and it appears to be analogous to these diseases when extensively prevalent and fatal. This malignity is characterised by the severity of the early rigor and shiverings, by the early acceleration of the pulse, and of the breathing, by the intensity of the pain, or by a want of correspondence in the degree of the pain with the other alarming symptoms, and by the rapid sinking of the vital powers. The symptoms of a severe affection of the nervous system, so often seen in bad cases of synochus or typhus, were absent in the fatal cases of puerperal disease that came under Dr. Blackmore's notice. The malignity is also manifested by the rapid extension of erythomatous inflammation over the serous and mucous membranes of the abdominal and pelvic viscera, and its attendant serous effusion; and by a suppurative or gangrenous affection of the lungs, the liver, the spleen, and of the subcutaneous and inter-muscular cellular tissue of the trunk and limbs.

A SELECT PRACTICAL FORMULARY.

TRANSLATED FROM THE FRENCH OF M. FOY, PRINCIPAL PHARMACIEN OF THE HOSPITAL ST. LOUIS, AT PARIS.

SOAP OF JALAP. one ounce of powdered jalap resin; two ounces of scraped medicinal soap; dissolved in a sufficient quantity of alcohol at 82°, with the aid of gentle heat, then evaporated to the pilular consistence and preserved. Mode of exhibition—ten to twenty grains for children, as a purgative. *** The jalap soap of the formulary of military hospitals, is prepared with one ounce of grated medicinal soap, and two ounces of tincture of jalap The soap is dissolved in the tincture, then evaporated to the consistence of pills, and set aside for use. Mode of exhibition—four to six pills, weighing four grains each, in the course of the day.

SOAP, MEDICINAL: soap prepared with twenty-one parts of oil of sweet almonds, and ten parts of liquid caustic soda at 36°. *** A stimulant medicine employed as discutient in chronic enlargements, especially in those of the abdomen, as a diuretic, combined with camphor, nitrate of potash, &c., in the treatment of calculous nephritis, and other affections of the kidneys. Mode of exhibition—in bolus or pills, weighing from six to ten grains, and more daily. Its use should generally be continued for three or four weeks. It may also be employed in the form of bath, in the dose of from two to four ounces and more, in chronic affections of the viscera, or of the skin.

SOAP, SULPHUROUS (J. Franck): four ounces of white or green soap, four ounces of sublimed sulphur, half a drachm of essence of bergamotte, mixed together with the aid of heat, and of a little water to dissolve the soap. Mode of exhibition—half an ounce to an ounce in frictions in cases of itch. The soap, described as Spanish—a very alcaline soap—has been recommended by Dr. Graeffe against the itch.

SOAP, VEGETABLE OR GUMMY ALCALINE POWDER: one drachm of crystallised subcarbonate of potash, one ounce of powdered gum arabic, triturated together for a long while. Mode of exhibition—thirty to sixty grains in a little water, in enlargement of the abdominal viscera.

SCABIOSA (Flowers)—Infusion. one to three drachms to a quart of water. Diaphoretic, but rarely employed.

SCAMMONY—Powder: two to six grains in bolus or pills, and progressively to twelve and sixteen grains; tincture, ten to thirty drops in an appropriate menstruum. A drastic very little employed at present, probably on account of the difficulty of procuring it pure. Scammony has been advantageously exhibited in certain cases of habitual constipation, passive dropsy, &c.

SQUILLS: two to ten grains in bolus or pills, or by the endermic method; wine, half an ounce to two ounces; oxymel, half an ounce to an ounce, in an appropriate menstruum; vinegar, one to two drachms. In large doses, squills act after the manner of the narcotico-acrid poisons, in small doses, its action is principally on the kidneys, the secretion of which it increases. Squills also exercise a well-marked stimulant influence on the secretion of the mucous membranes, and especially on that of the bronchial tubes. Great benefit is very often derived from the use of preparations of squills, in the treatment of pulmonary phthisis, mucous catarrh, the asthma of old people, &c.

SEDLITZ POWDERS: eight drachms of tartaric acid, divided into twelve packets, and put up in white paper: also, eight drachms of bicarbonate of soda, twenty four drachms of tartrate of potash and soda, mixed together, and divided into twelve packets, put up in blue papers. Mode of exhibition—a packet of the acid is dissolved in a glass of water, to which a packet of the salt is added, and then stirred together. *** A gazeous, cool, and laxative drink.

SECALE CORNUTUM—Powder (which ought to be always prepared fresh, or else wrapped up in tin-foil): ten, thirty, 72, and 144 grains, in a little sugared water, or in lavement or injection, when the strength of the patient cannot bear it. Decoction, or better still, infusion, half a drachm to two drachms to five and ten ounces of water. Pulverulent conserve: half a drachm to three drachms, mixed with a little water. The obstetric virtues of the secale cornutum have been known for a long while. The midwives of the Lyonnais have used it to quicken labour from the time of Camerarius. This substance is now universally employed. Its special action consists in assisting the contractions of the uterus, when that organ endeavours to free itself of the products of conception. It is successfully administered when the labour is retarded by inertia of the womb, and when the patient is weakened, either by repeated pregnancies, or from some other cause. It is also given with advantage to change the pains in the loins, which occur during labor, into expulsive uterine pains. Before the secale is exhibited, it should be ascertained by the touch whether the position of the child is such, that its expulsion is retarded solely by the feebleness or absence of the uterine contractions. In no case should it be employed, until labour having already commenced for a certain time, it has been ascertained that the child presents either by the head or the nates, that its size is not disproportionate to the dimensions of the pelvis, and that the vulva is not too narrow. The secale cornutum also causes the expulsion of the placenta, and of the coagula which are formed, and which remain in the uterus after the completion of labour. It is also of service in cases of abortion, fluor albus, uterine hæmorrhage after labour, white discharges, &c. Its exhibition should be preceded by sufficiently free abstractions of blood in cases of general plethora. Puerperal convulsions are not a contra-indication to the use of secale cornutum. Some cases of palsy have been improved, and some fragments of calculi arrested in the canal of the urethra after lithotrity have been expelled by the use of the secale cornutum.

SALT OF ALEMBROTH: equal parts of porphyrised corrosive sublimate, and sal ammoniac.

SALT, BITTER, OF RIGATELLI: an unknown salt, recommended by Rigatelli, as a succedaneum of the sulphate of quinine.

SALTS OF CHELTENHAM. (English formula), a mixture of equal parts of Glauber's salts, Epsom salts, and table salt Mode of exhibition—one to six drachms as a purgative.

SALTS OF CODEINE (hydrochlorate and nitrate) · salts of very little activity, and rarely used.

SEL DUOBUS· see sulphate of potash.

SALT, FEBRIFUGE OF SYLVIUS; see chloruret of potassium.

SALT OF GREGORY: see double muriate of morphia and codeine.

SALT OF GUINDRE (Cadet). an ounce and an half of efflorescent sulphate of soda, twenty four grains of nitrate of potash, one grain of tartar-emetic. Mode of exhibition—five to six drachms in the morning fasting, in an appropriate menstruum.

SALT OF LA GARAIS: see dry extract of bark.

SALT, ENGLISH VOLATILE; two parts of powdered sal-ammoniac, three parts of dry carbonate of potash, mixed together quickly, and put into bottles stoppered with emery. *** A mixture preferred to ammonia, the gas of which evaporates too abundantly at once.

SALT, VOLATILE OF AMBER: see impure succinic acid.

SEMEN CONTRA—Powder or in infusion. one to three drachms to a cup of water or milk: syrup, half an ounce to an ounce, in an appropriate menstruum. An anthelmintic very much employed against ascarides and lumbricoides.

SEEDS, HOT: mixture of equal parts of aniseed, fennel, coriander, and carraway seeds.

SEEDS, COLD: mixture of equal parts of gourd-seeds, pasteque, melon, and cucumber seeds.

SEEDS OF MUSTARD: see mustard.

SENNA (Leaves and Follicles)—Powder (rarely used): twenty to sixty grains in bolus or pill. cold infusion, one to three drachms to a pint of water; syrup, half an ounce to an ounce, in an appropriate menstruum; extract (rarely used), twenty to thirty grains in bolus or pills, tincture (rarely used [?]), half a drachm to two drachms in a julep, potion, &c. Senna possesses well-marked purgative properties, nevertheless, it is rather less employed than it used to be. Administered in large doses, it violently irritates the gastro intestinal surface, and gives rise to nausea, and colic. These inconveniences are obviated by giving it in moderate doses, and by combining it as in England, with aromatic substances, such as cinnamon, aniseed, ginger, fennel, &

(To be continued.)

GOSSIP AND NEWS OF THE WEEK.

THE SELF-DEGRADED.—The following members of the Royal College of Surgeons of England were admitted to the Fellowship on the 17th of April, 1845:—Messrs. Edwin Canton, St. Martin's Lane; Wm. White Cooper, Tenterden Street; Wm. Edwd. Crowfoot, Beccles; Henry Davis, Tenbury; John Eric Erichsen, Welbeck Street; George Harcourt, Chertsey; Wm. Augustus Hillman, Argyll Street; Edw. Jackson, Chaddesley, Corbett; Alfred Keyser, Norfolk Crescent, Hyde Park; Wm. Salmon Lucas, Featherstone Buildings; Robt. Grueber Shute, Mecklenburgh Square; James Stilwell, Uxbridge; Christr. Maxwell Cowell, St. Helens; Jas. Thos. Ware, Russell Square; John Ludford White, Dowlais.

Gentlemen admitted Members of the Royal College of Surgeons on Friday, April 11th., 1845:—J. Gardner, R. R. Jefferiss, C. Muscroft, Wm. Mc'Hugh, J. C. Wordsworth, W. H. Thornton, T. B. Horne, T. A. H. Dodd, R. R. Noble, and R. S. Cross.

Gentlemen admitted Members of the Royal College of Surgeons on Friday, April 18th., 1845:—E. Snell, J. Duncan, W. M. Richards, T. Fisher, T. Alderton, P. Roscow, E. C. Odling, W. Lightfoot, R. Abud, J. Ody, W. Smith, J. Hewitt, T. D. Scott.

Gentlemen admitted Members of the Royal College of Surgeons on Friday, April 21st., 1845: R. S. Finch, C. Vicary, B. Micklethwaite, H. Wiglesworth, R. M. Bowman, F. H. Johnson, G. A. Hallion, J. C. Austen, T. Frampton, and E. Cripps.

CHINESE BOTANY.—The *Gardener's Chronicle* tells of the arrival at Hong Kong, of Mr. Fortune the Botanist. His collections for Europe are said to occupy many chests which are by this time on their way to England. Mr. Fortune had met with many beautiful shrubs, and it is hoped that a large part of them will prove hardy, or nearly so. Vibernums, with heads of large flowers, like a hydrangea; moutans in great variety; peaches, apricots, roses, handsome creepers, azaleas, daphnes, both sorts of the curious hexangular camelia—a great desideratum, for it must be beautiful of the varieties; others from Fokein: hydrangeas, a very fine double white gardenia, with flowers as large as a camellia; a curious chrysanthemum, named as a perfect gem; new pines, honeysuckles, and plums, are among the rarities mentiond as being actually on their way to England.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—Gentlemen who have obtained Licences during the present year.—Licentiates.—Griffith, W. J., St. John's Square, Handfield, C., 3, New Street, Brompton Road; Stanton, J., Upper Charles Street, Northampton Square.—Extra-Licentiates.—Allen, John S., Belfast; Allen, J., R.N., Caroline Street, Bedford Square; Burgess, W. Liverpool; Browne, J. C., Weston-super-Mare; Carey, Sampson, Paris; Carter, H. Freeland, Plymouth; Carter, Matthew, Reading, Berks; Deshon, H. C., Devonshire; Hitchcock, Thomas, Winchester; Loman, Frederick, Bristol; Moore, Thomas R., Salisbury; Robertson, H. Amelius Powell, Bristol; Roper, George, Bristol; Rudderforth, Edw. Henry, Twickenham; Sloan, John R., Navy; Smith, John, Plymouth; Smythe, George, 17, Northumberland Street; Stanton, John, Clifton; Stewart, Robert; Tatum, G. R., Salisbury; Turley, Edw. Asbury, Worcester; Witt, George, Bedford.

In the House of Commons nothing has been done this week, except the announcement of Sir James Graham, that he will mention to-night (Friday) the alterations he proposes to make in his Bill. The second reading is fixed for the same evening. The Minister states the principle of his Bill to be uniformity of education, and free liberty for practice to medical men in every part of Great Britain and Ireland. Both are good aims, if the *uniformity* of education be a *high*, and not a low (two years') uniformity, and we own we should have thought that the true principles of a measure of medical reform would be, first, uniformly high educational qualification; secondly, government by representation, *id est* merit; thirdly, restriction of quack practice, alias playing at assassination, or mutilation; fourthly, uniform rights to practice.—Mr. Wakley has also given notice for a Committee of Inquiry into the Charter—a cause of procrastination that, as the *Morning Chronicle* remarks, will only obfuscate what is already sufficiently clear.—Mr. Guthrie has also presented a petition, praying that nothing may be done in the way of medical reform, till the College be put on a better footing with its members.

Some of the Medical Protectionists are trying to make arrangements to get up a dinner to Mr. Wakley. We are really curious to know who will be the *respectable* stewards *besides* Messrs. Rugg and Lynch. It will be our duty to take note of their interesting proceedings.

No. 293 **SUMMARY.** MAY 3.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

Yesterday we were on the subject of paralysis, and considered the two kinds, hemiplegia and paraplegia; I also mentioned some of the varieties, and I have now to describe some more partial kinds of paralysis.

Ptosis, a dropping of the eyelid, is a partial paralytic affection. There is an inability to direct the eye, and strabismus, a loss of power of the director from paralysis of the third nerves. This is more commonly a separate disease. The situation of the third nerve in the more anterior part of the brain towards the nervous centre renders it exposed to pressure from the same circumstances, that cause pressure on the nervous centre.

Another kind of paralysis is that where the eye remains permanently open from paralysis of the orbicularis. It is connected with paralysis of the portio dura, the nerve influencing the muscles of the face. The seventh nerve is paralysed, and there is a want of power of closing the eyelid, the result of which is inflammation of the eye from the absence of lacrymation. The paralysis of the muscles of the face may arise from paralysis of the portio dura, a branch of the seventh nerve, or of the motor branch of the fifth nerve. When these branches are injured, it is chiefly the muscles of mastication that are affected, and then sensibility is impaired at the same time; on the other hand, if there is any paralysis of the muscles of the face—the portio dura branch—and if this arises from disease within the head, in all probability there will be deafness. Tumour within the head, producing pressure on the two branches of the seventh nerve, may produce paralysis of the portio dura, and press also on the acoustic nerve. When paralysis of the muscles of the face occurs, it may be considered to arise from paralysis of the portio dura. This is very peculiar, in so much as it is commonly connected with paralysis of the fifth nerve, but the paralysis of the portio dura of the seventh nerve, alters the expression of the face to a much greater extent. It affects those muscles which are especially concerned in expression, and, consequently, all the time the healthy side of the face is influenced by affections of the mind, joy, grief, and so on, the other side of the face is blank, or exhibits a dolorous expression, tears often running from the eye. This is a very curious phenomenon, and the ludicrous effect is very striking. When the patient attempts to laugh he exaggerates the contrast still more. Paralysis of the portio dura arises from temporary causes; tumour of the parotid gland, or merely from cold affecting one side of the face, in which case it comes on quite suddenly. Partial paralysis arises from paraplegia, from inflammation or effusion in the sheath of the spinal nerves after hepatic affections, from exposure to cold, and other causes which produce rheumatism.

In all these different cases the treatment to be used is, in the first instance, antiphlogistic, and to be followed by colchicum, iodide of potassium, and so forth; cupping, leeching, and fomentations, and warmth to the parts, and afterwards using blisters, and other modes of counter-irritation. This will generally relieve to a considerable extent, and, if the disease is recent, altogether remove the paralysis. Sometimes the paralysis remains, and, under these circumstances, the stimulus of electricity is of great use in partially restoring the power of the muscles. Strychnia, locally applied, is also in these cases useful. The best form is the acetate, or some mild salt, applied in solution.

There is a class of affections which are not serious in their results, but nevertheless should be noticed:—Partial paralysis of the eighth and ninth nerves causing difficulty of articulation and deglutition, and sometimes an impediment in the breathing, or an affection of the respiratory branches. This is often connected with disease of the cerebral centres, something affecting the circulation of the whole brain, and hence difficulty in articulation and a tendency to spasmodic asthma, or spasm of the glottis; or a closure of the glottis is produced temporarily from determination of blood to the head, and the eighth and ninth nerves are exposed to pressure from the arteries forming the circle of Willis. Sometimes it produces giddiness, and this is of course more important than the other case, because it may lead if neglected to a more serious affection of the brain.

Now there is sometimes paralysis of sensation, or actual loss of sensation in the whole body, and there are many instances of loss of sensation of spinal senses. There is paralysis of the optic nerve, or amaurosis, in which there is paralysis of the retina, though no visible lesion can be detected in the eye itself. With this condition the pupil is sometimes contracted, sometimes dilated, and sometimes natural. It is a very common kind of paralysis, and may occur in connexion with cerebral disease, but more commonly it occurs as a symptom of partial disease, and the reason why the optic nerve is especially liable to derangement, is the same as that mentioned with regard to the eighth and ninth nerves. Throughout its whole course it is in intimate communication with the vascular plexus in the distribution of the arteries from the *crura cerebri* to the *thalami nervorum opticorum*, and then you trace it until it enters its proper foramen, where it is distributed to the retina accompanied by a fine extensive vascular plexus. Now you can understand how it is that the optic nerve throughout its whole course is liable to disorder. A person may be lying or stooping, and on a sudden there is great palpitation, and immediately a state of darkness is produced at each beating of the heart. This diseased vision occurs not only in diseases of the brain, and the nerve, but in the various extreme states of the circulation, plethora, and anemia, and frequently from hæmorrhage. So likewise in functional disorders of the stomach or liver, the sight is apt to become affected. This paralysis is therefore a common sign of these conditions. It however sometimes arises from excitement of the optic nerve itself, and from excessive use of the eyes; temporary, or permanent glares of light and flashes of lightning have produced it. In persons who have had amaurosis and have died, no distinct lesion of the nerve itself has been discovered, generally speaking, and though such has been found, the disease is not to be indexed by post mortem examinations. It only shews that we are not quite up in the structure of the nerve. Paralysis of the optic nerve may be partial, affecting only parts of the retina; here it is, that we sometimes see spots or specks on the cornea. It is more a disease of the eye itself, and the general health is not much affected. There is another affection that borders on this, namely *nyctalopia*, a loss of the power of modification of the sensibility of the optic nerve, so that persons so affected can only distinguish objects in broad day-light; or, on the other hand, in what is called *hemeralopia*, where they only see in the same light in which owls and bats see. Most persons affected with nyclatopia cannot see by night, the paralysis of the nerve being such that an indistinct light is insufficient to produce an impression on the nerve. *Hemeralopia* means excessive sensibility of the retina, and *nyctalopia* diminished sensibility. Deafness is another variety of paralysis, sometimes connected with disease of the nervous centres, and is a very common sign in the course of various cerebral affections, fevers and so forth. Not only are the nervous centres affected but the distribution of the nerves, and there are many cases of paralysis constituting deafness, arising from disorder in the internal ear. If it arises from paralysis of the seventh nerve, it ought to affect the portio dura also. Deafness with or without noises in the head is produced commonly in connexion with determination of blood, the manner in which disturbance of vision is produced; and after congestion and great loss of blood. Various circumstances that influence the circulation, will affect the hearing, taste and smell, but these more commonly result from some changes in the membranous expansion on which the nerves are distributed.

The next subject is *hydrocephalus*, water in the head, or dropsy of the brain. Acute hydrocephalus is to be considered an inflammatory affection; in fact, it has been improperly termed hydrocephalus, because though watery effusion is sometimes found, it is not of constant occurrence. Chronic hydrocephalus is obviously dependent on an excessive effusion of water or serum in the interior of the ventricles, causing an unfolding of the convolutions, and expanding the brain into a sort of sac, or else there is sometimes effusion on the surface of the brain under the arachnoid, compressing the convolutions to a small portion at the bottom of the skull, the accumulation taking place very gradually, and causing an expansion of the head, and opening of the fontanelles, and sinuses; in fact, an enlargement in every way. Hydrocephalus may be congenital; a child may be born with a watery brain, or it may come on after birth, but,

generally speaking, it occurs early in life, before the fontanelles are closed. In some cases there is no enlargement, and sometimes even the skull is closed at birth, and on opening the head it is found that instead of brain there is a quantity of water. When hydrocephalus comes on after birth, as a disease, its approach may be accompanied by a remarkable excitability, or sensibility, a readiness to laugh or to cry at small things; there are various circumstances shewing an increased excitability of mind; the moral feelings, and the memory are impaired, and often in the course of the disease, convulsive fits occur, particularly during the night, accompanied by a piercing cry. Then the child is usually very heavy, it sleeps much, and complains of a dull pain in the head, which is heavy, and leans on the shoulders when carried; the child will not walk, and in case of sudden motion, stupor may be induced. The pupil is commonly sluggish, showing a defective excitability of the nervous system, and, ultimately, there is amaurosis of the eye. The other senses are more or less impaired, or lost; the hearing, smelling, feeling, taste, and touch, are the last to go in these cases. The child is partially convulsed, and there is grinding of the teeth, and in some children liable to spasm, this is carried on to such a degree that the teeth are ground down to the gums. The locomotory powers are also impaired, and the child is unable to walk; the appetite is voracious, and there is a tendency to vomiting; change of posture excites giddiness, and produces sickness and vomiting. As the disease advances still more, and thus degrades the creature, diminishing the various senses, and the power of motion, it reaches the organic functions, and at length, the respiration and circulation fail, and the child dies. It is remarkable how these children with large heads live; how the system becomes accommodated to it. In a few cases that have come on gradually, where the shape of the head has yielded from the beginning, and continued to yield, it is remarkable how the intellect has been preserved, sometimes entirely, sometimes partially so. A very curious fact arises, that although hydrocephalus is generally a disease peculiar to children, it is not always confined to them, and cases are recorded of persons with this disease living to the age of 50 or 70. There is a curious case recorded of an hydrocephalous patient at the age of 32; the head was 33½ inches in circumference, 20½ inches from ear to ear, and 23 from the nose to the occiput. In this case the ossification was complete, so that no fontanelle of any size was left open, and although the patient was rather weak in intellect, he was by no means idiotic; but he was subject to epileptic convulsions, and he died in a state of coma. Heberden gives a case of a man with twelve ounces of serum on the brain, and ossification of the arteries, who experienced only a little giddiness till six weeks before his death. It is possible that the ossification of the arteries produced some change in the condition of the blood. Now with regard to the cause of hydrocephalus; it must be considered as the result of congenital formation, some disproportion or other between the parts of the head, and probably between the size of the veins and the arteries; something causing venous obstruction. It has been found in some cases of children who have died of hydrocephalus, that the veins are obstructed, and this would, you see, reduce this form of dropsy to the same category as the two other forms of dropsy arising from venous obstruction. Scrofula is commonly considered a cause of hydrocephalus. Blows on the head have been observed to be followed by it in some cases of the acute disease.

The treatment of this affection is in the case of congenital disease, of very little use, but where it occurs in early age, and is not congenital, it sometimes is curable. Golis seems to have had considerable success in the treatment of chronic hydrocephalus, having cured a great many cases by small doses of calomel repeated for a long time; a quarter of a grain to half a grain twice a day, using the stimulant mercurial ointment, and covering the head with a flannel cap. In six weeks of this treatment, he found the head diminished half an inch, or one inch. If no improvement took place in six weeks, then, in addition to the calomel treatment, he employed blisters or tartar-emetic ointment to the head, and even leeches in some cases, the diet being of a nutritious kind. I have cured cases myself in this way, exhibiting mercury, squill, and iodide of potassium internally, and using also the flannel cap. Dr. Gowe, of Middlesex Hospital, recommended a preparation of ten grains of mercury, a scruple of madder, and five grains of squills, rubbed up together and given three times a day for three weeks; then twice a day, and afterwards once a day. Compression of the head with bandages has been found serviceable in a few cases. The most signal success has arisen from puncture of the brain. There was a remarkable case in which it took place spontaneously: the patient fell on a nail, so that the back of the head was injured and perforated, and being tapped by this rough method, the fluid escaped and the child entirely recovered. In another case, the fluid burst out spontaneously, and temporary relief was given. Dr. Conquest, who appears to have had the greatest amount of success, has published an account of nineteen cases which he treated in this way, ten of which recovered; they were all children under nine years of age, and the quantity of fluid drawn away was from six to fifty-five ounces. The operation requires to be performed in some cases five times, and in others only once.

We now come to the subject of epilepsy which I can only just begin in this lecture. Epilepsy and convulsions occur in the course of other diseases. It may occur in the course of apoplexy as a prelude to paralysis, and in connexion with hydrocephalus. Convulsions may be produced by a temporary cause, in fact convulsions, and epilepsy, or the epileptic fit, are both essentially paroxysmal affections that occur for a short time, only they come on in paroxysms or fits, and in this case they are different from paralysis. Epilepsy may come on suddenly, or gradually; it does not come on and then cease, whereas convulsions occur in fits. Epilepsy is more a term given to a disease in which the fits come on again and again rapidly, and it may be said to bear the same relation to convulsions that asthma does to dyspnœa.'

The symptoms of an epileptic attack come on without any premonitory warning; the patient is sometimes suddenly seized with something which occasions him to utter a piercing scream, a yell of the most unearthly and appalling nature. The epileptic scream is not always present. There is a contraction of the muscles, a sort of tetanic convulsion, and rigidity; the eyes are distorted and there is strabismus; the face is altogether very much distorted, and becomes flushed from the excessive straining, and passes soon into a state of deathlike colour without becoming livid; then after a few seconds of this condition, convulsions ensue. In some cases, the convulsions are so violent as to cause serious injury; the jaws have been dislocated, the teeth broken, and the tongue bitten through; the appearance of the patient during the convulsion is most horrible: the eyes roll and squint hideously, and the features are horribly convulsed; the urine and fæces are involuntarily expelled; the breath is commonly affected, and becomes panting, and excited, and sometimes is accompanied by a sort of hissing, a hideous snorting noise, but not like the slow perfect stertorous breathing of apoplexy, being rather that arising from an extraordinary amount of contraction of the various muscles interfering with the proper motions of respiration. This state goes on for a longer or shorter time, and then there is a cessation, the patient taking a deep sigh as if recovering from violent exertion, and he recovers consciousness, sometimes suddenly and sometimes gradually, seeming not to have the slightest recollection of what has happened; and sometimes falls into a deep sleep. Sometimes there is an epileptic attack of the nervous kind, in which convulsions do not occur, but a loss of consciousness occurs, and a loss of power. The patient is suddenly seized with something that comes over him, and he becomes totally unconscious of what is passing around him. In still slighter cases, there is not a loss of consciousness, but a sudden disturbance of feeling whilst the person may be talking; his speech becomes interrupted, and in a few seconds this may pass off and he recovers. Epileptic patients subject to these attacks say it is like a cloud that comes over them, and they lose recollection and thought for a time; but there are no convulsions.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES—MORBID AND HEALTHY,

By Dr. Knox, F.R.S.E., F.R.C.S.E.,
Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

It is my present belief that, upon the whole, the capacity of the cranium of the white races must be somewhat greater than that of their darker brethren; but this is far from being proved, and as yet, as far as I know, measurements are against the theory. I shall, towards the conclusion of this lecture, give the measurement of a considerable number of Scotch heads; in the mean time, we shall proceed with the tabular views drawn up from an examination of the crania in the Phrenological Society.

Table IV,

Containing the absolute height of the cranium and face when placed on a horizontal surface, from the base to the vertex. (The numbers of the crania are marked in the column Race.) *The highest was just* 6 *in. and* 3-16*ths*; *the lowest* 5 *in. and* 3-16*ths.*

Blackfoot, 2	5 13-16th	5 11-16th	5 12-16th
Seminole, 2	6 3-	5 14-	6
Turk 1		..	6
Albanian 1		..	5 14-16th
Icelander		..	6

By height of square is simply meant, the greatest height attained by the vertex of the cranium when placed on a plane surface. It is not a measurement of much importance, but future enquirers may use it as an element in their calculations. Those attaining six inches and upwards are:

The English of Barbadoes	6	3-16th.
The Ashantee	6	1-16th.
The Swiss	6	
Phillipine Isles	6	
Seminole	6	
Turk	6	
Icelander	6	

Amongst those attaining five inches and upwards are:

The Black-foot Indian...... 5 12-16th.
Native of Vera Cruz ...... 5 10th.
Albanian .... 5 14th.
Chilian .... 5 13th.
Scotch.................... 5 9th.
Irish .... 5 8th.
Hindoo .... 5 7-16th.

From some subsequent measurements, I have reason to believe that the average height of the male Scotch head is considerably higher than the above; should it amount to six, which is not improbable, then it would possess an elevation of probably of a quarter of an inch over that of the Hindoo head; an important difference, no doubt, and yet scarcely adequate to the explaining why a handful of adventurers, whose doings have at times been sufficiently clumsy, should be able to hold in the most abject slavery a hundred millions of their darker brethen.

Table V. must be considered an important one; it embraces the whole range of the cerebral mass, and it exclusively.

TABLE V.

Tape measurement from the anterior margin of the foramen magnum occipitis to the root of the nasal spine of the frontal bone, over the vertex, longitudinally.

The lowest in the table is the head of the flat-head Indian, 14 6-16ths, but it may have belonged to a woman, the dimensions of whose crania in every way are considerably smaller than we find them in the male. These are the grand distinctions in crania—namely, sex and colour. At the close of the lecture I shall give another tabular view of a series of Scottish heads, distinguishing, in as far as we can, the male from the female. Already, from an examination of six male and one female, it seems to me that the average Teutonic head may be larger in most of its dimensions than those of any other race.

III. The differences observable in the skeleton of the head in mankind are referrible either to—1°, specialities as to race: or 2°, individual peculiarities which cannot be traced to any race in particular. Sexual differences exist, of course, in all the races; that is, the male head differs from the female apparently in every race. Of a few of these specialities and differences I shall now speak:—

1°. The crania of most mammals is probably symmetrical—cranium and face; but there is at least one exception to this, where a want of symmetry is "the law." There is a species of grampus in which the cranium is uniformly symmetrical; so it is also, to a certain extent, in the nerwhale. But the want of symmetry in the human cranium and face, exceedingly frequent in the human race, and perhaps most of all in the Scandinavian or Teutonic, is yet not regular; it is not a constant law; it may take place, or it may not, but at all events it belongs to no particular race.

2°. I have sometimes thought that a coarseness of fibre, and a looser texture of bone was observable in the dark races. The sutures also appear not so distinctly serrated; they run more in straight lines like harmonie, and there is less arching of the squamous suture generally; sometimes it is quite straight.

3°. The overlapping of the frontal by the parietal is exceedingly rare, and I have seen it only in the European; the overlapping, on the contrary, of the parietal by the occipital, and the extreme protrusion of the latter, is exceedingly common, but most of all in the fair races, and especially in the Saxon and Celtic. Indeed, it happens so rarely in the dark races, that for some time I doubted its occurrence.

4°. But of all the distinctions between race and race, the comparative difference in the size of the jaws is the most uniform, and the universal specific distinction. None of the fair races approach the dark in the vast size of the jaws; this begins to show itself very early, indeed soon after birth. It is a never-failing source of distinction when all others may fail.

5°. A long or short spheno-parietal suture is not peculiar to any race. It may be nearly wanting in the best formed European heads. The minute history of this suture, and its mode of formation, will fall to be described while speaking of the development of the sphenoid and temporal bones; it will then be found that the differences as to the spheno-parietal suture depend on the accidental development of one or two supernumerary bones at the angle of junction between the temporal, sphenoid, and parietal bones. These little bones overlap each other, and are squamous. As they unite to the temporal, or to the sphenoid, the spheno-parietal suture undergoes corresponding changes as to length; for should these supernumerary bones unite with the squamous plate of the temporal, and remain distinct from the sphenoid, then the spheno-parietal suture becomes very short, or may be wanting altogether; but when they unite with the sphenoid, and remain distinct from the temporal, the case is reversed. Thus, the presence or absence of this suture has nothing whatever to do with the general enlargement or diminution of the cranium. In fact, the whole matter resolves itself into one of an interchange of elements between the sphenoid and temporal bones, and a corresponding alteration of breadth, as one or other possesses itself of the supernumerary bones developed between them. These additional bones seem to be very interesting; they are repetitions of the squamous plate of the temporal on a small scale: pre-squamous bones.

6°. The races present no peculiarities in regard to the nasal and anterior palatine foramina; nor in the presence or absence of all traces of the inter-maxillary suture; nor in the development of those crests found so remarkably prominent on the surface of some crania. To these crests I have already alluded when describing the frontal bone; they form a system not understood by writers on mere human anatomy. They are disposed to become durable, or to bifurcate. One commences mesially on the external surface of the frontal bone, and running upwards, joins, by bifurcating, two on the parietal bones, which continue onwards towards the occipital. Another commences on each side at the external angular process of the frontal bone, and running upwards singly, or bifurcating, terminates by running on to the surface of the mastoid process of the temporal. But these crests, though forming remarkable approaches to what we find developed in the Oran and Chimpanzee, are not peculiar to any race; and the same may be said of the superciliary arches, whose development seem more connected with the generative organs than with the frontal sinuses. Ivory deposits may be found on any crania, nor is general strength of cranium peculiar to any race; nor persistance of the frontal or other sutures; nor are there any peculiar supernumerary bones.

PATHOLOGY OF EXPECTORATION.

By S. WRIGHT, M.D., Edin., F.S.A.
Physician to the Birmingham General Dispensary, formerly Senior President of the Royal Medical and Royal Physical Societies of Edinburgh, &c, &c.

(Continued from page 53)

The secretion of thin mucous sputum may be *intermittent* or *remittent*, as usually happens in symptomatic affections of the respiratory organs; or *persistent*, as in their idiopathic disorders. It may be either casual or critical. No duration can be assigned to the discharge, for it will sometimes terminate in a few days; and again, it will continue for years. Its quantity is equally variable; at one time it amounts to only a few ounces in twenty four hours, and at another time, to many pints. It is generally expectorated alone, but in some varieties of bronchial irritation and catarrh, it is seen to contain masses or pellets of thick mucous or albuminous sputum, which float separately in it, and never intermingle or dissolve It may subside gradually, with or without an increase of density; or, as not unfrequently happens, it may cease suddenly and without any obvious cause. In some rare cases, patients die of the disease which it accompanies, and the expectoration will continue until within a few days or few hours of the period of dissolution. (1)

Local Symptoms and Physical Signs.—This form of expectoration is often exceedingly troublesome. but it is seldom indicative of danger. When the quantity discharged is very considerable, emaciation is a necessary consequence. It is attended with a tickling cough, of irregular, and occasional or incessant recurrence. There is generally a sense of irritation, or of slight smarting, rarely of acute pain, in the fauces, and along the course of the trachea and larger bronchi; occasional dyspnœa, and irregular respiration, which are easily and instantly increased by sudden emotions, and by active or violent exertion.

Percussion usually elicits natural sounds, or at most it only discovers slight dulness in the lower portions of the lungs. The respiratory sounds are various, and chiefly remarkable in the direction of the larger bronchi. They are the sibilant sonorous, or mucous *râles*; but often there is no perceptible deviation from the natural murmur. In the catarrhal affections in which pellets of thick mucus are singly discharged along with the profuse thin secretion, it sometimes happens that these tough masses will obstruct one or other of

(1) These cases are chiefly organic diseases of the heart, obstructing free circulation through the lungs, and giving rise to local nervous irritation of various degrees of intensity.

the air tubes, and consequently suspend the respiratory action in the part of the lungs to which it leads. (2) But if percussion be carefully employed, it will show that the vesicular structure is unimpaired. It very rarely happens during the expectoration of thin mucous sputum, that interruption to the free passage of air through any of the bronchial tubes arises from thickening or tumefaction of their lining membrane, though as we shall hereafter see, this pathological condition is not uncommon in chest diseases attended with other forms of sputa.

Pathology.—The expectoration of thin mucous sputum is usually consequent upon a relaxed or an irritated state of the mucous membrane lining the trachea and bronchi. It may be confined to the former, or may extend partially or entirely through the latter. It seldom arises from inflammation, and never but when such inflammation is of very slight intensity, and occurs in debilitated or naturally feeble subjects. When it proceeds from sympathetic irritation, forms of which are best seen in nervous and chlorotic females, the tracheal or bronchial membrane rarely presents any abnormal aspect; in other cases, in which the circulation is more implicated, it will be very slightly injected in patches or streaks. I have never observed the injection to be uniform, or of large extent. The most common appearance is a pale watery tumefaction of the membrane of the trachea and larger bronchi, and mucous exudation into the smaller branches. The tissue is not more tender than usual, but it feels soft, or pits under pressure, and exudes a little limpid fluid.

Treatment.—This will of course depend upon the nature of the disease or disorder which the expectoration of thin mucous sputum accompanies. In nervous, hysterical, and melancholic cases, a full dose of opium, or ether, or camphor, or any other stimulant and narcotic, will often either cut short the attack, or considerably lessen its severity. In debilitated and chlorotic subjects, there is nothing better than quinine or sesquichloride of iron, with generous living, walking exercise, and the shower-bath, or sponging the throat and chest with cold salt and water. When stronger local counter-irritation is necessary, it is best obtained by the application of tincture of iodine, tartar emetic ointment, or croton oil. Single blistering is not permanent enough to be useful, and if a perpetual blister be employed, it creates more irritation and pain than are equivalent to the good it does. Aloetic aperients will be found of excellent service.

When the expectoration depends upon some irritation, *sui generis*, of the tracheal or bronchial mucous membrane, infusion of buchu, with hemlock, hyoscyamus, or prussic acid, is an admirable remedy. I have known much benefit follow the respiration of the vapour of hot water, containing camomile flowers, or bruised poppy heads. A narcotic sedative bolus, with a little blue pill may be taken at bed-time. The following formulæ I have employed with much advantage.

℞ Extracti Papav. Conii Albi gr. iss.—iii.

Camphoræ aa. gr. ii.—iv.
Pil. Hydrargyri gr. ss.

Misce. Fiat bolus, hora somni capiendus.

Care should always be observed to maintain a due action of the kidneys and bowels. Derivatives applied to the legs and feet are useful adjuncts.

We must be mindful, however, to discriminate well the cases which come under our treatment. In some instances, as I have already remarked, it is more desirable to encourage than to check the discharge.

THIN MUCOUS SPUTUM. *b. Acrid.*—This form of expectoration, though to a certain extent resembling that which we have just considered, yet presents so many important points of difference and of pathological relation, as to require for it a separate denomination and notice.

Appearance and Qualities.—In external aspect, and specific gravity, this sputum differs little from the "insipid" variety. It is sometimes almost tasteless, but it is usually complained of as being sour, salt, biting, or bitter. Its reaction upon test-paper is either neutral or acid. Its saline constituent is chiefly muriate of soda, in variable proportion. It contains less mucus, as a rule, than the insipid sputum; albumen is occasionally present, and in severe cases, pus may be seen in it.

Pathognomonic Relations.—This form of expectoration chiefly occurs in inflammatory affections of a subacute and unhealthy kind, attacking the respiratory organs. Bronchial and tracheal irritation, also, which in a healthy subject will give rise to the secretion of insipid sputum, in a scrofulous, scorbutic, or otherwise depraved constitution, will excite the acrid variety. It is apt to prevail in some forms of catarrh and influenza, which are modified either by individual peculiarities, or by the circumstances of climate, season, locality, temperature, &c. Van Swieten (3) says, that in some catarrhs this matter is so acrid as to cause erosion and ulceration of the lungs. "Interim tamen, si materies catarrhi acrior fuerit, vel valida et diuterna tussis nimis quassaverit, pulmonem, quandoque pulmo eroditur, ulceratus, et sic ex catarrho phthisis pulmonalis sequitur." In the early stages of consumption it is sometimes met with, and in more advanced phthisis it will often alternate with the expectoration of purulent, or muco-albuminous sputum. It commonly attends the eruptive diseases of cachectic children, and will frequently excoriate the parts which it touches. I have seen even the backs of the hands completely abraded by it. (4)

I have repeatedly observed this kind of sputum in the bronchial affections of dissipated subjects, and of others who have suffered from wanton mercurialization, or from constitutional syphilitic ravages. In young people (especially scrofulous) it is apt to occur as a sequela of mercurial treatment.

The expectoration of this sputum is less liable than that of the former variety to intermit or to remit: it is usually persistent, but not for any great length of time, seldom indeed beyond a few weeks. It may terminate suddenly, or may be succeeded by a discharge of "insipid," "muco-albuminous," or "muco-purulent" sputum perhaps streaked with blood. It is rarely a critical expectoration, and its quantity is never considerable.

Local Symptoms and Physical Signs.—This form of expectoration is invariably accompanied by a teazing, and often by a painful cough. In severe cases it is agonizing, and is complained of as being "like tearing the throat in pieces," "or searing it with a hot iron." There is a sense of heat and dryness in the air passages, and occasionally of infarction in the chest. Percussion often elicits duller sounds than natural, especially in the more dependant parts of the lungs. The breath sounds are generally, at the commencement, a sonorous *rale*, in the larger bronchi, with wheezing expiration; in a more advanced stage, we have a sibilant *rale*, with diminished vesicular murmur; and at the termination, there is often a distinct mucous or crackling *rale*. When the larynx is affected, the voice is more or less hoarse or shrill, and the inspiratory sounds are hissing or grating.

The tongue is generally red, with inflamed and elevated papillæ, and the mucous membrane of the mouth and fauces is of a bright scarlet colour. In severe and protracted cases, the tongue and adjacent parts will become excoriated, aphthous or ulcerous. There is usually distressing thirst and much sympathetic fever.

Pathology.—Thin acrid mucous sputum, is the offspring of irritation and inflammation, more or less severe, affecting the lining membrane of the air passages. This inflammation is modified and marked, either by an unhealthy condition of the subjects affected, or by adventitious extrinsic circumstances. The *post-mortem* appearances are always more or less inflammatory—a uniform redness, limited, or diffused throughout the extent of the trachea and larger bronchi; circular or streaky patches of vascularity; and ulceration, bounded by areolæ of various hues, are the most common pathological features. Small irregular spots of ulceration are often found in the larynx. The mucous membrane is sometimes tumid, easily lacerable, and dotted with ecchymoses; at other times it will be found dry, shrivelled, and friable to the touch. The larger bronchi are either contracted irregularly, and flattened, or are uniformly diminished in calibre. The smaller sub-divisions are for the most part obliterated, or contain a mucous exudation, colourless or sanguinolent.

Treatment.—In severe cases, the treatment ought to be purely antiphlogistic, but should rather consist in the exhibition of salines, diaphoretics, and sedatives, than in blood-letting. The local abstraction of blood, by leeches or cupping, is often advantageous, but it very rarely happens that the patients are benefitted by general bleeding. I have more than once, in scrofulous subject, seen the disease aggravated by it. We must be careful also, of the administration of mercury; if there be much constitutional debility, or cachexia, it should be withheld. Antimonials, with alkalies, hemlock, prussic acid, and camphor, are the best remedies. Blisters, often do good, but they are apt to cause sloughing. Warm baths are beneficial, as is also sponging the throat and chest with hot water containing common salt or mustard. The patient should if possible inhabit a uniform temperature of suitable warmth, and should frequently respire the vapour of hot water, holding in suspension, camomiles, or bruised poppy-heads. It is desirable, as early as possible after the reduction of the inflammatory symptoms, to commence a tonic plan of treatment.

(To be continued.)

PROGRESS OF FRENCH SCIENCE.

FROM OUR OWN CORRESPONDENT.

Paris, April 10th, 1845.

Academy of Sciences; Sitting of the 7th of April. M. E. de Beaumont in the chair.—M. Flourens presented the second edition of his "Histoire des Travaux de Cuvier." This work may be considered as the first part of the "Histoire des Travaux et des Idées de Buffon," for, as the distinguished perpetual secretary observes, "the history of one of these *savans* can only be considered complete by adding that of the other." It contains,—I, The eulogium on Cuvier, pronounced at the public sitting of the Academy of Sciences on the 29th December, 1834.—II, A historical notice of Cuvier's publications: 1° in zoology; 2° in comparative anatomy; 3° on fossil bones; 4° on comparative anatomy applied to natural history in a general and philosophical point of view.—III, Finally, it is closed by a list of the numerous works published by Cuvier.

On the Theory of Vision.—Mr. Stevenson addressed a letter on this subject, in which he remarks, that if the theory he combats had originated from M. Arago, he would have written to the illustrious professor himself, and not to the Academy; but as it is supported by all the professors in London, Berlin, and wherever science is cultivated, as well as in Paris, his communication tended only to attack the theory, not to make the least allusion to that distinguished *savant.*

On a New Classification of Organic Compounds, by M. Chs. Gerhardt, presented by Professor Dumas.—In a preceding paper, the author stated that in the union of a compound with a simple substance the latter was not merely displaced, but that reaction took place constantly, and in such a way that an element (hydrogen) of one of the sub-

(2) These masses of mucus will sometimes obstruct even the trachea, and produce asphyxia and death. I met with a remarkable case of this kind only a few days ago, in the person of a female, a patient of my friend Mr. Amphlett, of this town. The woman had been for some time suffering under a mild form of bronchitis; but in one of the paroxysms of coughing, she suddenly became unusually agitated and convulsed, threw her head back, and died almost instantly. The cause of death was a little "muco-albuminous" substance plugging the opening of the glottis.

(3) Comment. in Boerhaav. p. 2.

(4) Hoffman says that in schirrus of the lungs, the expectoration is sometimes very acrid—"sub qua ardens sensus os, fauces, et asperam arteriam obsidens, ad cordis usque scrobiculum propagabatur, ac cuticulam oris internam excoriabat." Op. Om. Phys-Med. Tom. 4. p. 117.

stances was united to one of the elements (oxygen) of the other, so as to form a compound (water) which was eliminated, whilst the remaining elements were combined. This law, which may be called the "law of residua," is equally applicable to all nitrogenized bodies, amides, ethers, salts, &c. According to this law, ammonia—which is a hydrogenated compound—combines with the oxygen or chlorine (bromine, iodine) of the organic substances to form either H^2O or $H\,Cl$. which is eliminated; the residuum of the ammonia which remains in combination with that of the organic substance, may be represented by NH or NH^2, and if we indicate the two organic compounds by AO and ACl., the following formulas may be established:—$AO + NH\,H^2 = H^2O + ANH$, and $ACl. + NH^2H = HCl. + ANH^2$. Alcohol and analogous substances, like ammonia, act by means of their hydrogen on oxygenated or chloruretted compounds, giving rise to an elimination of H^2O or $H\,Cl.$, the remaining elements constituting ethers. When engaged in the study of these substances, the author obtained two anilides in decomposing the oxalate of aniline by heat in a sand bath; at a few degrees above 212° F it boils, and disengages water, carbonic acid gas, and aniline, when the temperature is raised to 320° F, or 356° F, oxyde of carbon is disengaged, and the heat need not be augmented; as soon as this last mentioned gas ceases to escape, a liquid residuum is obtained, sometimes limpid, sometimes more or less coloured red, according as the salt employed is more or less pure; this soon after hardens into a mass of the consistency of butter, containing beautiful crystals, and which is a mixture of two new compounds—oxanilide and formanilide. Oxanilide:—by adding boiling alcohol to the residuum, the formanilide is dissolved, and the oxanilide left in crystals, like small spangles, of a pearly white, somewhat similar to boric acid; melts at 473° F, and on cooling forms a radiated mass; boils at 608° F; distils without being decomposed; insoluble in water, ether, and cold alcohol; slightly soluble in boiling alcohol; undecomposed by boiling solutions of alcalies or acids; formula $C^4\,H^{12}\,N^2\,O^2$. Formanilide:—the alcoholic solution obtained, as before stated, must be heated so as to cause the alcohol to evaporate; the residuum must then be dissolved in water in order to remove the small quantity of red or brown matter formed by the action of the air; the aqueous solution is then allowed to evaporate spontaneously, and the formanilide is slowly deposited in small flat lance-like rectangular prisms, sometimes an inch in length; soluble in water, especially when hot; still more so in alcohol; the aqueous solution is slightly bitter, without any action on test paper; melts at about 115° F, but when liquid, the temperature may be carried much lower without its concreting, if care be taken not to stir it, for on so doing, it becomes solid instantaneously; cold diluted acids and solutions of alcalies have no immediate effect, but decompose it gradually; when hot, the decomposition takes place with greater rapidity. Formula, $C^7\,H^7\,NO$.

On Diabetes Mellitus or Glucosuria, by Dr. Bouchardat.—First memoir. The author in this memoir establishes from numerous facts the *rapport* between the proportion of fecula taken by diabetic individuals and the sugar contained in their urine, and recommends as the most appropriate remedies, alcoholic liquids and fatty substances.

On the Splanchnic System of Nerves. Memoir read by J. M. Bourgery, D.M.P.—From his researches the author concludes: 1° That the so long contested opinion of the anastomosis from one side to the other of the cephalic extremity of the sympathetic nerve is solved affirmatively, but with a modification in their relation as interesting to physiologists as to anatomists.; 2° That instead of a single cephalic cord, there are two, a vertebral and a carotidean, which offer five modes of termination, to which are associated the cephalic nerves and the gland constituting the pituitary gland. In this mysterious anatomical conflict of the different nervous organs, grouped together in the central sphenoidal region of the base of the skull, their affinities, as far as can be judged, are equally numerous, whether they are studied separately, or in the union they form with each other by means of their anastomosis; 3° That considered separately—(*a*)—the cephalic or supra-sphenoidal pituitary gland seems to be the organ by means of which union takes place, that is to say, between the pyschological and instinctive nervous centres and the cephalic nerves, these forming the principal mode of communication with the great sympathetic, which connects all the splanchnic nervous system. Besides the size of the pituitary gland being more considerable in the animal than in man, and the number of branches which this gland receives from the two lateral portions of the sympathetic, seems to prove that it belongs especially to the nervous system of organic life, and constitutes the central gangliomary cephalic mass—(*b*)—the sympathetic varies in its four modes of termination; the principal, or at least the most voluminous and which seems to be the union of the sphlanchnic nervous system with the encephalon, is effected in the pituitary gland. That which forms the two median plexuses constitutes the anastomosis or the outer union of the two lateral halves of the sympathetic. The apparent termination on the cerebral arteries may be considered rather as an origin, and is nothing but the visceral nervous system of the encephalon, united in its centre, like all the extra-visceral plexuses, by a central gland, which is here the pituitary, but like these plexuses, accompany the arteries with the branches of the sympathetic. The last termination of the sympathetic is its anastomosis with the extremities of the cephalic nerves.—(*c*) As to the cephalic nerves, the four last have as many anastomoses with the superior cervical ganglia as with the temporo-carotidean ganglia. The facial and the acoustic anastomose with the branches of these ganglia The plexus of the six first cephalic ganglia present as numerous anastomoses with the pituitary gland as with the sympathetic. Although the six cephalic gangliomary nerves, situated beside the *sinus cavernosus*, contribute to the formation of a common plexus, it is principally the trigeminus which produces this, it being the focus where the numerous grey filaments unite with each other. In this respect this nerve seems to be an annex to the sympathetic, intermediate between the two nervous systems (ganglionic and cerebro-spinal) and justifies by its structure as well as by its anatomical relations, the denomination of *small sympathetic*, given to it by some physiologists; 4° That finally studied together, in their union, the three varieties of nervous organs situated in the supra-sphenoidal region offer seven species of anastomosis.—(*a*) On the same side from before backwards, the union, by means of the communicans, of the carotid and vertebral nervous system—(*b*) from one side to the other, the six others take place on the mesial line.

On Scrophula, or Remarks on a Work of Dr. Lugol, "Recherches et Observations sur les Causes des Maladies Scrofuleuses." By Dr. Vergnies.—The author considers that the primitive seat of this disease is not in the glands; that an hereditary taint alone does not produce the affection; that the vital powers oppressed by the morbific principle remain always unaffected, and sometimes combat the disease advantageously without the help of medicine.

Dr. Fauche writes to state, that an artificial arm in every respect equal to that of M. Van Petersson was invented by M. Laurent, one of his ancestors, in the reign of Louis XV.

MM. Bouchardat and Sandras in reply to the reclamation of M. Mialhe, refer him to the *Compte Rendu* of the 15th April, 1844, which contains their ideas, researches, and theories on the action of alcalies on saccharine and amyloid substances, and their memoir, read at the sitting of the 21st January; they likewise announce, that they are pursuing their researches on digestion, and will communicate the result to the academy.

Professor Orfila addressed a letter, stating that the report presented by the *experts* named to examine the *rob*, mentioned in MM. Flandin and Danger's memoir, never asserted that it contained mercury, that they knew that the apparatus invented by Smithson often failed, and that the precautions described by him many years ago are the same as those indicated by the authors of the memoir.

M. Barse addressed a letter on the same subject, in which, after combating the various opinions emitted by MM. Danger and Flandin, he concludes by claiming the priority as to the carbonisation of animal matter with sulphuric acid.

Dr. Guylon sent some instruments of lithotrity invented by him, and Dr. Morel Lavallée a memoir on the physiology of respiration, both for the Monthyon prize.

Academy of Medicine. Sitting of the 9th April: M. Caventou in the chair.

Considerations on Mental Alienation in a Psychological point of view, by F. Dubois d'Amiens, D. M.—According to the author, the study of mental alienation cannot, without inconvenience, be separated from psychology. It is by a perfect knowledge of the faculties of the mind, that the nature and causes of dementia can be elucidated. It is for this reason that Maine du Biran, at the demand of Royer Collard, instituted a course of study of mental diseases founded on psychology; dementia is but a long dream, in which the divine principle, the *moi*, deprived of its power and free will, can neither escape nor overcome the false perceptions. All the intellectual lesions indicate the existence of an organic affection of the central nervous mass, which may or may not be appreciable, but which must be admitted in order to avoid being bewildered by a host of hypotheses. Dr. Rochoux, after stating that he coincided with the author of the memoir on the last opinion emitted, continues thus, "When I heard the famous *moi* announced, I expected it to be clearly and evidently demonstrated. Vain hope! Moreover Maine du Biran, quoted by Dr. Dubois, was not more fortunate. As to Royer Collard, his favourite argument to prove the existence of a spiritual principle was: 'All takes place in the organism except the will.' Now, if the will is a proof of a spiritual principle, is there a creature so highly endowed as the ass. As to the anathema pronounced against the principles of sensualists and this conclusion, 'all the varieties of mental alienation are dependent on an organic lesion, I cannot see on what grounds it can be founded." Dr. F. Dubois, in reply, said that the contradiction was more apparent than real, and that he was a sensualist, inasmuch as he considered the senses necessary for the perception of surrounding objects. Dr. Virey does not consider it possible to explain partial delirium by organic lesions. Dr. F. Dubois said, that partial delirium is not very common, for on examining the patient attentively, the intellect is found more seriously affected. But it may be asked, where is the lesion in these cases? This it is impossible to answer; but by *post-mortem* examinations, this question will at length be elucidated. Dr Ferrus: "I consider dementia to be always dependent on an organic lesion, and am of the same opinion with respect to cases in which the intellect is obtuse, since every functional, supposes the existence of an organic, lesion. The functions of the brain are; feeling, perception, judgment—in short, intelligence. Now, when one or more of the intellectual faculties are changed—perverted—we must necessarily conclude that an organic lesion exists. The domain of pathology is the organism, and the philosophy of medicine is founded on the observation of facts, independent of the primary cause; it is by the functional disturbance that we study diseases, and it is by this that we act on the individual by what we call moral treatment, and that we employ the remedies which are considered as modifying diseased organs. As to the opinion that the soul sleeps in idiots, I consider it quite erroneous, since the idiot sees, walks, hears with difficulty, and, indeed, in confirmed idiotcy, the patient would die of hunger if he were not fed. Dr. Castel thinks that alienation may be produced by a moral as well as a physical cause. Professor Gerdy considers it highly important not to confound faculty and function. After some further remarks from Drs. Rochoux, Ferrus and Dubois d'Amiens the discussion was closed.

On Tubercular Affections of the Lungs and the

Bronchial Glands.—The following cases, which occurred in the wards of Professor Trousseau at Necker's Hospital, prove how difficult it is to discover the presence, or suspect the development, of these diseases in children, hidden as they are under the appearance of the most perfect health. Thus, children previously quite well, are seized with pneumonia, which ends fatally, and on the *post-mortem* examination, the bronchial glands are found to be completely tubercular. That this is the case, clinical and pathological observation daily show; it cannot, therefore be denied, that tubercles may develop themselves with extraordinary rapidity in children, and, as this occurs very often, it may be concluded that this affection is at its maximum of frequency in children, and not in adults, as is generally supposed.

Case 1st,—Vomiting, Meningitis, Convulsions, Tubercles.—Elizabeth Pauline Godard, æt. 10 months, vaccinated when two months old, generally enjoys good health; never had convulsions, no teeth; has coughed for the last month; cough increased in intensity within the last month, but not in fits; a short time before her admission (28th Feb. 1845), she was affected with diarrhœa, followed by constipation and frequent vomiting, not produced by the fits of coughing. No fever in the morning, but the skin is very hot towards evening and during the night (℞ Magnes. gr. iv. ex. aqua :—enema.)—March 2nd. Cough still continues, and by its intensity produces vomiting, not only of the food taken, but likewise of a ropy liquid; pulse frequent; heat of skin normal. ℞. Magnes gr. viij.)—3rd. Vomiting persists, but less violent, bowels confined, slight fever during the night. (℞ Calomelan. gr. j. pulv. jalap. gr. vj. pulvis statim sumendus.)—4th. Medicine has operated; abundant vomiting, produced by the cough, which does not, however, come on by fits, as in pertussis —(pastill. calomelan. No. 1.)—5th. Abundant vomiting, fever still the same; one evacuation; during the night awoke screaming, as if frightened, and, contrary to her custom, remained all day in a semi-comatose state—repet. pastill.—6th. During the night the child woke up frequently, screaming aloud; quiet in the morning; uncertainty in the looks; left eye apparently larger than its fellow; loud moans; from time to time the eyes stare, the pupils are directed upwards, and then the little patient remains perfectly motionless; slight convulsive motion in the muscles of the face, and feeble contractions of the fingers, as if *subsultus tendinum* existed; pulse unequal, 100; hitherto she had screamed violently when examined; to-day, on the contrary, seemed quite indifferent; takes the breast with avidity; tongue moist, foul at its base; nausea and vomiting still persisted; constipation; urine abundant but thick and highly scented. ℞ Calomel gr. j. sacchar. alb. ℈ij. ft. pulv. No. xij. quarum sumat j. quaque secunda hora. ℞ Rad. valerian. ʒj. aq. puræ Oj. pro enemate. At 11 A.M. the child was seized with intermittent convulsions, during which she remained in a comatose state; during the fits the following symptoms were observed:—tetanic rigidity and torsion of the limbs and of the neck; eyes staring; strabismus; skin cold, and of a violet hue; pulse imperceptible. ℞ Moschi gr. j. aq. distill. melis. off. ℥j. syrup. aurant. ʒv. syrup. ether. ʒj. pro potione.—7th. The symptoms persisted and death took place at one P.M. Autopsy 36 hours after death. *Brain.*—Meninges colourless; pia mater infiltrated with a considerable quantity of transparent serosity; no traces of a fibrinous secretion; small white firm granulations evidently not of recent formation, on the upper surface of the right hemisphere; on the left there was likewise a granulation, but it was so minute that it was discovered with the utmost difficulty; considerable quantity of transparent serum in the ventricles, at the base of the brain, and in the theca vertebralis; no abnormal coloration or *ramollissement* of the grey or white substance. *Lungs*, full of small granular tubercles; a large tubercle existed in the nascent state, near the surface of one of the lobes affected with pneumonia; granulations on the pleura; no traces of pleuritis; tubercles in the bronchial glands. *Abdomen.* Tubercles in the mesenteric glands, spleen, and liver; stomach in its normal condition.

Case 2nd.—Convulsions, Pneumonia, Tubercles.—Edward D—, ætat. 15 months, general health good, weaned at twelve months; vaccinated; had seven teeth, four upper incisors, two lower incisors, one upper molar. On the 2nd of January, during a visit the mother made to another patient in the hospital, the child was taken with a convulsive fit, which lasted an hour, and yielded only to the administration of a draught containing ether, and sinapisms to the lower limbs, and was followed by vomiting and slight diarrhœa. The child while in the hospital slept badly, woke frequently by starts; skin hot during the night; pulse at 150; cough. These symptoms yielded to gentle laxatives and an appropriate diet, and the mother and child left the hospital on the 13th of January. About the 17th or 18th, the little patient was seized with violent fever and dyspnœa; the mother, however, did not come to Necker, though she confessed that her child appeared to be very ill, until the 3rd of February, when the following symptoms were observed:—dyspnœa intense; face not thinner than usual; right cheek red; the remainder of the face and the lips livid; pulse very frequent, 176; skin hot; cough; superficial ulcerations on the lips; gums swollen; auscultation indicated the existence of a mucous *râle* in all the posterior portions of the lungs, mixed with a slight sub-crepitant rhonchus during deep inspirations; opposite the two fossæ infra-spinatæ the expiration was harsh, as if it formed the first degree of the bronchial inspiration; hands and feet affected with œdema. A leech was applied to each knee; the tail of one of them, when nearly full of blood, was cut off, and it bled for an hour and a half ere it fell; poultices were then applied over the leech bites; and a blister put on between the shoulders. 4th. Amelioration; breathing still frequent but much easier; colour of the skin normal; no fever; pulse 170; œdema of the feet less; pneumonia furrow not so deep as on the preceding day; sub-crepitant rhonchus still perceptible, more so on the left than on the right side; expiration not so harsh; diarrhœa, which existed from the commencement of the disease, was somewhat less; urine not albuminous. ℞ Looch. alb.(1) ℥vj., oxyd. antim. alb. gr. x. M. ft. mist. tertia pars 8vo. quâque horâ. As diet, fæcula cooked in water, and properly sweetened, and a little milk. 5th. Dyspnœa greater; face violet; no fever; pulse 144; tongue red; lips *ut antea*; no bronchial respiration; small mucous rhonchus; very slight sub-crepitant *rale*. A leech to be applied to the knee; repet. haustus; no food. 6th. At two a.m. the little patient was seized with convulsive movements; at the morning visit they still persisted; face pale and slightly tumefied; eyes turned upwards and slightly injected; pupils very dilated; cataleptic rigidity of the extremities; breathing difficult, more like that observed in epilepsy than in pneumonia, pulse frequent, small, hardly perceptible, 204; the child refuses to drink. ℞ Aq. distill. meliss. off. ℥j., syrup. flor. aurant. ʒv., moschi gr. j., tinct. belladon. gtt. ij. M. ft. mistura; cochl. min.qq. horâ sumend. Frictions on the limbs and thorax with baume tranquille ʒij. (2) 7th. The convulsions continued without interruption until four p.m. on the preceding afternoon, and then ceased; the child, however, did not come to his right senses before this morning; eyes still turned upwards; screams from time to time; dyspnœa; skin very hot; pulse very frequent, 176; sub-crepitant ronchus; no bronchial respiration; carphalogia on the left side. Repet. mistura, et frictiones; pro potu infus. tiliæ Europ. cum fol. aurant. 8th. The child seems better; eyes still fixed; carphalogia; insomnia; now and then subsultus tendinum; no convulsions; dysphagia; dyspnœa less violent; pulse not so frequent; skin cooler; sub-crepitant rhonchus still intense, though somewhat diminished; when touched, the child cries, without weeping; slight nausea, no vomiting; constipation; left pupil much more dilated than the right. Repet. looch ut antea. 9th. No convulsions; pulse not so frequent; pupils equally dilated; two blackish stools; sub-crepitant rhonchus; bronchial respiration at the base of the right lung, apparently produced by effusion, rather than a modification of the structure of the parenchyma of the lung. Repet. looch et potus. 10th. No convulsions; considerable agitation; dyspnœa great; cough frequent, by fits; mouth dry; thirst pulse 164; skin warm; when the child is quiet its eyes are turned upwards; but while asleep the lids are completely closed; while the agitation lasted, a slight sonorous rhonchus only could be heard; no bronchial respiration, nor dullness; pupils equally dilated. Rep. looch cum tinct. belladon. gtt. j. 11th. During the night, the left leg and the right arm were agitated convulsively; pulse 150, feeble, irregular; slight nausea; no vomiting; two stools; in other respects as before. Repet. looch. cum. tinct. belladon. gtt. ij. 12th. pulse very feeble, 160; no fever; right hand and leg œdematous, almost incapable of performing any voluntary motions, and when raised, fall like an inert body; eyes turned upwards and half closed; a *bruit* amounting almost to ægophony at the base of both lungs; bronchial respiration on the right side from the scapula downwards; several liquid stools. 13th. at one p.m. The convulsions recommenced, and presented a tonic character; opisthotonos; these symptoms persisted until six p.m., when the child died. *Autopsy*, thirty-six hours after. *Thorax.* Bronchial glands hypertrophied; some changed entirely into a tubercular mass, others only partly degenerated; pulmonary lobes adherent to each other; on the left side, pneumonia occupying all the inferior lobe, with the exception of a lobule here and there; the aspect of the parenchyma was not granular, but the cut surface presented the varieties of colour so common in infantile pneumonia; at the posterior and inferior portion of the upper lobe, a few lobules were affected with pneumonia: on the right side, the inferior lobe was not so inflamed as on the opposite side; the greater part of the middle lobe healthy; the upper lobe presented posteriorly and inferiorly an indurated mass containing small tubercles in the nascent state, and the pleura covering this spot offered numerous granulations. Other organs in their normal state.

Case 3rd.—Pertussis, pneumonia, tubercles. Albertine Thaler, ætat. seventeen months, entered the hospital on account of a slight enteritis, which soon yielded to an appropriate treatment, but when about leaving, she was taken with fever, cough, and lachrymation, which led to the supposition that rubeola was about to appear; this, however, proved not to be the case, and as the fever no longer existed, the child left, still coughing. About a week after, the cough became paroxysmal, and the fits increased in number and intensity, so much so that in twenty-four hours before her return to the hospital, she had had twelve during the day, and eleven during the night. The face and eyes are slightly œdematous, respiration somewhat more rapid, but no dyspnœa; no fever; pulse frequent, 160; abundant mucous and sibilant *rales*; as is customary in pertussis, the paroxysms are followed by vomiting of a ropy liquid and sometimes of food.—℞ Muc. gum. acac. ℥iv; syrup. simp. ʒvj; aq. distill. flor. aurant. ʒj; ammon. gtt. ij; tinct. belladon. gtt. ij. M. ft. mistura cujus sumat cochl. magn. q.q. secunda hôra.—Feb. 12th, Nine fits of coughing during the day, and thirteen during the night, each followed by vomiting; pulse not quite so frequent; cont. mist. 13th, thirteen paroxysms during the day, and twelve during the night; dyspnœa, fever, vomiting, mucous rhonchus; pulse feeble, 160. Emplastr. cantharid. region. thorac. posterior.—℞ Looch, ℥iv, kerm. min. gr. ij, haustus coch. magn. q.q. secunda hora sumend. 14th, amelioration; five paroxysms during the day, and four during the night; dyspnœa not so great; pulse 152; no fever; no vomiting produced by the

(1) *Looch blanc*(white looch) is composed of sweet and bitter almonds, almond oil, gum tragacanth, sugar and water.

(2) *Baume tranquille*, ℞ Folior. belladon., fol. hyosc., fol. solan. nig., fol. nicotian. tabac., fol. datur. stramon, papaver. capsul. aa. ℥iv., summit. absinth. off., summit. hyssopi., summit. lavand., summit. origan. majoran., summit. menth. aquat., summit. menth. virid., summit. hyperic. perforat., summit. rutæ. graveol., summit. thym. vulgar., flor. rosmarin. off., flor. samb. nig., aa. ℥j., ol. olivæ, lbij.—(Codex Francais.)

kermes; no diarrhœa; repet. mist. 15th, nine paroxysms during the day, and seven during the night; face pale; respiration frequent; abdomen slightly tympanitic; skin hot; pulse very frequent and small, 160; sub-crepitant *rale*; two leeches to the knees; cont. medic. 16th, pulse frequent; skin hot; four stools; paroxysms less intense; sub-crepitant *rale*; repet. 17th, fourteen slight paroxysms during the day and night; skin very hot; pulse, 160; face pale; respiration easy; abdomen slightly tumefied; bronchial respiration; nine stools; repet. mist. sine kermes. 18th, paroxysms continue, those during the day (seven) more intense than those during the night (five); pulse 150; less dyspnœa; respiration still frequent; features more natural; skin not so hot; slight bronchial respiration at the angles of the scapula; less sub-crepitant rhonchus; contin. medicam. 19th, pulse 168; skin hot; dyspnœa; sub-crepitant rhonchus increased; respiratory murmur heard with difficulty; two stools; sixteen paroxysms.—℞ Aq. distill. ℥iiiss, antim. tart. gr. ij. Mist. tertia pars 4ta qq. hora sumend. 20th, vomited several times after the administration of the medicine; four stools; pulse 176; no fever; fourteen paroxysms; slight dyspnœa; agitation, but no convulsions; death at two p m. —Autopsy thirty hours after. Thorax. Bronchial glands tumefied and almost entirely tubercular; hepatization of nearly the whole inferior lobes of both lungs; the various tints of these lobes and the normal condition of some indicated that the pneumonia was lobular; no tubercles in the lungs. The middle lobe of the right lung was partly affected with pneumonia; some inflammatory spots here and there in the upper lobes; no tubercles in either.

Case 4th.—Pneumonia of the right lung, tubercles in the Bronchial Glands.—Augustine Marain, ætat 19 months; vaccinated; never had convulsions; for the last four months has been affected with ophthalmia and eruptions on the face, followed two months after with crusta lactea, and with intense cough for the last five days. On her entry, the 28th February, she presented the following symptoms; slight dyspnœa; pneumonic furrow not very visible; cough not frequent; bronchial respiration in the whole of the right lung; on the left side sub-crepitant rhonchus; all the surface of the body is covered with a pale eruption somewhat similar to rubeola—large blister on the back; four leeches to the knees immediately, four more in the evening — 1st March, amelioration, bronchial respiration not so intense, and replaced in some places by a marked expiratory murmur, or by a sub-crepitant rhonchus; on the left side this last was heard only during the deep inspirations; pulse 120; the roseate spots are replaced by bluish ones; pneumonic furrow more visible—two leeches —℞. Looch. ℥iv. oxyd. antim. alb. gr. x., mistura; tertia pars quarta quaque hora sumend.—2nd—death took place at half past five. a.m. Autopsy, 28 hours after—*Thorax.*—Right lung. Inferior lobe, hepatized, of a very dark colour, of an aspect less granular than in the adult; the tint of the cut surface, uniform; superior lobe inferiorly and posteriorly presented the same lesions; the cut surface is not of so uniform a colour as the former, indicating evidently that they did not both commence at the same time; the diseased portions were distinctly separated from the sound; middle lobe in a similar state; no tubercles. Left Lung. Indurated nuclei are to be felt in the parenchyma, and seen on the surface; the superficial are of a darker colour than the surrounding parts; the tissue composing these indurations is hard, of a dark violet color, granular, and friable, as the parenchyma of the lungs in the 2nd degree of pneumonia in adults; no tubercles. No mucosities in the bronchi. Bronchial glands tumefied and almost all tubercular.

Œdema glottidis: Tracheotomy.—A. mason, ætat 19, affected with balano-posthitis ulcerosa; entered Dr. Packe's ward, Hospital *du Midi*;—this affection being sometimes of a syphilitic nature, inoculation was performed but without any result; when nearly well the patient was seized with cynanche tonsillaris, followed four days after by dysphagia, dyspnœa, and finally orthopnœa; the usual remedies having failed, and the face being violet, the extremities cold, the pulse very frequent and small, and the pupils very dilated, Dr. Ricord, convinced that death by suffocation would soon take place, decided upon performing tracheotomy. The crico-thyroidean membrane and the cricoid cartilage were promptly divided, and the edges of the wound kept open by small hooks, fixed to bits of tape, which were tied over the nape of the neck. Respiration took place through the artificial opening, and an hour after, the patient went to sleep. The pulse being full and large three hours after, six leeches were applied on each side of the neck. On the third day, the hooks were removed, and a canula introduced instead, and this last itself was taken out on the seventh day. Finally the wound was nearly closed fourteen days after the operation. The only consecutive symptoms were fever, insomnia, slight sibilant rhonchus, cough. This observation comes in support of the opinion of Dr. Vallin (Bull, de Ther. Jan. 1845) who considers this affection to be consecutive to one of the larynx (*Gaz. des Hopitaux.*)

Dr. Flandin, already well known by several remarkable memoirs—performed conjointly with Dr. Danger—on some of the most controverted toxicological questions, has just received the just and merited reward of his labours, being nominated member of the *Conseil de Salubrité*, vacant by the death of Dr. Olivier d' Angers. Fourteen candidates presented themselves, among whom the *Conseil* chose three, Drs. Flandin, Bricheteau, and Laugier; the nomination depending on the *prefect de police* and the minister of the Interior. The merit of the two unsuccessful candidates is sufficient, were this at all requisite, to show how highly the researches of the individual appointed have been appreciated.

Academy of Sciences, Sitting of the 14th April. —M. Elie de Beaumont in the chair. Received. On the morphology or the re-production of the sertilarian zoophyte, and its analogy with the reproductive system of the flowering plant, by E. Forbes, F.L.S., Professor of Botany at King's College, London. The electrical Magazine, conducted by Mr. Charles Walker, Vol. 1, No. 8. April, 1845. Journal of the Royal Agricultural Society of England, Vol. 5, 1845. Part 2nd.

M. Arago, whose lectures on astronomy at the Observatory here are so very popular, informed the Academy and the public that he was in no way cognizant of the work published under the title of "*Lecons d' Astronomie professes par M. Arago, recuillies par un de ses eleves,**" and that it is a very bad compilation, and full of the grossest errors, though, if the title page say true, it has reached its fourth edition.

On the Muscular Current.—M. Matteucci in a letter addressed from Pisa, to M. de Humboldt, states that he has obtained signs of electro-chemical decomposition by the muscular current, and from his researches concludes—that the intensity of the muscular current is in proportion to the activity of the aspiration—that the same result is obtained on frogs deprived of air, that is to say, in a state bordering on asphyxia, as when they are acted upon from 25° F. to 61° F.—that the result is the same, when instead of atmospheric air, other gases are employed (oxygen, carbonic acid)—that when hydrogen is made use of, the deviation remains constant for several hours—that it is in the muscle, in its organization, and by the chemical action which takes place in its interior on the living animal, or one recently killed, that the current exists—that there is a current peculiar not only to the muscles of the frog, but likewise to all the muscles of animals, provided their extremities are tendinous; that all these muscles possess a current directed from the tendinous extremity to the surface. The same author gives the details of some experiments on the electrical discharge of the Leyden jar.

On a powder known by the name of Bleu d' Azur. by M. C. Briffaud.—The different varieties of *Bleu d' azur*, (composed of oxyde of cobalt, siliceous sand, oxyde of iron, and potass) are known in trade under the denomination of *azur* 1st degree, *azur* 2nd degree, &c. according to the colour and the impalpability of the powder. From analyses performed on several varieties, (8th, 6th, 2nd, 1st, degrees and pale *azur*) the author concludes—that this powder contains a considerable proportion of arsenic, which may easily be separated by water—that the presence of a soluble arsenical compound, in the powders obtained by calcination is highly interesting, and that this powder ought not to be employed by confectioners to colour their sweetmeats, nor in the different domestic usages.

On Azotized Componnds. By M. Aug. Laurent.—This author, in this memoir, continues his researches and gives the following formulas. *Quinine*—formula, $C^{38} H^{22} Az^{2} O^{2}$; may be converted by means of potass into *chinoline*, thus $C^{38} A^{22} Az^{2} O^{2} = C^{31} H^{14} Az^{2} + C^{2} O^{2} + H^{8}$ —*Cinchonine*—formula, $C^{38} H^{22} Az^{2} O$ — *bichlohydrate of cinchonine*, may be obtained in beautiful crystals by evaporating its solution *in vacuo*: formula, $C^{76} H^{44} Az^{4} O^{2} + H^{4} Cl^{4}$ — *bichloroplatinate of cinchonine*, formula $C^{76} H^{44} Az^{4} O^{2} + 2 (H^{2} Cl^{2} + Cl^{4} Pt.) + 2 H O$; by the addition of an atom of water, cinchonine is changed into *chinoline*, thus $C^{38} H^{22} Az^{2} O + H^{2} O = C^{36} H^{14} Az^{2} + C^{2} O + H^{10}$.—*Morphine*, formula $C^{68} H^{38} Az^{2} O^{6}$; *hydrochlorate of morphine* $C^{68} H^{38} Az^{2} O^{6} + H^{2} Cl^{2}$.—*Piperin*, formula as indicated by M. Regnault.—*Lophine*, $C^{92} H^{32} Az^{4}$.—*Picryle*, $C^{84} H^{30} Az^{2} O^{4}$; *chloro-picryle*, $C^{84} H^{30} Az^{2} O^{4} Cl^{2}$; *bromo-picryle*, $C^{84} H^{30} Az^{2} O^{4} Br^{2}$. *Coneine*, $C^{32} H^{30} Az^{2}$.—*Narcotine*, $C^{92} H^{50} Az^{2} O^{14}$ is changed by oxydation into *cotarnine*, $C^{52} H^{26} Az^{2} O^{6}$; the residuum $C^{40} H^{24} O^{8}$ when oxydyzed gives *opianic acid* $C^{40} H^{20} O^{10}$, a monobasic compound, which, when oxydised anew, furnishes a bibasic (hemipinic acid) $C^{40} H^{20} O^{12}$. *Narcogenine* is the result of the action of narcotine and cotarnine on each other; formula, $C^{144} H^{70} Az^{4} O^{20}$. Several other compounds have been studied, but the formulas are not given.

On the Functions of the Pancreas and its Influence on Digestion. By MM. Bourchardat and Sandras. —From the facts contained in this memoir the authors conclude:—That the pancreas is the organ which, in animals living on feculent substances, secretes the principle (*diastase*) specially destined to dissolve the food, so as to enable it to be absorbed, and that diastase also exists in the bile, saliva, and the secretion of the gastric mucous membrane.

On the Equivalents of several Simple Bodies. By M. J. Pelouze, M.A.S., &c. The progress analytical chemistry has made of late renders it possible to attain a correctness unknown at the period Berzelius established the laws by which chemical compositions took place. Thus, in carbonic acid, Professor Dumas has proved that the atomic weight of carbon was not 76.44 but 75·00; the same *savant* discovered, that the equivalents of hydrogen and calcium were 12·5 and 250. It, therefore, appeared that the hypothesis of Prout on equivalents, considered as multiples of a single body, *hydrogen*, was not without foundation; and new substances—azoto, chlorine, sulphur, zinc, bromine, mercury, borium, strontium—were added. This hypothesis was generally admitted until the researches of M. Marignac proved that the equivalent of chloride of potassium was not a multiple of that of hydrogen, and that one, if not both, were exceptions to the general rule. In the following table, the author gives the results of his researches on the equivalents of various metals compared with those of Berzelius.

			Berzelius.
Sodium	287·17	..	290·90
Potassium	489·30	..	489·92
Barium	858·03	..	856·88
Strontium	548·65	..	547·29
Azote............	175·08	..	177·03
Silicium..........	88·915	..	92·43
Phosphorus	400·00	..	392·29
Arsenic	937·50	..	940·08

Shewing that the greatest difference is between the eq. of phosphorus. If these numbers were divided by 12·5, the eq. of hydrogen, some give a very different result from that law indicated

* This is neither improbable nor indeed astonishing, for the public, from the way in which the work is announced, have naturally concluded that it contained the ideas of the illustrious *savant*, (G. de B.)

by Prout, whilst others—phosphorus, azote, arsenic—coincide with it, their eq. being multiples of that of hydrogen. Finally, it is principally the elements of organic bodies whose eq. seem always multiples of that of hydrogen.

On the Sulpho-Arseniuret of Lead, by M. A. Damour, presented by M. Dufrenoy, M.A.S.—This substance is found on Mont St. Gothard in trapezoid crystals, but generally in amorphous masses; it is combined with realgar and copper; from its brightness it has often been confounded with the latter, but it may be distinguished by its being somewhat similar to resin, and by its powder, which is of a reddish brown; specific gravity, 5·519; heated with charcoal it melts rapidly, disengages gases which offer at first a sulphurous, and afterwards an arsenical smell, and leaves a small globule of lead, malleable, and surrounded with a yellow circle; heated in a closed tube, realgar is sublimated, and appears in the form of small transparent globules. Composition:—

	1st analysis.		2d analysis.

MM. Danger and Flandin addressed the following letter:—"The Academy at the sitting of last week received two letters—one from Professor Orfila, the other from M. Barse. It is with infinite regret that we find ourselves obliged to reply, the more so, as science derives no benefit from discussions which have no motive but personal interest. On the faith of a periodical, Professor Orfila reproaches us with having erroneously attacked the report presented by MM. Pelletier, Chevalier, and himself; now, had he waited until the publication of the memoir,* he would have perceived that the report was not mentioned, but only experiments, owing to which two chemists, led astray by Smithson's apparatus, thought that mercury existed in a liquid which contained none. The error, as we stated, was rectified, and the precept was then given not to be content with the change of colour of the gold, but to affirm that mercury was present, only when globules of that metal could be obtained by heating the apparatus in a tube." Had Professor Orfila read this phrase, he would not have reclaimed the priority of an idea of which we never thought of depriving him—that of volatilizing in a tube the mercury on the gold of Smithson's apparatus. By mentioning that he had published "a memoir in which he indicated the various errors to which this apparatus may give rise, and the means by which they may be avoided," Professor Orfila owns that the error of which we spoke really existed; now in no part of our memoir did we say aught from which it might be concluded, that it was the report presented by the experts. However as the celebrated toxicologist is not explicit as to the errors and plagiaries he imputes to us, we cannot do more than join in the wish he expresses, that the committee named by the Academy to present a report on our memoirs, should do so as speedily as possible. The author of the second letter is more explicit than the master whose doctrines he upholds, as he declares what he considers to be our plagiaries and our errors:—1°. That we announced as a novelty, in 1842, the concentration of poisons in the liver, a fact published by Professor Orfila in 1840. But, we would ask those who have attentively studied this subject—what is the exact date of the expression, *concentration of poisons in the liver?* Is it not posterior to that of *localization of poisons*, by which we first drew the attention of physiologists to this curious and unexpected phenomenon—that poisons were not equally distributed in the various parts of the body; that tartar emetic was never found in the lungs, nor copper in the urine, &c.? In order to explain why the liver contained a greater quantity of poison than the other organs, Professor Orfila referred to its vascularity, and the nature of its functions as a secreting organ. Now, we think we *first* indicated that poisons were carried directly to the liver, principally by the vena portæ, formerly empirically denominated the *porta malorum*. And were not these ideas novel, and deserving the attention of physiologists? 2°. That several propositions advanced by us are inexact—(*a*) "that without containing a particle of arsenic, some spots may offer the physical characters, and produce the same result with the different chemical tests of the real arsenical spots." The Academy has announced its opinion on this subject; every body is aware that this learned body has declared "Marsh's apparatus of no use as far as the spots were concerned."* Nothing, therefore, need be added. (*b*) "That the earth of cemeteries contained no arsenic." How is it possible that we could have made such an assertion? Arsenic is one of the minerals which constitute the elements of our globe; therefore, may it not, must it not happen that cemeteries have been formed in parts that naturally contain arsenic? From several experiments on some earth taken from three of the principal cemeteries round Paris, we certainly stated that we did not find any arsenic. But in reading what we published on this subject, it will be seen that we did not even insinuate that the absence of arsenic on one spot necessarily precluded its existence elsewhere. One ought to grant one's adversaries at least common sense. (*c*) "That animals when poisoned do not urinate." In *acute* poisoning with arsenic, we stated that in general animals do not urinate. The absence, or minute quantity of urine is a symptom of this species of poisoning, a fact with which practitioners are acquainted; and we have, in the numerous judiciary reports drawn up by distinguished experimentalists, found the conclusions to which we were led by our first experiments on animals, confirmed by the facts observed on man. (*d*) "That copper does not exist in our organs in their normal state." We maintain our opinion, but at the same time would request that the terms *normal copper* and *accidental copper* be not confounded. (*e*) "That no poison is to be found in the blood of animals when poisoned." The proposition emitted was far from being so absolute. We said that *certain poisons* (copper and lead) would not be met with in the blood. But we know that arsenic and antimony may be found, and we trust from this fact to be able to draw some conclusions useful in a therapeutic point of view. (*f*) Finally he protests against the assertion "that, in judiciary experiments, the animal matter had better be divided, and that for instance, it is sufficient to examine three or four ounces of liver to prove the presence of the poison." This division, in these enquiries is in our opinion, useful, and even in every case it ought to be done. Recent experiments have proved the correctness of this opinion, and we therefore, maintain it; let it however be clearly understood, that we do not limit the researches to so small a portion if no poison is discovered; in these cases, we must analyse half a pound, a pound and even two pounds. To conclude, as doubtless the Academy is wearied with these long and useless discussions, in future we will reply to no reclamations no better founded than those just answered."

M. Carillon writes, stating that he has invented a machine (of which a drawing is given) by which lustre may be given to the paper in stained paper manufactories without incommoding the workmen.

Academy of Medicine. Sitting of the 15th April. M. Caventou in the chair.—Received statistical tables of mortality in London.

On the Plague.—M. Hamont, corresponding member, addressed a letter on this subject, in reply to one from Dr. Aubert Roche, which terminates with the following *resumé*:—Cases of plague were observed on the guardians of lazarettos, after the arrival of infected vessels. Ought men and merchandize to be permitted to be put on shore, without paying attention to sanatory measures? I do not think this ought to be permitted in every case; but goods must be exposed to the air for several days, so as to do away with the infectious principle. Dr. Aubert-Roche requests that the quarantine be limited to twelve or thirteen days, voyage included, when no sickness is on board; I would wish it to be fifteen, as in England. Quarantines are not suppressed in England, but all vessels which have been *at least* fifteen days at sea, are permitted to land passengers and goods: but if cases of plague had been observed during the passage, a quarantine, longer or shorter, according as the cases may be, is rendered obligatory. Finally, M. Hamont coincides with Dr. Aubert-Roche in the opinion that it is necessary to reform the sanatory laws in France.

On the Extent of Surface of the Brain, and its relations to development of Intelligence.—This interesting memoir, read by Dr. Baillarger, one of the candidates for the vacant place in the section of anatomy and physiology, and distinguished for his researches on mental diseases, will shortly be published in the *Medical Times*.

Professor Roux read a long memoir on Exostosis.

Fragment of a Sound in the Bladder.—Dr. Leroy d'Etiolles shewed the Academy the fragment of a gum elastic sound of a large calibre, 2¾ inches in length, which he extracted *per urethram* from the bladder of an old priest living at the Batignolles near Paris. It had been in the bladder for more than three months, and its surface was already covered with a calculous incrustation, which was detached and previously removed. The instrument made use of is so disposed that if the sound is seized transversely, it is bent, the two extremities turned backwards, so that when cut in two, one remains between its branches, and being in the direction of the urethra may easily be extracted. When the sound is very small it may be extracted, bent in two, without being divided. Dr. Leroy d'Etiolles mentions the case of a young woman, from whose bladder he extracted the handle of a mustard spoon in box-wood, 3½ inches in length, without producing the slightest accident.

GARLAND DE BEAUMONT, D.M.P.L., & S., &c.
Honorary Physician to the Spanish Embassy.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M. D.

On the Endermic use of Strychnia in Functional Amaurosis.—Pure strychnia, when used by the endermic method, exerts an effect equal to that of the nitrate, or hydrochlorate. If rubbed into the vicinity of the eye in quantity so small as that of a quarter of a grain, it produces a sensation of violent burning, with increased lacrymal secretion, accelerated pulse, head-ache, vertigo, and obstructed respiration. Two or three hours after it has been applied, convulsive movements set in, accompanied with shooting pains in the head, extending to the affected eye; these disappear as soon as diaphoresis is induced. Two grains and a half produce the above symptoms, besides great restlessness. The author prefers the endermic, to the internal use of strychnia: 1. Because the remedy can be applied to the affected spot itself. 2. Because smaller doses are required. 3. Because a useful change of remedies can be more easily effected. For the purpose of excoriation, a blister is used by the author in preference to other means. He applies it to the supra-orbital, or temporal region, and when the part is excoriated, the strychnia, mixed with saliva, is then rubbed in; and the wounded spot covered with waxed paper. It is necessary to begin with the smallest dose of strychnia, and to increase it gradually and carefully. The writer of this paper strongly dissuades medical men from directing the application of strychnia behind the ears, as he has witnessed violent tetanic convulsions from such an application.—*Dr. Wimmer, of Munich, in Neu Medic. Chirurg. Zeitung.*

On the use of a Mild Preparation of Scammony.—A purgative nostrum, used by the late Dr. Baader, which has been made public since his death, turns out to be nothing more than a resinous extract of scammony. His method of preparing it was as follows: A quantity of powdered Aleppo scammony

---

* *Vide* the memoir published in the "*Medical Times.*"

* *Vide* Comptes Rendus de l'Acad. des Sciences, vol. xiii. p. 57

was put into a digesting glass, and as much rectified spirit poured over it as would rise about an inch over the powder. The mixture was then exposed to a moderate temperature, and shaken several times a day. After a week, the liquid was filtered, and the yellow solution decanted off. Pure water was poured into the resinous solution as long as a precipitate appeared. The liquid used to precipitate the resin, was next distilled to save the spirit, and a small quantity of dirty resin poured in the distilling apparatus. The pure resin is agitated with pure water until all its peculiar taste is lost; it is afterwards dried at a gentle heat. In this state it is transparent and brittle as glass. Baader disguised this preparation by mixing with it gum. Arab., and balsam of Canada, Castile soap, and almond syrup. Latterly, he administered it mixed with powdered biscuit, in which form children take it most easily.

The following is Baader's formula for the administration of his preparation:—℞. Resinæ Scammonii, ʒiij.; Saponis Veneti, gr. v.; Sacchari duri gr. lv.; Misceantur intime terendo. Denique pulveri additur. Panis vulgo dicti, *Biscuit*, ℥j.; Conterentur simul, denuo servetur pulvis in phialâ obtuturatâ.

Each drachm of this powder contains six grains of resin of scammony. Its doses may be graduated thus: Children, 2 years old, 5 grains; ditto, 8 years old, 10 to 15 grains; adults, 1 drachm to 2 drachms.—(*Dr. Wimmer of Munich, Opere Citato.*)

Chronic Enteritis and Gastritis probably caused by the excessive use of Morison's Pills.—A gentleman 47 years of age, had used Morison's pills against hereditary tetter, (herpes) with some apparent advantage, and became by that means so prejudiced in their favour, that he took them on every occasion, and made his family also use them. (He consumed in a year and a half, pills to the value of £25.) When in his 24th year, he suffered from obstinate intermittent fever, and latterly with a gastro-nervous fever, which underwent a relapse, and produced a most depressing effect on his mind, terminating in monomania, so that he believed that mortification of the viscera had taken place. Hydropathic treatment, change of air, all were employed in vain, and he was at last placed in the author's private lunatic establishment. He complained of lancinating and cutting pains in the abdomen, under the short ribs, increasing periodically in violence; for several months he had not been able to lie on his back. On the third of September, he was evidently in great pain in the abdomen, and labored under intense thirst. These symptoms continued to increase till the 5th, when he died, notwithstanding the employment of energetic antiphlogistic treatment. The *post-mortem* examination showed a spot in the duodenum, affected with recent gangrenous inflammation; and in a considerable portion of the small intestines, the mucous folds were very prominent, much injected and of a fleshy consistence. A great number of spots were perceived, probably the openings of degenerated mucous glands; in the ascending colon, and a little further in, there was found a spot which was almost black. The small intestines contained a reddish pus-like liquid; there were cicatrices on the mucous membrane of the fundus of the stomach, one of which was decidedly the result of a perforating ulcer. The membrane was also thickened and injected in several places. The author ascribes the inflammation and subsequent insanity, to the excessive use of drastic pills. They must have caused great irritation in the already weakened bowels, and caused a metastasis of the skin-disease to the abdomen, as frequently happens. Disorder of the small intestines may affect the understanding (intellect) whilst disease of the large intestines rather tends to affect the feelings. Constipation and the consequent pressure on the abdominal organs and diaphragm, most certainly influence mental derangement. The greater the evidences of the failure of the voluntary power in the maniac, the more certainly will the cause of the aberration be found in the abdomen.—*Dr. Whittfeld and Dr. Albers, in Rhein. id. Westphal. medic. correspond. bl.*

Osseous Concretions in the Epiploon and Spleen.—In the body of a woman who died at the age of 65, from abdominal disease, an osseous concretion of the size of a walnut, was found in the right side of the epiploon, surrounded with a layer of fat, and of the shape of a walnut. It weighed one drachm, and had a smooth surface. A larger osseous concretion, weighing half an ounce, and measuring 3 inches in length, 1½ inches in breadth, and 4 inches in thickness, was found at the convex part of the spleen; its external surface was likewise smooth, the internal rough and unequal; both consisted of phosphate and carbonate of lime. The liver was enlarged.—(*Dr. Rock in Allgemein. Zeit. fur Chirurgie.*)

Syphilis Congenita.—F. ætat. 40, had a chancre 12 years ago, and was treated by a quack with pills, which probably consisted of sublimate. He rapidly increased the dose from 2 to 80; the larger doses invariably caused violent pain of the stomach, lasting for hours. A cure was effected in four weeks. During the treatment, the patient drank freely of brandy. Three years after this he married. His wife bore a healthy child, still living. The next five children were born apparently healthy, but were all seized five or six weeks after birth, with an eruption of the skin, during which they emaciated and died in a few weeks. When the next child was similarly attacked, the author was called in, and he found gradually enlarging pustules on the scrotum, anus, and internal side of the thighs. Eight days after, the penis and legs were covered with superficial ulcers; the skin between the ulcers was of a copper red colour; the child was greatly emaciated, and cried almost constantly in a hoarse, crowing tone. The author exhibited ¼ of a grain of hydrarg. oxydul. nigr. with carbonate of magnesia three times a day, and cured the child in a fortnight. The child was constantly suckled by the mother during the treatment, but the nipples were washed after each suckling. The child, as well as the parents, now enjoy perfect health.—*Dr. Maenicke in Rhein. id Westphal. Correspondenz blatt.*

Birth of Four Children.—A healthy, strong woman, ætat. 35, after having had five children, became pregnant again, and this time her abdomen appeared to be of larger dimensions than usual. During the subsequent process of parturition, the waters were discharged sparingly; one child presented itself with the feet, and was expelled by the efforts of nature. Half an hour after, the birth of the second child began and was terminated in an hour. The third and fourth children (apparently still-born) speedily followed. The quantity of water discharged was about 2lb. After one hour and three quarters, four separate placentæ were expelled. These four children (boys) were all born with the feet foremost; they were all perfectly mature and well formed; they resembled each other, and performed their functions regularly. Their length averaged from 15¼ to 17 inches, their weight from 3lb. to 4lb. They all died within the next five days, notwithstanding the greatest care was taken of them as regards their nourishment and preservation. The mother left her bed five days after delivery, and remains in very good health.—(*Prof. Pfau in Oester. Medic. Wochenschr.*)

The History of a Human Anencephalus.—The following case confirms the existence of a system of excito-motory functions dependent on the spinal marrow, independently of the brain. A loaded cannon took off the head of the soldier who fired it; nothing was left of the whole face but the tongue and the lower jaw. The tongue was in violent convulsive motion, and the respiration deep, slow, and rattling. Both continued in this state for seven minutes and a half, when they became gradually slower and more rare, and ultimately ceased 15 minutes from the time of the accident. The whole brain (cerebrum and cerebellum) lay torn and scattered about; a few small pieces of the ossa parietalia were still hanging to torn pieces of the skin; the os basilare, with the foramen occipitale was still present, and showed the torn portion of the medulla oblongata. —(*Dr. Schleifer in Oesterr. Medic. Wochenschr.*)

On the Convulsions of New-born Children.—The author only treats of the epileptic convulsions (epilepsia eclampsia neonatorum. Meissner.) and not of involuntary movements of the muscles of the face, eyes, or extremities. Meissner believes these convulsions to be rarely idiopathic, but most generally symptomatic, or reflex of diseases of the reproductive system. The observations collected in the Lying-in and Foundling Hospitals of Prague, led the author to the following results. Out of 2,500 infants only nine cases of well marked convulsions appeared, all of them caused by a derangement of the central nervous system. The disease might be regarded in almost all these cases as primary; but in two cases suppurative phlebitis umbilicalis seemed to be connected with the cause. In the other cases, hemorrhage was found to have occurred within the skull, or the cavity of the spinal marrow, on the *dura mater*, rarely between the membranes, and never in the substance of the brain. As regards the *causes* of the hemorrhage, nothing could be ascertained; neither difficult nor artificial labour, neither artificial nor natural birth, seemed to exert any influence. In all convulsions produced by affection of the brain, the temperature of the head was increased, the facial muscles distorted (as also in hydrencephalus), and in two cases there was an erection of the penis; in convulsions, however, proceeding from affection of the spinal marrow, opisthotonos appeared, with contractions of the extremities; and increased temperature of the head was a later symptom, so that the seat of the hemorrhage may be presumed from these symptoms. The pulse could not be counted in any instance; the urine and fæces were rarely evacuated. The first attack never appeared before the second day after the birth, and one case only, on the 12th day, when the dissection distinctly showed that the extravasation of blood must have taken place several days before. [This shows that it is not every extravasation of blood that produces convulsions, but that it only favours convulsive tendency.] The paroxysms were repeated in some cases every three minutes, in others every hour. In the intervals, the children appeared in a state of stupor. The author did not see any child recover from real convulsions. The course of the disease was always very acute, varying from an hour to one or two days, when it invariably terminated fatally. A powerful antiphlogistic treatment seemed alone to have any beneficial influence.—*Dr. Schleifer of Neuhofen in Oesterr. Medic. Wochenschr.*

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN SCIENCE.

(The following are the principal articles of interest to our readers in a recent number of the *Lancet*.)

Dislocation of the Shoulder.—Mr. Potter had an opportunity, in the dissecting-room belonging to University College, of dissecting a shoulder in which dislocation of the humerus had taken place. The following were the appearances presented:—the capsular ligament was extensively ruptured on the outer aspect of the joint, between the tendons of the sub-scapularis and supra-spinatus muscles. The opening, large enough to allow the head of the humerus to pass readily through it, communicated with a large bursa, which lined the under surface of the acromion, forming a species of false joint between that process of bone, and the upper and outer part of the head of the humerus. The long tendon of the biceps was torn through, near its origin, from the margin of the glenoid cavity; it appeared to have retracted, and was closely united to the bicipital groove by means of slender semi-transparent shreds, attached somewhat after the manner in which the columnæ carneæ are attached to the walls of the heart. The tendons of the supra-spinatus and infra-spinatus muscles were stripped completely from their natural insertion into the upper part of the great tuberosity of the humerus, but retained their connexion with the teres minor, through the medium of which they were indirectly attached to the neck of the bone. The supra-spinatus muscle was pale and atrophied, and forced to pass in a curved direction round the head of the humerus, leaving its upper part bare and rough. No ulceration appeared on the surface of the cartilage, though its margins were fringed with numerous little fleshy projections, as if

lymph had been deposited there, and organized during the process of repairing the injury in the capsular ligament. From these appearances, Mr. Potter concludes that the primary injury had been a dislocation of the head of the humerus forwards and upwards.

RETENTION OF URINE, CAUSED BY OBSTRUCTION IN THE RECTUM.—Mr. Todd narrates the case of a man, 62 years of age, who, after partaking several times of pease pudding, made with whole grey peas, was seized with retention of urine, and symptoms indicative of obstruction in the rectum. The retention was relieved on several occasions by the use of the catheter, and the obstruction was finally overcome by purgative enemata. The patient recovered.

ULCERATION OF THE IRIS.—A case of syphilitic iritis is reported from the London Hospital, in which there was great deposit of lymph, and the formation of an abscess in the texture of the iris. A mercurial treatment, combined with tonics was prescribed, and under its influence the effusion of lymph was gradually absorbed. When this had been removed sufficiently to allow the iris to be seen, its structure appeared as if it was considerably attenuated at the spot in which the lymph had been most abundantly deposited: and in a few days, when a more complete view was obtained, it was evident that there was an absolute deficiency in the iris, that ulceration had taken place, and a fissure, extending from its pupillary margin to one half its depth, was left; the margins of this fissure were firmly bound to the capsule of the lens, so that belladonna had no effect in altering its dimensions: and, indeed, there was but little action in any portion of the iris, and that only in the superior part, the remainder being irregularly adherent. When the patient left the hospital, the fissure was somewhat diminished in size; the edges having become slightly approximated.

EXTRAORDINARY EFFECTS OF LIGHTNING.—Dr. Le Conte, of Savannah, in the *New York Journal of Medicine* states that five negresses were simultaneously prostrated by a single stroke of lightning on a plantation in Georgia. The sun was shining brilliantly at the time, and a greater portion of the visible hemisphere presented the usual serenity of the summer sky. A singular and rather angry-looking cloud had, for a short time previously, been observed near the verge of the south-eastern horizon, from which occasionally proceeded the low rumblings of very distant thunder. Suddenly the whole atmosphere was illumined by a flash, succeeded by a single report, and the cloud quickly dispersed precipitating a little rain. The five negresses were all taken up in a state of apparent death. The 1st case, that of a negress, aged about thirteen years, who was up in the branches of a small mulberry-tree, twenty feet high, and standing sixteen feet in front of a line of negro houses, which extended parallel to a wood situated one hundred yards in the rear of the same. She was engaged in throwing down the fruit for her little companion below. Every principle of life seems to have been instantly extinguished by the intensity of the electrical shock*:—her body had to be taken down from the branches of the tree where it had lodged. No marks of external injury observed. The 2nd, was that of a female child, aged about six years, who was standing immediately under the tree. She was instantaneously killed. No superficial marks of injury observed. The 3rd, was that of an adult woman, aged forty years, who was walking about ten feet more remote from the base of the tree than the latter child; and, also, about five feet more distant than the two who survived the shock, viz.: than cases 4 and 5. She was instantly killed. No marks of injury recognized, excepting a burnt spot, the size of a dollar, under the right axilla. Her clothes were set on fire: but this was probably occasioned by the breaking of a tobacco pipe which she was smoking at the time, and which scattered its ignited contents over her cotton garments. In the three cases above-mentioned, all the ordinary attainable means of resuscitation were tried without success. 4th, also that of an adult woman, aged twenty-nine years, who was standing half-way between cases 2 and 3, and, consequently, about five feet from the root of the tree. After remaining in a state of insensibility for some time, she gradually recovered her consciousness. A dose of castor-oil was then administered. The skin on her right shoulder was abraded for a space as large as a dollar. Her clothes were rent into shreds; on the right side of her body, the skin was blistered, and marked with discoloured streaks, which extended anteriorly on the lower portion of the abdomen towards the pubes. A small streak likewise extended along the interior aspect of the right arm. She complained of pain in the stomach and bowels for three weeks. No vomiting nor burning in the hands and feet, as was experienced in the next case. She has been married several years, but has never been pregnant. Her menstruation was perfectly regular prior to the reception of the shock; but has since that time been very irregular; sometimes having two periods per month, and then escaping two months. The flow has also been much diminished in quantity. Her health has not been very good since she was struck; manifestly resulting from her menstrual irregularity. A recent copious bleeding has afforded her evident and immediate relief. Her reproductive functions appear to continue dormant. The 5th, was that of an aged woman, at least seventy years, who was standing immediately beside the last. She, likewise, gradually recovered her consciousness. No medicine was administered. Her clothes were rent; and after a few days, marks of discolouration were manifested along the right arm and right side of the trunk. A violent paroxysm of vomiting followed the restoration to a state of sensibility; which continued, with occasional interruptions, for ten or twelve hours. As in the preceding case, she complained very much of pain in the region of the stomach and bowels, for at least two weeks after the accident. A troublesome sensation of burning was experienced in the palms of her hands and the soles of her feet; and in the course of two or three weeks a swelling made its appearance under the right foot, which ultimately resulted in the exfoliation of a portion of the thick, indurated epidermis of that part, about one and a half inches in diameter. The catamenial discharge, which had, in accordance with the ordinary arrangement of nature, ceased for more than twenty years, was completely and, thus far, permanently re-established. At least, a discharge from the genital organs, having all the obvious and sensible physical characters of the catamenia, and observing, with rigorous exactitude, its peculiar law of periodicity, has been established, and continues to recur, with the utmost regularity, up to the present time, (Aug., 1844), after the lapse of more than a year. She has not missed a single menstrual period since she was struck by lightning. To use a liberal paraphrase of her own language, her 'moons return as regularly as when she was a young woman.' The flow comes on with the usual premonitory symptoms. Her mammæ have undergone an obvious preternatural enlargement, apparently originating in a sympathetic irritation, emanating from the establishment of the reproductive functions. This woman has but one child, to which she gave birth, soon after reaching womanhood. The catamenial flux is represented to have been regular up to the period of its natural cessation, between forty-five and fifty years of age; subsequently to which epoch, she has presented all the appearances ordinarily attending the gradual approach of the state of senility in a vigorous constitution. The electrical shock, likewise, completely relieved her of a troublesome strangury which had harassed her for four or five years. Very recently she has occasionally had a slight recurrence of the same complaint, although in a much milder form. Otherwise, her health continues perfectly good; there being, so far as symptoms show, not the slightest indication of the supervention of organic disease of the uterus.

REMOVAL OF A DISEASED OVARIUM.—Dr. J. D. Bowles, of Harrison, Ohio, in the *Western Lancet*, states that Mrs. Brant, aged 25, in the middle of August, 1843, for the first time noticed a small tumour in the left hypogastric region, which had unceasingly continued to increase; it now occupies the whole lower part of the abdomen, and extends upwards to midway between the umbilicus and ensiform cartilage; it is very movable in a lateral and somewhat in a vertical direction; its surface feels hard and uneven as if lobulated. Upon examination the vagina and os uteri feel healthy; the direction of the vagina inclines to the left; pressure to the right of the neck of the uterus gives slight pain; here, through the vagina, the tumour can be felt. She complains of pains in the lumbar region, and down the thighs, at times resembling those of parturition. The urine is frequently and rather painfully voided. The bowels are inclined to be costive: in other respects, the various functions of the body are performed in a healthy manner. In pursuance with the opinion expressed at a consultation, Dr. Bowles proceeded to operate upon the plan pursued by McDowell, Lizars, and Clay. The patient having her bladder and rectum evacuated, was laid on a table; her head resting on a pillow; her legs hanging over the end, and her feet resting on a chair. Avoiding the umbilicus, an incision nine inches in length was made through the linea alba, from the upper part of the tumour to the symphysis pubis. Upon drawing aside the parietes, the tumour might be seen through the greater omentum, which passed down in front of it: upon endeavouring to raise it, it was found adherent to the tumour. The adhesions were readily separated by the handle of the scalpel or fingers. There were no adhesions on the posterior part. In endeavouring to raise it from the right iliac fossa, its attachment to the broad ligament of the uterus, which formed the pedicle, was brought into view; the pedicle was about two inches wide; its broad surface closely adhered to the tumour; its blood-vessels were large and distended; following its course for a short distance, the finger could be passed around it; here a ligature of double silk was applied, and firmly tied, and passed through the pedicle between the tumour and place of application; the broad ligament was then cut through. Endeavouring to raise it from the right iliac fossa, it was found firmly bound down by adhesions to the uterus and bladder; the close adhesion of the tumour to the former gave to the hand, when examining it from behind, a sensation as if their structures were intimately blended into one consolidated mass, but as soon as the pedicle was divided, upon raising the tumour in front, the adhesions between it and the fundus of the bladder and uterus, were easily separated by the handle of the scalpel, and the tumour was removed. She was placed on one side, that the accumulated blood might escape, of which not more than six or eight ounces were lost, and not a jet of arterial blood was seen. Upon being replaced in her former position, vomiting occurred, which forcibly protruded the intestines from the wound, and rendered it somewhat difficult to replace them, but Dr. Fuller by well directed pressure resisted the propulsive action, and stimuli being administered, the vomiting subsided. The wound was then closed by an interrupted suture of five stitches. At distances of an inch and a half, long strips of adhesive plaster, reaching across the abdomen, were applied between the sutures; a long compress on each side of the wound; raw cotton over it; and a broad bandage surrounding the body, enveloped the whole. Since the operation she has gone on well, and has had nothing to complain of, excepting that on the remainder of the fifth, and until the evening of the following day, her stomach would retain nothing; it yielded to an effervescent, or gruel. From that period she cannot be said to have an untoward symptom. Her diet was the mildest that could be suggested; and a dose or two of morphine the only medicine administered. To keep her abdominal muscles at rest, her urine was constantly drawn drawn off by the catheter, and her bowels washed out by enemata; to prevent distension from flatulence a tube was kept in the rectum. Three of the sutures were removed on the 9th, one on the 10th, and the remaining one on the 11th. Adhesion has taken place (with the exception of an inch near the lower part) throughout the wound; the ligature is not yet come away. The urine and fæces are discharged without difficulty or assistance. Her appetite is good; her health better

than before the operation. There is no doubt of her ultimate recovery. The tumour weighed five lbs.; its external appearance resembled the human brain enveloped in the pia mater: upon dividing it, the interior seemed quite solid, resembling the mammary gland, having a dense white appearance, agreeing with Dr. Good's definition of the emphyma mammarium. It measures in its shortest circumference fifteen inches, in its longest twenty-two and a half. The adhesions and solidity of the tumour would have rendered its extraction totally impossible by the short incision. The propriety of operating in the linea alba was manifested by finding the pedicle to be the right broad ligament, instead of the left, as we expected from the history given by the patient.

Rupture of the Spleen.—A robust man, about 40 years old, was engaged in a scuffle with another of the same size, and received a blow from the fist of his opponent, in the left hypochondriac region; the combatants then clenched each other, and so equal were their exertions for five or ten minutes, that it seemed doubtful which would come off victor; at length, however, the strength of J. W. seemed suddenly to fail. He turned pale, staggered and sank helpless upon the ground, complaining of nausea, faintness, and pain in the left side. He was carried, in a sinking condition, a short distance to a house, where he expired, in about fifteen minutes after the termination of the conflict. On dissection, twenty-four hours after death, no marks of violence were observed on the exterior. The cavity of the pericardium contained about two ounces of effused serum. In other respects, the contents of the thorax appeared natural. But upon cutting through the abdominal parietes, exit was given to between two and three quarts of dark, partially coagulated blood. An extended incision brought into view the spleen, enlarged to about five times its natural dimensions, and so soft in texture as to be easily broken down; under slight pressure with the finger. Upon its posterior surface, was a lacerated fissure of about five inches in length, extending deep into the centre of the organ. It was evidently from the divided blood-vessels of this torn structure, that internal hemorrhage had taken place to such an extent as to cause immediate death. The coroner's verdict was as follows:—"Death from lacerated diseased spleen, caused by a blow, fall, or over-exertion, while engaged in a scuffle with B. R.". B. R. was tried for manslaughter, and acquitted, by the Circuit Court.—*Dr. Herrick, in Illinois Medical Journal.*

Fracture during Pregnancy.—Dr. H. C. Marthens relates, in the *St. Louis Medical and Surgical Journal*, a case of fracture of the radius in a woman 30 years of age, at the time in the seventh month of pregnancy. The fracture united firmly in one month,—as short a period as union would have occurred under ordinary circumstances.

Foreign body in the rectum.—Mr. Blanchard, of Pimlico, in a communication which he has obligingly forwarded us, states that he was called to a man who he found in a state of great prostration, and apparently dying; on recovering from which the man complained of agonizing pain about the anus, with which he was seized while at the water-closet, where he fainted. Mr. Blanchard examined him, and saw a piece of black thread about an inch long hanging from the bowel. On introducing the finger, he found a needle with its point downwards about three inches up the rectum sticking in the gut. He experienced considerable difficulty in extracting it, in consequence of its position, &c., but after repeated and careful attempts, succeeded, and found it to be a tailor's needle with about half a foot of black thread attached. Inflammation commenced in the neighbouring parts on the second day, but by the application of leeches and other antiphlogistic means, the man got well in a week.

Memoranda on natural labour.—Mr. Close, of Manchester, promises, in a recently received communication, to draw up for the convenience of the student of midwifery, a synopsis or chart of most of those points which are of bed-side importance, and which ought to be indelibly fixed on his recollection. The following are the memoranda which he supplies with reference to the theory and practice of natural labour. The student should closely study and remember: 1.—The construction of the pelvis—the promontory of the sacrum—the sacro-iliac synchondrosis—symphysis pubes foramen ovale—acetabulum—linea ileo pectinea—the false and true pelves. 2.—The relative position of the uterus, bladder, rectum, blood vessels, and nerves to each other and to the pelvis—the situation of the meatus urinarius—mode of introducing the catheter—perineum. 3. The measurements and diameters of the brim of the pelvis, especially the antero, posterior, transverse and oblique—the measurements and diameters of the outlet. 4. The form and structure of the child's head—the anterior and posterior fontanelles—the sagittal suture. Its measurements and diameters, especially the longitudinal, occipito-mental or oblique, and the transverse. 5. The mechanism of labour—the necessity of there being an exact adaptation of the various diameters of the head to those of the pelvis. 6. The situation of the head in the first stage of labour—the mode of its transmission, particularly that given by Naegelè—the situation of the head at the outlet. 7. The obliquity of the pelvis in relation to the spinal column—the axis of the brim—the axis of the outlet—the necessity of the propelling power being in the direction of the axes—the necessity of placing the patient in labour so that the axis of the uterine cavity may correspond with that of the brim—the impossibility of safely using any extracting force but in the direction of the axes. 8. The position of the uterus just previously to the commencement of labour—the nature and manner of uterine action—the state of the os uteri in the first stage—its situation—the means made use of by nature for its dilatation—the necessity of not unnecessarily interfering with this process. 9. The character of the pains in the first stage—the change which takes place in their character, in the position of the head, and state of the os uteri during the second stage. 10. The best mode of applying support to the perineum during the expulsion of the child. 11. The need of knowing that there is not another fœtus in utero before any attempt be made to extract the placenta. 12. The best kind of bandage, and the best mode of applying it. 13. The time and manner of extracting the placenta, and the necessity of ascertaining the condition of the uterus before attempting it. 14. The time and mode of tying securing and dividing the umbilical cord. Lastly:—The necessity of being perfectly satisfied that the patient is safe before he leaves her.

Modified variola after vaccination.—Mr. Blackall of Henry Street, Avenue Road, Regent's Park, has forwarded us the particulars of a case of modified variola after vaccination. A strong healthy child, aged two years, of full habit was vaccinated by him, and the arm shewed no tendency to inflame before the 5th day; on the 6th, it presented the usual appearance resulting from the application of the vaccine lymph; on the 7th, there was high fever with convulsions added to which, the child appeared to suffer from teething. On the 8th, a vesicular eruption was thrown out on the lower extremities, back and face, but without any abatement of the constitutional disturbance. On the 9th, the eruption was more numerous, but still thin and partial, but no convulsions, and less fever. On the 11th, the pustules on the face seemed fuller and better formed, and in a few instances shewed the pit or central depression attendant on variola, but this distinguishing symptom was confined to a few pustules, and was very indistinct; a few days after desquamation took place very favourably. In some concluding remarks on this interesting case, Mr. Blackall draws attention to the peculiar circumstance that, on the fifth day from the time the child was vaccinated the puncture of the arm inflamed, and on the sixth the pustule was distinct, and presented the usual appearance of a successful and well defined vaccination, previously to which no eruption was visible on the body, face, or limbs. The fact of the vesicular eruption appearing after, and not before the pustule of the arm rose from the application of the "vaccine lymph," would lead one, he says, to conclude the vaccination succeeded; but the strangeness of the eruption, and the constitutional excitement that followed, coupled with the other facts of the case, made it highly improbable. He then enquires why did the puncture of the arm first inflame, and arrive at the pustular form of the complaint if the vaccination did not succeed? and if it did, how and why did the variolous disease shew itself, and whether a scratch or wound on any part of the body would give a preference to the latter to shew itself in that identical part when small-pox arose from natural causes? and if a person labouring under an undeveloped attack of variola was vaccinated while under its influence could it so modify and alter that disease as to produce the varied form of it which he has described? or could it neutralize the efficacy of the "vaccine lymph," and predominate and attack the part primarily at the point where the puncture was made for vaccination.

TRANSACTIONS OF LEARNED SOCIETIES

Royal Medical and Chirurgical Society, April 22nd 1845, Dr. Watson, Vice President, in the chair.

Two cases of Formation of Artificial Pupil, with the Description of a New Instrument for Seizing and Detaching the Iris, by Wm. R. Beaumont, Esq., Professor of Surgery, in the University of King's College, Toronto, Upper Canada, &c.

In bringing forward these cases, the object of the author was to present to the notice of the Society, a forceps which he has invented for seizing the iris, and detaching its ciliary margin from the corpus ciliare, or for drawing any portion of the iris through a wound in the cornea. After noticing the instruments used in these operations, and particularly the fine hook which is recommended by Mr. Lawrence, he remarks that the hook sometimes tears its way out of the iris, instead of detaching it; but in using the forceps suggested by the author, this laceration of the iris without its detachment never occurred, and he never failed in any instance in seizing the iris at the first attempt, and close to its ciliary margin. The hook may possibly in transfixing the iris, wound the capsule of the lens; the teeth of the forceps are too short, and are set in a direction which causes them to enter the iris obliquely. The point of the forceps when the blades are closed, is perfectly smooth, the teeth being then concealed, so that the instrument may be introduced into the anterior chamber without risk of wounding any other part, than that portion of the iris which it is the intention of the operator to seize. After giving directions as to the mode in which the instrument is to be used, the author concludes his paper by narrating two cases. One was a case of leucoma with contracted and adherent pupil, in which an artificial pupil was formed by the detachment of the iris from the ciliary ligament. Vision afterwards gradually improved, so that the patient was able to maintain himself by his labour; before the operation he could only distinguish light from darkness. The other was a case of central leucoma of the right eye; the pupil elongated toward the temple by a previous operation for artificial pupil. An artificial pupil was formed by detaching the iris from the upper part of the ligamentum ciliare, and by the excision of some of the detached portions of the iris. Vision was so much improved by the operation, that the patient was able to read large print and sharpen the teeth of his saw.

Mr. Cæsar Hawkins observed that he thought the cases which had been narrated by Mr. Beaumont were not of a character to induce surgeons in this country to avail themselves of the instrument in operating. It appeared to have been successful in only one of the cases; in the other, the instrument became entangled in the iris, and required a further operation for its extraction.

Case of remarkable hypertrophy of the fingers in a girl, with a notice of some similar cases; by T. B. Curling, Esq. Lecturer on Surgery, and Assistant Surgeon to the London Hospital.

Eliza Hitchcock, aged 15, the subject of this congenital malformation, is a pale sickly girl, the

daughter of poor parents. On the right hand, the fore, middle, and ring fingers are of unusual size. The enlargement of the fore and ring fingers is only slight, but the middle one is of extraordinary proportions, measuring as much as five inches and a half in length, and four in circumference. On the left hand, the thumb, index, and middle fingers are hypertrophied. The index finger which is most enlarged, measures five inches and a quarter in length, and four in circumference. The middle finger has a lateral inclination occasioned by the displaced extensor tendon, which forms a bridle along its outer edge. All parts of these hypertrophied fingers are equally developed in excess, the bones, articulations, integuments, and nails. The two largest fingers are fixed in an extended position, and the author attributes the girl's inability to bend them to the flexor muscles not having acquired a development corresponding to the fingers upon which they act.

The author observes that in this remarkable example of partial hypertrophy, there is an apparent absence of all those circumstances which seem favourable to excessive growth; a feeble constitution, sparing nutriment, no extraordinary exercise of the part, and no enlarged vessels or activity of circulation. It would seem as if the formative powers which we see in some few cases exercised to excess in every part of the frame so as to make a giant, had been limited in this instance to an insignificant part of the extremities.

The paper contains a communication from Professor Owen giving an account of a case analogous to the preceding one. The subject was a child two years old. The middle finger of each hand was nearly twice as long, and more than twice as thick as the index finger.

The author gives the particulars of a hand, the cast of which was sent him by Mr. Diamond of Frith Street. It is from a Spaniard, the Governor of a fort in the Philippine Islands, and presents congenital hypertrophy of the first and second fingers of the right hand. The second which is of enormous size, had the same kind of lateral inclination, as was observed in one of the fingers of Eliza Hitchcock. The author also describes a cast contained in the Museum of King's College, London, of the hand of an adult, in which the middle finger is hypertrophied with a slight lateral inclination.

The author after noticing the rarity of this malformation, refers to two published cases of it; one recorded by Mr. Power of Dublin; the other by Dr. John Reid. In the former the fingers were divaricated from the middle. In all the four foregoing cases in which the hypertrophied fingers bent to one side, the author suspects that the inclination was produced as in the case of Hitchcock, by the tension of the displaced extensor tendon, which had not elongated in proportion to the increase in the size of the finger.

The author notices whether it be possible by any mode of treatment to arrest the inordinate growth of the fingers in early life. He doubts if this could be accomplished by any other method than by firm and long-continued pressure, but in addition to the suffering attending it, the impairment of the functions of the part caused by the pressure, constitutes an insuperable objection to its employment. In a case in which only one finger to a great extent is enlarged, and nearly useless, he recommends its removal. In other cases, the enlarged finger might be reduced in size by amputation of the distal phalanx.

The paper is concluded by a brief notice of two cases of hypertrophy of the toes.

Description of a Malformation of the Duodenum.— by Robert Boyd, M.D. communicated by Robert Lee, M.D., F.R.S.

This morbid specimen was from a male still-born infant; the duodenum was enlarged, and appeared like a bladder two thirds filled, and contained a greenish coloured fluid. The lower, or most distant part from the stomach, was imperforate, and of larger calibre than the upper part, so that the malformed duodenum as exhibited in the preparation, is somewhat of an oval shape. The intestine is completely closed by a transverse membrane at the lowest part; two inches and a quarter above this, a valve extends across, nearly half closing the gut, proceeding from its concave side. Around the membrane which closes the duodenum, the small intestine is attached, and when dried and distended with air is only about the thickness of a writing pen. The author, in conclusion, refers to various writers who have given an account of similar divisions and other malformations of the intestinal canal.

A case of Abscess in the Groin attended with symptoms of Hernia, from which two Lumbrici Teretes, and afterwards fæcal matter were discharged, and the patient recovered, by Thomas Howell, Esq., of Risborough. Communicated by Alexander Shaw, Esq.

John Stevenson, aged 70, was attacked with symptoms of strangulated hernia. The author found a small tumor, about the size of a hen's egg, in the right inguinal region, lying over Poupart's ligament, about midway between the internal and external abdominal rings. At first he supposed it to be a hernia, but on careful examination could detect no impulse on coughing, nor could he find a neck towards the internal ring; the tumor was not in the precise situation of inguinal hernia, and he was therefore led to conclude it was an enlarged inguinal gland. The symptoms were relieved by calomel and opium, and a dose of castor oil, which acted freely; after two or three days phlegmonous inflammation took place, and on fluctuation being perceived, the part was opened, and four ounces of pus discharged. On the poultice being removed next morning, two worms, (*lumbrici teretes*) each from five to six inches long, were found in it. After that, feculent matter continued to escape from the wound for three weeks. He also passed fæces per anum, but not of so bright a yellow colour as from the groin. The discharge from the wound gradually diminished, and in five weeks the author succeeded by means of pressure in healing the orifice. The patient stated that he never had hernia.

Mr. Cæsar Hawkins said that there was one point which he could not allow to pass without observation, especially as it had been a cause of error in other instances. He alluded to the diagnosis which had been formed by the author after an examination of the tumour, which, as it appeared to him (Mr. Cæsar Hawkins), he was led to regard as not being a case of strangulated hernia, because there was not any impulse communicated to the hand on coughing. This, with him, would have been a reason for believing in the existence of strangulated hernia, because, in nineteen cases of twenty, the strangulation of the intestine removed the impulse on coughing, which occurs generally, only when the gut is not strangulated.

Dr. Chowne had seen a case, some few years since, which he thought bore some analogy to the case which had been narrated by Mr. Howell. The patient was affected with obstinate constipation, to whom, after other remedies had been tried, and had failed, a quantity of mercury was administered. A tumour formed subsequently in the groin, sloughed, and from two to three ounces of quicksilver were discharged. The case was attended with similar symptoms to those which were met with in Mr. Howell's case, and had also a similar result. He thought the case was very unusual, to say the least of it.

Mr. Arnott recollected a case, which had occurred a few years ago, in the Middlesex Hospital, in a young girl, who had an abscess in the right side, in the same situation as Mr. Howell's patient, and which sloughed, and discharged fæcal matter. The girl ultimately did well. He had thought that the circumstance, with reference to diagnosis, which had been alluded to by Mr. Cæsar Hawkins, was one that was generally known to the profession. He himself had pointed it out to his pupils in a case which he had operated on, a week or two before. Abscesses in this situation, are often a source of great annoyance to the practitioner. He (Mr. Arnott) was called in consultation, some time since, by a gentleman, to such a case, in which the surgeon was apprehensive of having made a mistake. There was a tumour in the left groin (a rather unusual circumstance, as these abscesses generally form on the right side), which, from the want of impulse on coughing, he concluded, was not a case of strangulated hernia, and was induced on the supervention of redness, and evidences of fluctuation, to put in a lancet, on doing which, however, and giving issue to fæcal matter, he became alarmed, and in the belief that he had opened a strangulated hernia, sought for an additional opinion. The case proved to be a simple one of fæcal abscess, and the patient ultimately recovered.

Case of Traumatic Tetanus successfully treated by large quantities of wine, brandy, and other means. By James William Scott, Esq., of Bromley, Kent, communicated by James Arthur Wilson, M.D., Physician to St. George's Hospital.

The patient, a robust man, ætat. 30, was thrown from his chaise, Nov. 28, and met with a compound fracture of the tibia and fibula, and considerable injury to the soft parts. By extension, the bones were placed in a good position, and it was determined to save the limb. The patient went on remarkably well, till the 12th of December, when tetanic spasms first commenced. Healthy granulations had formed, and were covering the denuded bone. The spasmodic action affected the muscles for a time and then gave way, the muscles of the jaw being those chiefly affected. On the 14th, he complained of cramp and spasm in the chest; a blister was applied, and calomel and cathartic medicine were administered. 15th. The pain and spasms of the chest were somewhat relieved, but he was very weak. He was ordered brandy and water, and medicine with ether, every two or three hours, after which he somewhat rallied. He continued much the same till the 18th, when the tetanic symptoms were much increased in severity, and in the evening there was opisthotonos. Mr. Scott saw the patient, and agreed in the propriety of continuing the stimulants, and suggested opiate enemata, and ol. terebinth. and ol. ricini internally. This treatment was pursued with little variation till the 21st, when he was observed to be extremely low, with a pulse about 40, and in a cold, clammy perspiration. The quantity of brandy at this time administered, amounted to rather more than three pints in the 24 hours. Every part of the muscular system seemed affected with spasm.

Dec. 23rd, he was much the same, but the wound was looking more healthy. Dr. Wilson saw him, and urged the continuance of the stimulants, but recommended the entire discontinuance of the opiates. He also recommended a suppository composed of quinine, sesquicarbonate of ammonia, and camphor, to be administered every three or four hours. From this period he continued to improve, and on the 26th, all tetanic symptoms had disappeared. During the eight days in which the disease was at its height, the patient took two gallons of brandy, besides wine, beef-tea, jelly, &c. Jan. 29th, the wound was nearly healed, and he was daily gaining strength.

In a supplement to this communication, Dr. Wilson remarks, that the case affords a well marked case of traumatic muscle-fever, and that the principle on which it was treated was one of unremitting stimulus and support, opium, and all other narcotics, being entirely laid aside on the tenth day of the attack.

The extent and severity of the constitutional disorder were strongly indicated by the patient's indifference to all the ordinary effects of the alcoholic stimulus. From this case he draws the important pathological inference that tetanus, like fever, is a disorder of the entire system. Determined specially to the muscles, it is continually operative in the other structures, as in the universal blood. Generated after a definite period of incubation, it requires time for its development, time for its cure. On these views and indications, that treatment that assumes to be rational must address itself to the general business of nutrition, rather than to the partial agencies of the nerves. Under the great systematic error of our modern pathology, tetanus is encountered almost exclusively by opium and other narcotic poisons. There is no plausible theory to account for the

preference of these fatal drugs. By experience, they have long been utterly condemned.

Mr. Davis of Hampstead, was much astonished at the concluding observations of the paper condemnatory of the use of opium. He had seen a great many cases of traumatic tetanus, the result of gun-shot wounds; and he felt convinced, that if he had not had any opium at his command, many men of his acquaintance would not now be living. Small doses of opium, however, were of no use; he had given as much as a scruple at a time, and frequently administered ten grains at a dose, repeating it from time to time as it was required. Opium, in his opinion, was our sheet-anchor in the treatment of this disease; opium and carbonate of ammonia were the principal remedies to be relied on. The unguentum hydrargyri had certainly been rubbed into the system in his cases, but he believed that the other drugs were principally efficacious. He had seen many cases of tetanus which had been cured by opium alone.

Dr. King referred to two cases of tetanus which had been successfully treated by Dr. Sutton, of Greenwich, by the external use of a solution, containing a pound of opium. He (Dr. King) had essayed this plan of treatment in the case of a lady labouring under traumatic tetanus, and had certainly relieved the disease, all the symptoms of the tetanic character having ceased, but the solution of opium was so powerful, as to cause deep sleep, and the cessation of the heart's action, and the consequent death of the patient. He regretted that, from the deep sleep in which his patient lay, he was unable to exhibit stimuli, as, had he done so, he believed she would have recovered. He recollected, when in the country, having seen two cases of tetanus in the horse, which were cured by the use of tobacco enemata.

Dr. Snow thought that the case which had been detailed in Mr. Scott's communication was different from ordinary cases of traumatic tetanus. The disease, when it did occur, generally came on soon after the receipt of an injury, whilst the stamina of the system were not much impaired; whereas, in Mr. Scott's case the patient's strength must have been exhausted by the long continuance of the pain, and the excessive discharge of pus. The attack of tetanus began by simple spasmodic twitches, a result, as he thought, of debility, and therefore the treatment which had been adopted was the best that could have been employed. He had recently seen a similar attack of spasmodic twitching in a patient whose strength had been previously reduced by rheumatism. Although he approved of the treatment in this case, he was of opinion that further experiments were required, ere its employment could be admitted as generally available in the treatment of tetanus.

Mr. Blizard Curling observed, with respect to the case which had just been read, that he was disposed to give the greater part of the credit of its successful treatment to Messrs Scott and Ilott, who had conducted their patient through the most dangerous part of the disease, inasmuch as it is generally admitted that if the patient survives till the tenth day, he will in all probability, do well, and it appears from the paper that there was not any important alteration made in the treatment up to that date. He had seen a case of tetanus in the London Hospital, under the care of one of his colleagues, which was quite as severe as the case narrated by Mr. Scott, and which was successfully treated on the stimulant plan. In a work on tetanus which he published about ten years ago, he (Mr. Blizard Curling) stated that he had not any confidence in opium, and he had not since had occasion to change that opinion. In the same work he had suggested the use of stimulants&c in the treatment of this disease, on the ground that it was a complaint which tended to exhaust the powers of life, and he believed that in some instances, life was lost for want of the requisite support.

Mr. Solly had happened to have three cases of tetanus recently under his care, the cases occurring very close upon each other. Two of these terminated fatally; the other recovered, and he was inclined to attribute the successful result of the last case to the free exhibition of stimulants, which was continued night and day, by the intelligent sister of the ward. He (Mr. Solly) fully concurred in the opinion that the use of opium in this disease was prejudicial.

Dr. Jeffreason was of opinion, that the remarks attached by his old teacher, Dr. Wilson, to the communication which had just been read, materially increased its value. He had seen several cases of idiopathic and traumatic tetanus, and had found that the treatment must be modified according to the circumstances of the case; in some instances, purgatives, in others stimulants proving advantageous. The rule was, he thought, to treat the disease as one of fever, and not to depend on the action of any specific remedy. He, (Dr. Jeaffreason,) quite agreed with Mr. Davis, that in the exhibition of opium, large doses alone would be effectual.

Mr. Simon observed that in tetanus, the disease was reflected on a single system of the body from a local cause, and he thought, therefore, that it should not be considered as a malady, directly affecting the general economy. The functions of life and of the nervous system were unimpaired, and the intellectual faculties generally remained intact to the last. The utility of the exhibition of stimulants and tonics in the treatment of this disease, might, he believed, be interpreted, by the support they gave to the powers of nature, thus enabling the patient to outlive the disease, and not by any specific action they exerted against the poison of tetanus. Their influence was expended in enabling the sufferer to bear up against the disease, until the cause which produced it was worn out, and then the tetanic attack naturally came to its termination. This is more evident in chronic cases of the disease, such as that under notice. If we do indeed possess any remedy, entitled to be called anti-tetanic, it is tobacco, which, by relieving the spasmodic action, and diminishing the general severity of the attack, affords time for the exhibition of such other remedies as may enable the patient to struggle through, until the disease is terminated by the efforts of nature.

Dr. King stated, that in the case in which he adopted the plan of treatment employed by Dr. Sutton of Greenwich, there followed a cessation of all the symptoms of tetanus. This again was succeeded by deep sleep, which proved to be the sleep of death, for his patient died three hours afterwards. He regretted much that he was not able to administer stimulants, by the use of which he believed she might have been recovered. The external application of the opium solution, in this instance, produced its full sedative action.

Mr. Streeter enquired how many hours elapsed after the application of the opium had been made, before sleep was induced, and further, how long a time passed away after the patient fell asleep, before death took place.

Dr. King, in reply, stated that he saw the lady at twelve o'clock at night, and then gave her a glass of wine. She died at three in the morning. A pound of opium was made into a plaster, and was applied for four-and-twenty hours.

Mr. Streeter was inclined, in this instance, to refer the cause of death to the poisonous action produced by the external application of so large a quantity of opium.

Mr. Cæsar Hawkins alluded to the plan adopted by Dr. Wells in this disease,—that of the do-nothing system.—Like all other vaunted plans, it was stated, that under that system also, the patients had recovered, (laughter.)

Dr. Watson remarked that in the paper, special allusion had been made to the curative influence of the element of time.

Ethnological Society, April 23rd, Admiral Sir Charles Malcolm, President in the Chair.

Major General Briggs, Richard Cull, Jonathan Rigg, Albert Gladstanes, David Wilson, and Richard Bayley Esquires, were elected Members.

Dr. King then read a paper "On the human mouth" by Mr. Nasmyth. "Was mankind originally of a low or of an elevated degree of development?" enquires Mr. Nasmyth, and he answers, the development compatible with the due fulfilment of the exactions required from such a being as man must have been perfect. No feature bears so instructively on the solution of the various difficult problems involved in the study of ethnology as the form of the mouth, and the development of the teeth. In the lower animals the mouth is peculiarly and beautifully adapted to their exigencies, but in that of man exists a medium type fitted to every peculiarity of terrestrial existence. No other conformation than that given to him, can at once admit of perfect articulation and mastication of his varied food; moreover it may be regarded as fulfilling a most essential part in his intellectual life, for it is the organ of intellectual expression, and a grand agent in the communion of social life. Deviations in the character of the mouth, Mr. Nasmyth contends, are simply the effects of deviations in the habits of individuals composing races. When these deviations are partial, they are shown in individuals, when general, they amount to a national or tribe characteristic, and when continued from generation to generation, they become hereditary. The natural action of the lower jaw upon the upper is to push out, evert, or expand, the arch of the upper jaw, while on the other hand it is impossible by any habit to bring in or to contract that arch, so as to produce out of the advanced jaw of the negro the vertical jaw of the Caucasian and other well developed races; a vertical is said to be the original development of the infant negro; the advanced mouth of the adult negro is therefore not congenital but factitious. The negro of the southern provinces of the United States, owing to the different circumstances in which he is placed, has not the advanced mouth of his progenitors of Africa, after the 2nd or 3rd generations. Mr. Nasmyth then proceeded to show most ably that the plasticity of the mouth in infancy, was such as to admit of the factitious development pointed out. The ordinary duties required of the mouth in civilised life are a moderate exercise of power for division, tearing, and comminution or grinding, whilst in uncivilized life there exists much more powerful exactions, which have a great controlling influence over the development of the parts. Man in the uncivilised state has but few instruments or tools to assist him in operations of any kind, and his teeth are ready substitutes for those, which on all occasions from infancy to old age, he most inscrupulously resorts to. He attacks the roughest materials of all kinds with his teeth. He uses them to form and to fashion those materials in all sorts of ways; and thus he converts the dental organ into a prehensile one. He also uses his teeth as instruments for punishing his enemies, seizing his prey, and separating the assimilative portions of his food from those which are not, which with the little assistance he derives from cooking, tend most decidedly to evert both the upper and the under jaw. Mr. Nasmyth explained at length various modifications of the face, arising out of the eversion of the upper jaw so common in uncivilized life, whilst in the civilized, a perfect organization of the mouth was pretty generally accompanied by a well developed brain, a regularity of feature, great energy of character, and corresponding physical power and activity. * After the reading of this paper which was as elaborate as it was important, as affecting materially the existing classification of mankind, Dr. Wolff addressed the society on the Asiatic Tribes of his acquaintance, the Turkomans holding a prominent place.

Society of Arts.—March 12th.

A paper was read, describing a machine invented by Mr. Tomes, surgeon-dentist to the Middlesex Hospital, for making artificial teeth and palates. The machine, which was exhibited then, and subsequently at the Royal Society's *Soirees*, is a form of copying instrument, fitted for working in hard substances; and from the rapidity of its execution, together with the great faithfulness with which it copies any undulating surface, it seems likely to

---

* A point insisted upon by Mr. Nasmyth is, an irregular development of the mouth from a suspension of its use, which tends to produce destruction of the teeth and sockets.

supersede, to a considerable extent, hard labour in making artificial teeth.

In the paper, an account was given of the usual manner of working. First, a plaster of Paris cast is taken of the gums to be fitted with teeth. If hippopotamus teeth be chosen as the material (and the author gave reasons for considering this the best,) a block is taken of sufficient size; the cast is then covered with paint, and the block is placed upon it; on removal, the block will show the points where contact has taken place, by the paint which has adhered to it. These points are cut away. The operation is repeated a great number of times, till the block fits the surface of the cast. As this manner of working requires considerable expertness, both in the hand and eye, as well as time and patience, great accuracy in fitting the block to the cast is in many cases not gained; and to this defect the author ascribed the inconvenience which is often complained of by the wearer of artificial teeth. A method of testing the accuracy of the plaster cast, previously to commencing the work, was pointed out which is also new. The plaster cast having been taken in the usual manner, a peculiar hard wax, or moulding composition is, when treated by boiling water, pressed upon the cast; when cold it is removed, and cut into the shape of the proposed artificial teeth, forming, in fact, a model of the new teeth. This is placed in the mouth of the patient, and if the cast be accurate will fit perfectly; but if the cast be untrue the fault will be discovered by the model not fitting the mouth.

If, however, the composition model fits perfectly, a copy is made from it in hippopotamus, or other teeth, by the aid of the machine, and so singularly accurate, that were the model and copy of similar material, it would be difficult to distinguish the one from the other.

If gold be used for the base of the teeth, then the masticating teeth are fitted upon its surface by the machine.

The body of the machine is made of cast iron, and consists of two planes, which are united at a right angle, leaving two large surfaces at right angles. These planes are placed vertically and horizontally.

Upon the vertical plane are two slides, which carry a flat plate of metal in two directions, namely, vertically and horizontally, each motion being in the vertical plane. Upon this so-moved plate are placed, side by side, the composition model and the substance to be worked, the two being on one plate, and receiving motion only through that plate, must move exactly alike. A third slide is placed on the horizontal plane of the machine, and moves horizontally, but at right angles, with the two motions of the plate which carries the model.

Upon the third slide are fixed, parallel to each other, a tracer with a rounded point and drill, which, when in motion, describe an exactly similar shape and size.

The drill being set in motion by a foot wheel and over-head motion, similar to that of a turning-lathe, the tracer, by the sliding movement, is made to follow in consequential lines the surface of the composition model, while the drill partaking of similar motion, cuts in the substance placed before it, a surface similar to that described by the tracer, and in doing so, produces a fac-simile of the model. Various mechanical contrivances were described for economising time, and rendering the machine complete, which would not be understood without the assistance of a plate. The machine is constructed to produce a reverse, but this part not being essential for the dentist, was not dwelt upon. The invention is of great importance in forming substitutes for loss sustained about the organs of mastication and articulation, and may be found useful in remedying other surgical losses.

Professor Liebig according to a Liverpool Journal, has taken out a patent for some artificial manures suited to various kind of crops produced by different soils. Mr. Muspratt the eminent capitalist of Liverpool is associated with Liebig in this important mercantile speculation of the German Philosopher.

NOTICES TO CORRESPONDENTS.

☞ *Subscribers to whom bills have been sent are requested obligingly to forward their remittances. By paying in advance for the year, a saving is effected to them, and much trouble about accounts spared to us.*

Mr. H. *should himself look to his accounts. No items should have been allowed without vouchers; and the declaration of the auditors should distinctly have been made public.*

D. F's *Letter contains personal charges unsuited to our pages.*

Many obliging communications on the action brought against us by Mr. Wakley have come to hand. The writers are requested to receive our best acknowledgments, and again we have to express our hope that our friends will reserve themselves, till the result of the Inquiry become known to them.

H. B.—*Hair dyes from the German have been given in former Nos. of this Journal.*

We have received an original communication from Professor Piorry of the Faculty of Medicine, Paris, which shall have a very early insertion.

Contributions have also been received from Mr. Braid, Manchester, Mr. Anderson of Leicester, and Dr. Clay. Other papers kindly sent to us are under consideration.

Mr. Harris *thus addresses us.*—

Redruth, Cornwall, 24th April 1845.

"*I beg as one of your numerous readers, to ask if a person who passed the College of Surgeons about two years ago, and who about the same time was rejected at the Hall, will be allowed to register as a general practitioner under the new Bill?*

"*The whole county of Cornwall condemn the recent monopolizing Charter granted to the College.*

"*And every medical man has the utmost confidence in the proceedings of the National Association of General Practitioners. Our county motto is 'one and all,' and we will maintain the sentiment of our loyal motto, in a medical sense." The M.R.C.S. not a L.A.C. will be allowed to register as a General Practitioner by the new Bill."*

B. *has misunderstood us. All the lists are carefully published, though an occasional delay will, of course, necessarily arise from circumstances familiar to all connected with the management of a journal.*

A Regular Subscriber.—*It would be illegal and irregular.*

A Poor Student *need not be alarmed. The alteration suggested will be made in the Committee. We shall not overlook the circumstance however.*

A Subscriber *may possibly derive some benefit by entering himself* "perpetual" *to all the courses in one of the medical schools. The date would be, of course, in his favour. But nobody can yet say what shape the Bill will finally assume.*

"An Apothecary" *is too long for admission; but we avow that we were wholly unprepared for the handsome act of corporate self-denial performed by the Apothecaries' Company. It stands in splendid contrast to the besotted bigotry and insane obstinacy of the College of Surgeons. We are sure the spontaneous and generous abdication for the good of the Profession, will not be overlooked by those whose interests it will so well serve. Nothing in this life, it will be again said, so well became them as the manner of their quitting it.*

Dr. Roche Lynch's *circular has reached us. It omits to say* by whom *the accounts were audited.*

Argus.—*Adverts to Clause 32 in the Bill and complains of the obscurity as to who is a "legally practising" surgeon; and what are to be the satisfactory proofs of the fact that are to be submitted to the Council of Health. The London Surgical Diploma confers no legal right, not common to all her Majesty's subjects.* Argus *foresees great inconvenience from the Bill's incertitude in these points, many medical men now acting as surgeons, who, if the obscurity be left uncleared, cannot register as surgeons.*

M. D. K.—*The Bill is obscure on the point.*

Justitia. *Arago gives four kinds of lightning.*

H. B.—*Present the Bill to the Magistrates in Quarter Sessions.*

A Surgeon.—*The College is on the high road to ruin. The Fellowships are* not *worth purchasing. There is a power in the National Association, no minister, while he has a Bill in the House, can resist. The new college will absorb every thing, if the same course of independence and freedom be persevered in.*

THE MEDICAL TIMES.

Saturday, May 3rd, 1845.

I, this infer:—
That many things, having full reference
To one concert, may work contrariously,
As many arrows loosed several ways,
Fly to one mark.
Shakespeare.

The bill is undergoing another tinkering, and on Monday evening, if we are lucky enough to have a house formed, we shall be able to see whether the ill-fated measure will, after all, hold water. During the eclipse of the sun a certain breed of Africans, who believe that he is devoured by some heavenly animal of huge appetite, compel the monster to disgorge their lost luminary by a very continuous clangour of instruments and clamour of voices. During the occultation of our unfortunate Bill, a little noise from our editorial rattle may be of almost equal service. The order of things political may be as much under our influence as that of nature under the impulsion of our darker brethren,—a very consolatory reflexion.

The great leak in the Bill—the *hiatus valdissime deflendus*—is the omission to provide for the General Practitioners in their relation to the College of Surgeons. Now the tinkering that will set this right must be applied with no sparing or hesitating hand. No *gentle* touches of the legislative hammer, however skilful—no "soft sawder" of a smooth-tongued secretary, however bountiful—will reach the mark. If Graham will not dare the bold and handsome thing, he may as well give up the "*job*" at once. His first tinkering proved the new measure bad; his second showed that his mendings were failure; and if he try a third with no better luck, it will be time to bethink him of marching out of office. A legislator that makes ill and mends worse may have the confidence of Peel, who wants a foil, but not of men who cannot afford to be kept in hot water from one holiday to another—from session to session. Patch on then, Sir James, if it please you to patch honestly,—boldly,—and completely; not otherwise.

Had we the settlement of the dispute between the Council and their Members we should proceed somewhat in this fashion:—The whole struggle is, whether or not, in a College of twelve thousand equal Members, a peculiar set of Surgical Practitioners, about four hundred in number, shall *monopolize* the honours, privileges, patronage, and government of the Institution. Obviously such an insulting ascendancy is unjust as it is impolitic and permanently impracticable. It is wrong of itself, that ten thousand gentlemen because practising surgery in connection with pharmacy, (we will not say midwifery, for that *is* surgery) should thereby be excluded from those distinctions in their own College which their *surgical* merits singly would have secured them. If the Jacksonian prizes in Surgery were so illiberally restricted, the most worthy competitor of this year, Mr. Crisp, a General Practitioner, would have had his brilliant labours discouraged for the illicit patronage of some less able "pure;" and it is clear that the College that in any fair part so trammels its Members' exertions, retards and impedes the science it should aid and expedite, and forgets the first great end of its being for petty personal considerations. Cutting off thousands from the ennobling stimulus of competition.

and turning the select few, more highly favoured, into sycophantic place-hunters or apathetic functionaries, it leaves science to the chance cultivation of the naturally enthusiastic. The exclusiveness is, therefore, simply infamous. Besides, on what decent plea can the Member of a Surgical College be placed under such disabilities? The Council that would deny him the *honours* gave him the *title* of the "surgeon." The Council which would withhold the *privileges*, present him the *rights* of "*Membership.*" At their own absolute discretion they fixed his surgical curriculum of study; they adjusted, after their own notion of right the standard of his surgical qualifications: they (charged with the *uncontrolled* duty of testing his surgical competency) deliberately examined and formally certified to the world, that he was "fit and capable to exercise the art and science of surgery;" and having thus made him, at *least* as good a surgeon as they liked, at least as competent a surgeon as they thought society required, charging him as much for his new membership with them, as they were charged themselves—they cannot be allowed to go back shamelessly from their bargain and say to the legislature, "We did not perform our duty fully: degrade these gentlemen for us. True, we educated them as surgeons, examined them as surgeons, authorized them as surgeons, drew fees from them as surgeons; but we still assure you they are not surgeons! We that made them Members of the College, deny them, even to our own ignominy, the rights of Membership." What is the answer? This: "Gentlemen, if you, fixing at will the terms of worthy Membership, declared them worthy Members when *they* held their fees, we can recognise from you no objection to the worthiness of that Membership now that you have got them. Your own act precludes your objection. *You* have had the advantage of their money—some ten thousand a year—*they* must have the advantage of that for which it was paid. They may be physicians, apothecaries, accoucheurs, or a hundred other things—but by your own unanswerable shewing they are "able and competent surgeons," approved Members of your Surgical College, and as long as they are so, so long must they have a fair participation in the rights, privileges, and powers belonging to their corporation. As you cared nothing what they were, if surgeons, when they asked privileges for fees, you must care nothing what they are besides, now that they come forward to *exercise* privileges for fees. If you like not the result, you should have made a different arrangement. You cannot be paid for your surgeonships, and recall all that they carry with them."

All being, thus, members (by every usage and compact, *equal* Members) *all* being, thus, surgeons, —all having undergone *equal* studies and examinations, and paid equal fees—no difference in fact existing, in a *Collegiate* view of things, but in natural ability, good fortune, or some contemptible variety of practice, the first great step to a remedy in our mind—and let Sir James think on it—is to re-model the recent Charter, to again put the Members on a perfect Corporate level; to give them full and honourable Corporate privileges, and as it is more gracious to rise than to fall, to constitute *all* Fellows. If gentlemen are unworthy to be Fellows, they are unworthy to be Members, and let the statute which re-establishes the old equality, weed the College of all those disreputable characters whom the careless or undiscerning Council have given it. The Members being thus replaced in a natural, comfortable. Corporate position of equality, it would appear to us a foolish carefulness of precaution which would confine the elective privelege to any division of the Members, and constitute the enormous evil of invidious distinctions and antagonistic grades for an end so very trifling. All Members registering their addresses each year, and residing within the three kingdoms, should, on the occasion of a Councillor's election have voting papers transmitted by post, and their return, through the same medium, would be conclusive as to the Member's suffrage. The whole process of a dignitary's election might thus be as simmple and placid as the decision of a Jacksonian prize, and if Surgeons had really not the taste to appreciate the worthy men of their own body, so much the worse for themselves. They might in that case be more discredited than now, certainly not worse governed. The present Council might not unreasonably be required to relinquish the offices they have so ill-filled (so many (three?) each three years); but we believe if the simple plan we have sketched were adopted, the body of Surgeons would not object to the retention of their life interest, especially if their numbers were added to in about an equal proportion. The plan we submit is thus plain, simple, and just, and really does nothing to frighten anybody. The College of Surgeons *should* exist for its *members* who are, in fact, *the* College. The Members *should* govern the College, and elect their own rulers. The governing body *should* exist for *them*, not *they* for the governing body.

Now this just, practicable, and reasonable arrangement, would *save* the College, and nothing else will. Vain is the hope that the opposition will run itself dry. As soon will the Thames. At this moment the Profession is in its hour of strength and knows how to use it. The College must be given to its members, or the members will destroy it by another. Sir James Graham has four courses before him—of which two alone can be successful. He may refuse everything—which will be dangerous. He may make a small compromise—which will be useless. He may make the College of Surgeons a National Institution which will please everybody, save some dozen or two placemen and their hangers on. And, finally, on the ruins of the Apothecaries' Company, and by the aid of the coalesced Medical Associations, he may build up a National Faculty in which no worthy medical man shall be alien, and in which worth shall be the touchstone of honour and great incentive to exertion. Of the two last plans, though substantially not very dissimilar, many might dispute which is the more perfect, especially after the Council's madness, and the honourable voluntary retirement of the Apothecaries' Company. But all will concur in this, that either would be an infinite improvement for the profession.

We await with much anxiety, the result of Graham's conference with the six gentlemen appointed as the profession's "plenipotentiaries," at the Home Secretary's request, to negotiate, on the part of the Association and the Apothecaries' Society, the conditions of the new incorporation. The result will be fully divulged at the meeting of the Association, on Tuesday evening next. On the following night, the Home Secretary will let us know the extent of the re-construction he is at length—let us fain hope, in a statesmanlike spirit—willing to give the Profession. Let us then, rejoice in the grateful expectation that the coming week may open a new and happy era in medical government; not omitting, meanwhile, by petition and protest, to second every favourable inclination to equity and good feeling.

"Ut vivat castor, sibi testes amputat ipse:
Tu quoque, siqua nocent, abjice, tutus eris."—Alciat. Emb.

"—— Dabiturque licentia sumpta prudenter."—Horace.

We terminated our last article by observing that tea should never be taken in large quantity shortly before going to bed. The chances are that it will prove troublesome either through the kidneys, or the skin. It is a rule in physiology, that none of the secretions are formed with the same regularity or rapidity during sleep, as during waking hours. Any exception to this is either an indication of disease, or is the offspring of contingent circumstances, which may prove more or less hurtful by their persistence. Thus, in diabetes, the condition of sleep is no impediment to the accelerated action of the kidneys, and the sufferer, if not troubled with *eneuresis*, is compelled to rise once, or oftener, in the course of the night; in certain affections of the stomach, with which the salivary glands sympathise, the mouth is never dry during sleep, but is perpetually watered with saliva, which, if it flow down the throat, will sometimes endanger choking; and the relaxed skin of the bed-ridden, and consumptive, is favourable to nocturnal perspirations, that seldom fail to hasten the poor patient's end. Imagination has, now and then, a share in these things. Lucretius finely pictures an infirmity of childhood:—

> Pueri sæpe, lacum propter, seu dolia curta,
> Somno devincti, credunt se extollere vestem:
> Totius humorem saccatum corporis fundunt.

A baneful habit of later life, often the consequence of morbid imaginings, leading to voluptuous dreams, he represents with no less philosophical than poetical skill:—

> Tum, quibus ætatis freta primitus insinuantur,
> Semen ubi ipsa dies membris matura creavit
> Conveniunt simulacra foris e corpore quoque.
> Nuntia præclari voltus, pulchrique coloris,
> Qui ciet irritans loca turgida semine multo:
> Ut, quasi transactis sœpe omnibus rebus profundant
> Fluminis ingenteis fluctus, vestemque cruentent.

There are certain things which, if taken just prior to bed-time, produce in a healthy subject, and apart from all imagination, a disturbance either of the kidneys, or the skin, quite equal to what we observe in diabetes, or in the last stage of consumption. A common remedy for a cold, is a profuse potation of cold water, the last thing at night—if the body be well covered with bed-clothes, an abundant diaphoresis will follow—if the surface be chilled, then there will be a proportionate diuretic action. Once in a way, such a remedy is all very well, but, if long-continued, it would likely be the forerunner of settled mischief. Tea, if taken under like circumstances, whether hot, or cold, will produce a like effect. But, as we have said, it is the consequence merely of its sedative, or depressing action. Terror, or mental anxiety, will act just the same. The "please, ma'am, may I go out," of the infant-school child, just summoned to say an ill-prepared lesson, is a proof how rapidly the kidneys will respond to the emotions of the mind. The most pitiable, and permanently injurious consequences have followed detention, or corporal punishment, one of which is the common treatment in such cases. Even in adult life, this is not a rare trouble. Napoleon was apt to suffer from it at certain seasons, and the cool, calculating Talleyrand, was in some-wise its victim. Nor in our country, have senators escaped it. It often distressed Pitt, and more than once drove the indomitable Sheridan from the House. We knew a man, a member of one of the leading debating societies of Edinburgh, who, with every qualification, except confidence, for a good speaker, was yet at any time unable to get

out a sentence, from an incontrollable desire of micturition, the moment he rose upon his legs. It mattered not if he had taken no fluid for hours before going to the society; the effect was just as severe. Nothing that he could do relieved him of his misery, and though intended for the bar, he gave up all idea of ever being able to speak in public. We have met with many similar cases, but never with one so utterly intractable. With the exception of the instance just named, we have never known this infirmity not to yield either to common precaution or to some simple remedy. The subject is popular and important enough to deserve that we should give it the results of our personal observation and experience. We lay it down then as a fundamental rule, that men who suffer from this liability, should be especially careful to abstain from diluents for some hours, experience will tell them how many, prior to the occasion of public speaking. It is of the utmost consequence that this rule, too often neglected, be scrupulously observed. Should a diluent or stimulant be in some sort necessary, limit the quantity as much as possible, and let the material be milk, oatmeal and water, or port wine. It is desirable that the fluid swallowed should have some solid matter in it, for this restrains the diuretic property. There is a filtration required, which makes the passage of the liquid part more slow. As they say of the black Bohemian beer,

> Nil splssius illa,
> Dum bibitur, nil clarius est, dum mingitur; unde
> Cons t at, quod multas fœces in corpore linquet.

To explain the matter physiologically, the veins possess the power of absorbing, by their open mouths, pure fluids, whilst the absorbent vessels only take up less rectified materials. In the one case then, the veins spreading over the surface of the stomach will carry an unmixed fluid from this organ, directly into the torrent of the circulation, whilst in the other the absorbed matter having to traverse the more slow and circuitous route of the lacteals, is much longer in becoming the companion of the blood. Now whatever is absorbed by the lacteals, is less foreign, stimulating, or troublesome to the blood, than such other as may be absorbed by the veins, so that there is a reason, both in point of time and of condition, why diluted, more than undiluted matters should stimulate the kidneys to a rapid action. Those who are familiar with debating societies, and are well used to criticise their workings, know how intolerable a thirst will often seize a man who is about to make a speech. Though much used to debate ourselves, we have never been troubled with much nervousness, and have therefore had plenty of opportunities for observing the more timorous and unlucky. We have often ventured to predict a new speaker in the person of a man who has lustily plied the water bottle. And we have known many an aspirant for rhetorical honours cut short by the abominable action of this water upon his sensitive system. To treat this matter physiologically also, a man who sits under any exciting apprehension, say of speaking, becomes fixed to one thought—it possesses him to the exclusion of his common mind, and even makes a fool of his senses. He sees nothing, hears nothing, feels nothing—he is the victim of one single idea—he is in a trance—he is sleeping and dreaming with his eyes open. In thus suddenly locking up his senses, and calling home his thoughts, can it be wondered that his mouth should become dry? Mucous secretion becomes suddenly suppressed and the matter last effused, instead of being carried off by swallowing becomes dried by evaporation, and the mouth and fauces are coated, as it were with varnish. In such a plight as this you may swallow water to all eternity, and it will never quench your thirst. It is such a state of dryness as you feel, when, after a hearty supper, singing, cigars, and so forth, you awake in the night, and finding you have already dicussed the contents of your water-bottle, wonder how you can persist in being so thirsty. What liquid you swallow glides down your throat as it would over a mackintosh. It leaves no trace of itself, and takes nothing away. But it will not spare your kidneys for all that. In bed or in the debating room this "cold water cure" will only add to the complaint for which you took it. *The secret is to eat a little something solid and difficult to chew*—it will restore the action of your salivary glands, clear the mucous membrane of your mouth and throat, and make a wine glass of water do more than, under opposite circumstances, an *amphora* of liquid could do. We have said that the preparatory drink of the public speaker should contain some solid matter—if he will insist upon a more dilute beverage, at any rate it should be taken upon a tolerably full stomach. In proportion to the amount of solid matter it meets with in the digestive organs, will be the slowness with which it distils away. All acids should be avoided—rhenish wines, lemonade, oranges, gin and water, whiskey toddy, and tea. With these precautions, should the infirmity continue, then some remedy may be tried. It is said of a once-celebrated barrister, that his best speeches were made with a blister on his chest: by this we are to suppose, that his vocal and respiratory organs were so weak as to require an artificial stimulus to enable them to perform any extra work. The opposite treatment often does good to men whose kidneys are unusually weak or irritable. We have known the troublesome *liquidity* of unpractised speakers completely relieved by a plaster of opium or belladonna over the loins. Twelve inches by eight is the most convenient size—it may be put on a dozen hours before the period of trial, and taken off immediately afterwards. The same plaster will serve once a week for a year, and as we have said, is a most serviceable remedy. A strong stimulant in a solid form is often of much use, by exciting the stomach and earlier intestinal apparatus; it will divert most happily from the kidneys, at the same time not failing to render the brain, by sympathy, some assistance. A man's mind is as little at his command as his courage, *if his stomach be cold.* "Warm his heart," as he calls it—he speaks of the *actual*, whilst physicians speak of the *physiological fact*—and intelligence and courage will be each within his summons. The commodity is portable enough—a rhizome of ginger, or cayenne lozenges, are all that you want. It is said of a man distinguished at the bar (we forget his name) that he never could speak without a ball of pack-thread in his hand, which he called *the thread of his discourse*—we knew a man who never could make a speech without his piece of ginger, which he called *the stimulus of the occasion*, and capital ginger *it* was, and a capital speaker *he* was, and much was the Edinburgh Hunterian indebted to both of them. Another means of preservation against the unhappy circumstances we have spoken of, is opium. And it is really a good remedy in cases where its influence on the brain does not interfere with a man's intellectual operations. Whenever such is the case, of course it ought to be altogether discarded. But under the best of conditions it is apt to be a treacherous remedy. It will take liberties with your mind when you are not aware of it. It is best used in morphia losenges, which must be sucked sparingly, or mischief will follow, as we shall describe anon.

THE MAN OF VERACITY.

> Ecce iterum Crispinus, et est mihi sæpe vocandus
> Ad partes; monstrum &c. JUVENAL.

We have a devoted love for a "*Gentleman,*" using the word in its *English* sense—a sense giving an idea no other nation knows of. With the ordinary share of humanity's weaknesses and faults, he is never without the two greatest of social virtues—probity and truth. His mind of honour knows of no temptation to sin against these. Wrong, he may be in many things, he is always right in this—that *guiltily* he will injure none but himself. Whatever he aims at, he will have it honestly, in fair fight and above board, or not at all. He is *sans peur et sans reproche*. There is in him a natural dignity of soul that instinctively loathes low courses as a pollution. One deliberate falsehood would stamp him to his own conscience a villain for ever. To him, there is such a thing as self-degradation, and he avoids it as the greatest of miseries and the most guilty of crimes. In every formal untruth he feels that there is the same unprincipledness in question which on other matters constitutes the pick pocket, the swindler, or the other elements of low society, and a sacredness of regard for veracity is the primary quality to him, that draws the broad line of demarcation between the order of gentlemen and the mob of felons and petty larceners. Happy for England that we have the idea of Gentlemen! Happy that we insist so rigorously on its realization! Happy that our senate—the nation's first assembly of gentlemen—by the prefix "*honourable*," brands as ridiculously infamous, and with the hot mark of irony, all entering it, who are *not* gentlemen.

It is our happiness this day to signalize, from our own ranks, a brilliant specimen in public life of what we have so faintly attempted to depict on paper. We have to record a transaction which, combined with others from the same source, proves that our learned body, our time-honoured calling, has won the distinction of giving the House and the country—its noblest exemplar of that noble being—the *English Gentleman.* The man of honour, *par excellence*, the man, *par excellence*, of veracity—the mirror of chivalry is—how proudly we note it—is—who would have thought it?—Mr. WAKLEY!

Several months since, that honourable person was in collision with the Provincial Association for expressing on Medical Reform some moderate opinions which he has himself since adopted. It is said of Huntingdon, the pious preacher, that when shoes wore down i' the heel or galligaskins, immodestly threatened to show the "disparting" effects of time, the physical want became a matter of psychological aspiration, and forthwith a pair of handsomely polished bluchers or well-fitting smalls, made their visible and palpable descent. It is much the same thing of Wakley. He has incontestibly super-ordinary help in his necessities. It was at the period we speak of, a matter of great pecuniary consequence to smite, hip and thigh, the rulers of the Association, and their literary organ. Forthwith, therefore, appeared in the *Lancet*, a dashing epistle from Nottingham, signed "a Member of the Association," and saying and doing, by an odd coincidence, exactly what Mr. Wakley stood in need to have said and done. But now came out the marvel. No Member of the Association wrote the letter; every one of them resid-

ing in or near Nottingham spontaneously joined in disclaiming any knowledge of it till it made its mysterious apparition in the *Lancet*. Hence, as some scoffers charged Huntingdon with buying his heaven-sent breeches at the next tailor's shop, many accused Wakley of manufacturing his member-written letter in his own editorial bureau. Small headed men! They fancied that because it served so well his ends, he would have been the man to stoop to such an ignominious forgery. For ourselves, we, who know him, would much sooner believe that the letter was miraculous, than that he, who profited by it, ceased to be a *man of honour*. Of the two hypotheses, the latter is a myriad-fold more incredible.

"One down, the other come on" is the old rule of English pugilism, and when Mr. Wakley had vanquished the Provincial Association by adopting their opinions—a dangerous ordeal for the poor people—he set to work in good earnest with the National Association. Here, again, a letter was wanted, and here again—wonderful to say—the letter came. A bodiless "Member of the Committee" with a power of creative invention large as that of Huntingdon's ghostly tailor (who made super-substantial small clothes out of viewless broadcloth) detailed against his Committee brethren (in the flesh) imaginary turpitudes of the deepest dye, exactly in the terms Wakley would have dictated, if acting by mesmeric sympathy on the mental organism of the incorporeal scribe. Again comes your miserable earthly disclaimer, as if that—however conclusive on ordinary principles—*could* cause discomfiture to one so far above their ken as Mr. Wakley. With vain preciseness, all the "members of the Committee" declare, that they know nothing of the letter or "its unfounded statements and fabrications," as they impertinently describe its contents; and they go so far as to call on our distinguished representative, the mirror of English gentlemen, to account for his publication of what they almost, in direct terms, name as his own forgery. But what an answer to the audacious men! Mark how meekly "the man of veracity" sits under the charge of "dishonour," yet, how proudly he challenges their right to question *him*, (*him*, above all others!) about the fellow "member" and accuser he had given them. But the world shall lose no iota of this historic document. Every word is pregnant with the high pride of an honourable mind: there is no trace of a juggle in it from beginning to end.

Gentlemen, 33, Bedford-square, April 28, 1845.

A letter, signed by you, and addressed to the Editor of the LANCET, was sent to me last night by Dr. Bennett. You request to be furnished with the name of the author of a communication which was published in the LANCET of last week, relating to the proceedings of the Committee.

Without admitting your right to make such a request, I state at once, unhesitatingly, that the letter in question was sent to the "Lancet-office" without any name being subscribed to it, and, considering the circumstances which have since transpired, I regret exceedingly that it was published.

I have the honour to be, Gentlemen,
Your obedient servant,
(Signed) THOMAS WAKLEY.

To Messrs. Ancell and Bird, Hon. Secs. to the Committee of the National Association of General Practitioners.

It must not be supposed that the letter's unforeseen "*disclaimer*" by the Committee was one of the "transpiring circumstances" which induced the "man of veracity" to "regret exceedingly that it was published," nor should it be forgotten, that when the slanderers of Mr. Wakley's character, which during twenty years has stood fire-proof, the severest ordeals to which that gentleman in his utmost ingenuity could submit it to—it must not be forgotten, we say, when these foul and infamous slanderers choose to accuse the hon. M.P. with dishonour, that if a laxity of assertion exactly proportioned to his needs really formed, as they say, his most prominent characteristic, he would most certainly have denied in his note, at once and unhesitatingly, his knowledge of the *writer* of the mysterious letter. There was very little more danger of detection in that assertion than in the fellow one, that the letter came "nameless," and the additional falsity would have saved the reply from the charge of a shuffling evasion. But, no! Mr. Wakley is emphatically the man of honour—"at once and unhesitatingly" *the man of veracity*! He knew the writer as well as he knew himself, and for worlds he would not disown the honouring acquaintance. What a scrupulous regard for truth!

But one devout word in parting with our Huntingdon of medicine. Two miraculous letters opportunely coming to hand when most wanted is certainly—as the Cornish wreckers say—"a great Providence, yea, a very huge Providence." *They* may be readily believed, but a *third* might be dangerous. It would stagger neophytes like ourselves. There is a limit even to faith, and perhaps Mr. Wakley will use his influence that our weakness be not overtested. We entreat him earnestly to put off his next miraculous letter at least for another twelvemonth, during which severe probation the *Lancet* might adopt as its consolatory motto:—

De par le Roi, defense a Dieu
De faire miracle en ce lieu.

THE ROYAL COLLEGE OF SURGEONS.

Petition of Mr. Guthrie, F.R.S.

The Petition of George James Guthrie, one of the Council and Court of Examiners and late President of the Royal College of Surgeons of London,

Humbly showeth,

That your Petitioner did cause a Petition to be presented to your honourable House in the last Session of Parliament, praying that no Medical Legislation might take place until certain errors in the Charter lately granted to the College of Surgeons should be rectified. Your Petitioner, aware of the unfitness of this Charter for the purposes for which it was intended, opposed its acceptance in his place in the Council of the said College, and has on every possible occasion objected to its continuance. The knowledge your Petitioner has since acquired of the manner in which it has worked, has convinced him of the advantages which would be derived from some material changes being made in it, in which he believes he only concurs in opinion with nearly all the Surgeons of England who are members of the College.

The parts of the Charter to which your Petitioner particularly objects are those which, from their supposed liberality, are considered, by the few advocates it possesses, to form a praiseworthy feature in its construction, but which your Petitioner is ready to prove, are the principal causes of the discontent which has been manifested throughout the Profession, in a manner hitherto unprecedented; and that, so far from any of them being acts of liberality, they are really otherwise, being *either deceptive in their nature, or so despotic and unjust in their character, as to be discreditable even to a purely arbitrary government*, and the retention of which cannot be maintained before any competent Court or Committee of Inquiry. Your Petitioner believes that the members of the College resident in England who have been aggrieved are fully capable of stating their grievances in a manner which forbids all interference on his part; and he should not venture to approach your honourable House, if it were not that he has been called upon by many of those medical officers of the different branches of the public service, who are now serving their Country in far distant lands, to maintain, to the best of his ability, the rights and privileges of which they have been unjustly deprived, and which they cannot by any efforts of their own recover, unless some change be made in the Charter.

Your Petitioner prays your honourable House to remark, that *these gentlemen are deprived of the rights and privileges which have been handed down to them for a hundred years, under a solemn compact, which all parties concerned have sworn to observe, and by an ex post facto law, retrospective in its effects and unjust in its operation.*

Your Petitioner believing that none of the statements which have been made to, or which have been laid on the Table of your honourable House, in support of this Charter, have any real foundation, and that they all admit of complete refutation, prays your honourable House to appoint a Committee to inquire into the various statements and supposed facts which have been adduced on all sides, before any further medical legislation shall take place, in order that the truth may be may be elicited and justice done.

And your Petitioner will ever pray.

G. J. GUTHRIE.

PROCEEDINGS OF THE NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY.

294, REGENT STREET.

This Association is progressing admirably. Notwithstanding the embittered attacks of some industry and great want of principle, there has not been a secession of even six members, while the number of new members, and the amount of contributions in the form of donations, received weekly (from forty to fifty pounds) places the society's prospects in a most flourishing condition. In consequence of the worse than uncourteous rebuff experienced from the Council of the Royal College of Surgeons, the measures that were previously being taken to procure the expected Charter of Incorporation, are now being urged with increased vigour and determination. The Society of Apothecaries' and the Association have coalesced to form a deputation to Sir James Graham, to confer with him respecting its provisions, and the former body, at the express request of the Home Secretary, have, at a meeting of the Court of Assistants, appointed two members, fully empowered to surrender to the Government the Act of 1815 with all its attendant immediate and contingent advantages and privileges, on the condition that the National Association of General Practitioners receives a charter of incorporation, with power to examine its own members, and grant diplomas on proof of efficiency, its members being independent of the other medical and surgical corporations, and its diploma a sufficient title for every medical and surgical appointment throughout the country. The Committee of Association on its part, as we have been informed, have nominated Mr. Pennington its president, and Messrs. Bird and Ancell the secretaries, a deputation to arrange with the Government the various provisions and features of the Charter, and to accept or reject the one proferred by the Government, according as they may deem it most advisable for the interests of the Association generally. The appointment of these gentlemen to form the deputation remains still for confirmation by the Committee, but there is not any doubt but that their nomination will be confirmed. Meanwhile a public meeting of the Association has

been summoned by circular for Tuesday evening next, May the 6th, at the Hanover Square Rooms, at 6, p. m., when these and other important matters will be submitted for the consideration of the members. With a view also to elicit the opinion of the members with respect to the elective franchise, two queries have been submitted to them by circular, the answers to which, which it is expected will be received before the public meeting takes place, will guide the Committee in the arrangements of that part of the new Charter.

That the nature of the queries above alluded to, and the business to be transacted at the public meeting may be fully understood, we subjoin notices of the questions which it is intended to send to all the members of the Association.

"I.—Whether all Members of Council, after the nomination of the first Council, should be elected by the Members of the College whose Diploma or Licence bears date previous to the day of Election,—Five years? Ten years? Unrestricted? Or for what term of years?

"II.—Whether after the Nomination of the first Council, every Member of the College should be eligible to be a Member of the Council whose Diploma or Licence bears date previous the day of Election,—Twenty years? Fifteen years? Ten years? Unrestricted? Or for what term of years?"

The circular accompanying this is as follows:—

"That the Committee may be in possession of the most accurate information possible during the pending negociations, the Members of the Association are called upon individually to declare their opinions upon the subjects of the Franchise, and of the Qualification for Membership of the Council. You will accordingly oblige by placing your signature in the accompanying schedule, against those propositions which you wish to affirm; and returning the schedule under cover to the Committee by the earliest post.

"A Special General Meeting of the Association will take place on Tuesday next, May 6th, at the Hanover Square Rooms:—

"To receive a Report from the Committee, and to confirm their Proceedings, also:—

"To receive a return of the opinions from the Members of the National Association on the subject of the Franchise, and of the Qualifications for the Membership of Council, and to declare the result.

"The chair will be taken at six p.m., precisely, and your attendance is earnestly requested."

It may be added, that Sir James Graham has at length consented to treat with the Committee as the authorized representatives, or to use his own words—"the plenipotentiaries" of the body of General Practitioners, and there can be little doubt that a College of Medicine and Surgery will be immediately established, which, if worked with the zeal and enthusiasm that now animate the Committee, will, in a very few years, force the other two Colleges, into a conjunction in self-defence. The Committee are pledged to take nothing less than an independent incorporation, with the fullest powers in reference to Surgery; and Sir James Graham has shewn fair grounds for the belief, that to avoid a voluntary incorporation (which will be royally recognised on any change of ministry,) he will use the handsome, and generous abdication of the Society of Apothecaries—an act unparalleled in corporate annals—as a happy aid to build up a National Faculty for the Profession.

Votes of confidence in the Committee are coming in with nearly every post.

The Medical Protection Assembly, having doffed their name, which they conceived somewhat odious, and selected a rather respectable channel of communication, Mr. D. O. Edwards, recently applied to the College of Surgeons for an interview, in the hope of inducing the latter to relax somewhat the stringency of their monopoly. The Council, however, peremptorily declined to receive any deputation in anyway contaminated by so unfortunate a connection.

SYDENHAM SOCIETY.

The anniversary meeting of this society, called by means of public advertisement, and not by private circulars, was held at the society's apartments on Thursday evening, the 1st of May, at 8 p.m. Dr. Paris in the chair.

The report of the council read by the secretary, which was exceedingly meagre and scanty, stated that a third volume would soon be ready for distribution among the subscribers of the past year; that other works were in course of preparation, including the complete works of Dr. William Hunter; and, further, that the council had it in contemplation to prepare an extensive and accurate medical bibliography, for the which, however, more ample funds were requisite than could be at the command of a recently instituted society with a fluctuating subscription. With a view, therefore, to the carrying out of this object, a sum had been taken from the balance of subscription, and invested in the names of the president, treasurer, and secretary, in the purchase of £195 8s. 2d. in the three per cent consols. The report further stated that there had been a great increase in the number of subscribers, there being at present 2,070 members. It then proceeded to discuss certain objections which have been raised in various quarters to the manner in which the objects of the society have been carried out, some members requiring the publication of modern works, while others seemed desirous of making it a society of medical antiquarians. The council congratulated themselves, however, that the dissentients out of so large a number of subscribers were so few, and argued thence that their proceedings must have given general satisfaction; and they further stated that it was their duty to cater, not only for the few, but for the many—and that in all their publications their object was to encourage a high standard of literary taste, and to publish such works as would afford sound medical knowledge. They were also of opinion that the demand that existed for the publications of the first year, was an additional proof of the estimation in which their labours were held; and it was stated that these works would be reprinted as soon as five hundred subscribers could be obtained for them, so as to warrant the council in incurring that expense. A donation of ten pounds from Sir Alexander Crichton was also acknowledged.

The financial statement of the treasurer showed a balance in hand from the first year's subscription amounting to £929 8s. 8d.—subscriptions received during the past year, £2,150 15s.—interest from the Union Bank, £21 16s. 1d.—consols' dividend, £2 16s. 11d.—making a total of £3,077 16s. 8d. Of this sum there remained a balance of £914 19s. on the 25th of March last, the expenditure including nearly £40 for petty expenses, upwards of £300 for editorial charges, upwards of £400 for book-binding, £500 for paper, £196 purchase of consols, ect.; £55 16s. had been received since as subscriptions, and additional expenses incurred, including £157 10s. granted by the council to the secretary as a gratuity, and about £425, the estimated expense of the first volume of Simon's work, about to be published by the society. The balance in hand at present is therefore £300 18s, 4d., besides the consols, and about two hundred copies of the published work, still in hand.

Dr. Willis proposed the adoption and printing of the report, and eulogized the council for the publication of the works of Paulus Ægineta, which, he said, in such a society, must have been published sooner or later. The promises that were made respecting the future were, he thought, very gratifying; and he was particularly pleased with the contemplated medical bibliography.

The proposal was then duly seconded and carried, as were also votes of thanks to the respective officers of the society; after which the scrutineers reported that the following house-list, nominating the officers and members of the council for the ensuing year, had been unanimously adopted.* The meeting was thinly attended.

President: Dr. Paris, F.R.S.; Vice-presidents: Sir Alexander Crichton, M.D.; Dr. Alison; Dr. Hastings; Sir Benjamin C. Brodie, Bart.; Sir William Burnett, M.D., F.R.S. K.C.H.; Dr. Davidson; Dr. Chambers, F.R.S. K.C.H.; Sir James Clark, Bart, M.D. F.R.S.; Sir Philip Crampton, Bart. F.R.S.; Sir Henry Marsh, Bart. M.D.; Sir James M'Grigor, Bart. M.D. F.R.S.L. and E.D.; Dr. Haviland; Mr. Hodgson, F.R.S.; Dr. Holland, F.R.S.; Dr. Kidd, F.R.S.; Mr. Travers, F.R.S.; Council, Dr. Arnott; Mr. Ancell; Dr. Clendinning, F.R.S.; Dr. Copland, F.R.S.; Mr. Erichsen; Dr. Forbes, F.R.S.; Dr. A. Farre, F.R.S.; Mr. Hilton, F.R.S.; Dr. Hodgkin, F.R.S.; Mr. Lane; Mr. Luke; Mr. Martin; Sir George Lefevre, M.D.; Mr. Drewry Ottley; Dr. Pereira, F.R.S.; Mr. Phillips, F.R.S.; Dr. Forbes Royle, F.R.S.; Dr. Sharpey, F.R.S.; Mr. Henry Smith; Mr. Solly, F.R.S.; Mr. Squibb; Dr. Th. Thompson; Dr. Wilson; Mr. E. Wilson, F.R.S.

* This is decidedly an erroneous statement: to our knowledge several of the balloting papers were amended by the striking out obnoxious names from the list of vice-presidents.

MR. DERMOTT ON MEDICAL MOVEMENTS.

(To the Editor of the Medical Times.)

SIR.—Upon my calling, with some medical friends, on an M.P., this last week, we were not a little surprised to hear him unreservedly assuring us, that *Mr. Wakley had been soliciting his support in favour of Sir James Graham's Medical Bill!!!*

I must leave the profession to draw what conclusions they please from this fact, deeply lamenting that they have so long rested their hopes upon so rotten a foundation as the aid of this *soi-disant* friend of the profession.

Pray compare this droll canvassing with the worthy M.P's. Leader of Nov. 16th., wherein he designates the Council of Health as the "*Monster*," and Sir Jas. Graham as the head and front of its offending, by his monopolizing all its power and influence, and the Bill as "one exciting the strongest feelings of indignation and disgust—as an odious and detestable project"—also of Nov. 23d. and 30th., with succeeding Lancets. Dec. 28th., he says: "Of the twenty-two clauses of the Government Bill, which we have already examined in this journal, not one has been so framed as to deserve the support of the profession or the public, and all the guiding principles and leading provisions of the measure have proved to be precisely of that character and description, which were calculated to arouse against them the bitter hostility of nearly the whole of the legally qualified practitioners of this kingdom. In concluding our analysis of the clauses of this *ruinous* Bill, truly can it be declared, that we have completed one of the most odious and painful duties we have had to discharge since the first publication of this Journal."

The duplicity to which I am now referring, is too palpable to last long; but, alas! medical men are only now thoroughly finding out their error when it is too late to correct evils resulting from it—when the Bill is on the eve of passing—when the insulting, degrading, and ruinous charter is about to be established upon a secure foundation, and medical monopoly is becoming a castellated tower of strength.

The sycophantish conduct of Wakley towards Sir James Graham is disgusting. Does he think to hood-wink the profession against the monstrous evils of the Bill, by descanting upon the gentlemanly strain of his speech? A speech, after all, consists but of words, whilst the Bill is to become an Act of Parliament. Throwing aside, moreover, the verbal garnish of this speech, we find him distinctly stating, that he still adheres to the principles upon which he introduced his first Bill; that is to say—the non-representation of the profession—the representation of the self-elect cliques of our medical corporations, and free trade in quackery. The Bill in every repulsive feature is the same.

Sir James Graham may be as well-meaning towards the Medical Profession as any other honourable member in the House. He may be "most anxious to sustain the honour, and the

attainments of medical practitioners," but he has a strange way of shewing it. As a proof that he must be very ignorant of the real state of the profession, he coolly stated in the House on the 7th, that he was at a loss to understand what were the grievances or exclusion to which Col. Wood referred, viz., the grievances of the members of the College ! ! ! It requires no spirit of divination, after this, to see that Sir James Graham has not much troubled himself with reading the petitions that have been sent up against the Charter, and that Mr. Wakley, with all his interviews, has failed to give him a proper "*course of private instruction.*"

But a short time ago, the Committee of the National Medical Association were, with Mr. Wakley, everything that was good and noble—a week or two afterwards they were a "Lawless Set," everything that was infamous—because they would not admit him and his "Man Friday" Lynch into their committee—because they would not subject themselve to "Crowners' quest," or Lynch-law.

Let the truth, for the sake of public good, be plainly told. The National Association have hitherto acted wisely for their own reputation, and honestly towards the public; the fact is, they find it more prudent to close the doors of the committee-room against fresh accessions of number, than to admit Mr. Wakley and his clique, and incur the risk of his doing to them what he did to the former Association rather better than a year ago*—namely, convert it into a species of inquisition on a small scale, a cabal for abusive declamation and personal persecution, expelling those who would not servilely succumb to him, or compelling them to resign, closing the committee-room doors, making the said committee *in reality* as close a "hole and corner" *Lancet* job as it could possibly be, all our practical plans for active operation being completely broken up like the Association itself.

Verily, Mr. Wakley's expelling, persecuting hole and corner clique will hereafter have enough to answer for, before the tribunal of public opinion. It is known to all the profession, that the Association above alluded to, having been re-christened by Mr. Wakley "The Medical Protection Association," having had sown in it the seeds of its own dissolution, witnessed its own demise a few weeks ago.

May I be permitted to ask,—How came it that on Friday night last, the Bill was moved to be read a second time, without opposition? How came it that Mr. Wakley, who, a few weeks ago, insisted that the "*Monster*" should not be read without determined opposition—who would die on the floor of the House of Commons in opposing its leading principles—that he who has called upon the profession to oppose it in every stage, and by every means—who has so broadly objected to almost every one of its clauses, as well as to its general principle—how came it, I ask, that on Friday night, he "would not offer any objection to the motion, that it be read a second time," that he moreover stated what was absolutely incorrect, viz., that "the discussion of the principle of the Bill should not take place on the second reading, but on its committal." No such thing, I maintain, was stated, but that it would be opposed. How came it that on the same night, as soon as the order of the day for the second reading of the Bill was read, he both presented, and supported a Petition (from some of the University Students,) in favour of the Bill, "the petition expressing satisfaction at the Bill, but objecting to two or three features," whilst he shirks off the discussion of the principle of the Bill until its committal. I always thought that when members really object to a bill, the opposition is on its second reading—at the very moment when, behold, he presents a petition in support of it.

The next stage of the Bill is, also, put off until Wednesday, the 7th of May, the night before the Whitsun-holidays, when very few (perhaps *packed*) members will be present to secure its passing. This really appears like an intention on the part of the chief managers of the Bill to smuggle it through the House, or a repetition of the Bill-juggling farce of 1840. (See *Medical Times* March 1844 page 459.) Mr. Wakley also on Thursday last, the night preceding the second reading of the Bill, postpones his motion for a Committee of Enquiry into the operation of the Charter of the College of Surgeons until next Tuesday fortnight; not that I think the profession would get any good by the inquiry, if the evidence were picked and packed (that of the accused parties) as was the evidence before the Committee of 1834. The accused College Council will of course give a good account of their own character and conduct; whoever heard of bad people giving themselves bad characters? The more I think of it, the more I distinctly see that the attack against the Bill should have been made on the second reading. Wakley, in not doing so has secured the passing of the Bill through the House of Commons.

Mr. Wakley seems determined to contribute to his own undoing as a public character as much as possible. The following act of this Aristides of the profession will form a climax:—A week or two ago I sent my advertisement of the publication of my "Objections against Sir J. Graham's Medical Bill," when the young man behind Churchill's counter immediately returned it to the gentleman who presented it, with the observation, that it could not be inserted. Well, supposing that the refusal only applied to political topics, I sent this week an advertisement of the Summer Courses of Instruction about to be delivered at the Charlotte-street School of Medicine, the identical one which now appears on the cover of the *Medical Times*; this was also refused, and upon the medical gentleman who took it asking the reason, the response was, that Mr. Wakley had given them orders not to insert in the *Lancet* any advertisement of Mr. Dermott's.

Mr. Wakley could not have hit upon a device more injurious to himself, and more complimentary to me; he will, by this means, teach the profession one great practical lesson, viz., that medical men, lecturers and all, can well do without advertising in the Lancet, and several will, no doubt, ere long, take avail of this most useful demonstration. So much for the high-mindedness of the Pseudo-medical Senator. Does he not know that when a man obtrudes himself upon the public as their servant, his public actions are as a point of justice open to the scrutiny of all individuals with whose interests he has implicated himself. He has completely thrown overboard his principles as a reformer, he has violated his duty towards the public as a Journalist, and the ordinary usages of society, in a manner most unprecedented.

Your obedient servant.

G. D. DERMOTT.

Charlotte Street School of Medicine, Bloomsbury, April 28th., 1844.

* See *Medical Times*, of March, 1844.

HOUSE OF COMMONS.—FRIDAY.

PHYSIC AND SURGERY BILL.

Sir J. Graham moved that the order of the day for the second reading of the Physic and Surgery Bill be read.

Mr. Wakley said he had to present a petition, signed by nearly 200 students of University College, London, expressing their general satisfaction at the introduction of this bill, and stating their objections to two or three features of the measure. The petition would have been more more numerously signed, had not many of the students been absent from town.

Sir. J. Graham then moved that the Bill be read a second time.

Mr. Wakley said, it was understood on a former occasion that the discussion on the principle of the Bill should not take place on the second reading, but on the committal. He would not, therefore, now go into the question; but he wished to observe that he had seen it stated in print that the right hon. baronet, the Secretary for the Home Department, considered it to be impossible to enfranchise in the General Medical College of London the great body of the General Practitioners. He wished to know from the right hon. baronet whether or no the door was closed between the Council of that College and the General Practitioner.

Sir James Graham said, he was obliged to the hon. gentleman for not insisting on his right with respect to the second reading of the Bill. He thought, upon the whole, the day which had been fixed by his notice would prove the most generally convenient. The day on which he proposed to proceed with it, would be the last day before the Whitsuntide holydays, namely, Wednesday, the 7th of next month. He had fixed that day, because he hoped to perfect some arrangements which would enable him to alter the Bill in some respects; and he could assure the hon. gentleman that, in a measure of this kind, which went so seriously to affect the interests of so large and important a class, the most indulgent consideration would be given to their feelings and the circumstances in which they stood. But at the same time it was not to be forgotten that there were other important interests to be affected by the measure. With respect to the length of time that students might be engaged in preparing themselves for the medical profession, he should merely say at present that he did not feel indisposed to make every reasonable allowance for the position in which they were placed; but with regard to the standard of qualification, that was an entirely different matter, and one with regard to which he felt no small difficulty. Under the proposed regulations the test for General Practitioners would be examination; and he conceived that that would be as much for the interest of the community as for that of the profession itself. Having said so much, he wished to add that he reserved to himself the power of considering in what other manner he might be able to promote the interests both of the community and of the profession, by means of the regulations which this Bill would be made to contain. The interest of all parties, he assured the hon. gentleman, should be fully and fairly considered. Then, as to the question which the hon. gentleman had addressed to him, asking, was the door closed against all negotiation between the Council of the College and the great body of General Practitioners, he need only remind the House that they all possessed an opportunity of seeing the correspondence that had taken place on the subject. Before that correspondence had passed between the parties to it, he did entertain hopes of a satisfactory adjustment. Since that time every other gentleman in that House possessed as sufficient means as he enjoyed of forming an opinion for themselves. He was not prepared to say that the door of negotiation was wholly closed; but he confessed that his fears exceeded the hopes which he entertained of any adjustment. He was not sanguine, at the same time that he did not despair, that some arrangement satisfactory to the great body of general practitioners would be eventually effected.

Mr. Hume thought that equality of qualification throughout the United Kingdom, should, if possible, be accomplished; and with that view, that an independent body should select examiners from England, Scotland, and Ireland.

Mr. Wakley said the gentlemen whose petition he had presented feared nothing from any test that might be imposed on them; and he moved for the answer of the Council of the College of Surgeons, to the letter of the General Association of the General Practitioners.

The Bill was then read a second time, after which

Sir J. Graham said that, as a member of the Government he had no objection to the production of the paper for which the hon. gentleman moved, but as a member of that House he did not like to join in making an order which they had no authority to enforce.

Mr. Warburton said, that a committee might be moved for; that correspondence might be brought under their consideration, and it would then become a Parliamentary paper.

Mr. Hume wished to know who gave the Council the power which they possessed? Surely it was from the Legislature; and if so, the House of Commons had a right to be made acquainted with the nature of their proceedings.

Sir J. Graham said, he did not believe there

existed the least objection on the part of the Council to the production of the correspondence.

Mr. Warburton said, that the case of the correspondence in question was precisely analogous to the case of the correspondence of the Royal Academy.

The Chancellor of the Exchequer said that, after what had now occurred, he should be very careful how he wrote letters to any corporation, as even the most private communications might be called for under this precedent.

Sir R. H. Inglis thought it would be far better not to exercise a power of this kind, except in cases of great emergency.

Sir J. Graham suggested that the hon. gentleman might, if he pleased, renew his notice on some future occasion, and in the meanwhile, he, (Sir J. Graham,) would probably be able to produce the papers by command.

GOSSIP AND NEWS OF THE WEEK.

Medical Prize.—The Thurston prize for a medical essay has just been awarded to Charles John Hare, L.M. of Caius College.

St. George's Hospital.—The following prizes for the session 1844-45 were distributed to the students of this hospital on Monday last. Dr. Chambers occupied the chair :—Clinical Medicine. Prize, Mr. William Wadham ; second prize, Mr. T. H. Smith. Clinical Surgery.—Prize, Mr. W. J. Anderson ; honorary certificate, Mr. C. H. Maltott. Practice of Physic.—Prize, Mr. T. H. Smith ; honorary certificate, Mr. J. B. S. Brown. Surgery.—Prize, Mr. Frank E. Barton ; honorary certificate, Mr. T. F. I. Anson and Mr. J. A. Woolfryes. Materia Medica.—Prize, Mr. W. P. Roberts ; honorary certificate, Mr. L. Parnell and Mr. Marley. Anatomy.—Senior prize, Mr. Henry Gray ; honorary certificate, Mr. James George ; junior prize, Mr. James Holloway ; honorary certificate, Mr. William Fuller. Clinical Midwifery.—Prizes, Mr. W. J. Anderson and Mr. James Budd ; honorary certificate, Mr. E. B. Batten. Botany.—Prize, Mr. Henry Gray ; honorary certificate, Mr. William A. Gillow.

The indiscretion of Mr. Wakley's friends has exposed him to some unfortunate indignities during the last week. The number of gentlemen who have been formally addressed by letter to become stewards of a contemplated dinner to the hon. member, and who have peremptorily declined is, beyond belief, numerous. In the small circle of one of our acquaintances more than a dozen applications were made, and as many refusals sent.

Protests against the Council's proceedings are being signed by the English surgeons of each district. We have this week received two : one from Leeds, signed by forty surgeons—the other from the surgeons of Birkenhead and its vicinity. Copies should, in every case be forwarded to Sir James Graham, and petitions founded on them be sent to the House.

Obituary.—We regret to announce the death of Dr. P. Harnett, colonial surgeon at Sydney, New South Wales, aged 38.—Also of Dr. James Mac Donnell, in Donegal place, Belfast, aged 82.

Dr. Jacob, the physician of Dublin, who, in addition to the specialty (well fulfilled it must be owned) of oculist, prides himself with something like Irish consistency on being a "*pure* surgeon," has recently written an address to the surgeons of Ireland, assuring them that the apothecaries or general practitioners are rising gradually into physicians and surgeons, and expresses no little alarm at the prospect of their being registered as licentiates of medicine and surgery.—The engineer is here hoisted by his own petard. The Bill as at first promoted by Dr. Jacob, omitted all recognition of the Irish Apothecaries ; it is now to be altered, and a full amount of justice done to them. Dr. Jacob first reminds us how much he did to prevent the Apothecaries' Society from giving the candidates for their license a good education (!) how he prevented the recognition of the Society's certificates by the College of Surgeons ; and that, failing, on his becoming president of the Surgical College, that the society progressed positively in despite of his opposition, "he considered he was called on to avail himself of whatever additional influence he possessed from his official character to resist the attack made on the body to which he belonged. With this view he delivered an introductory lecture ! The introductory, however, failed, and Dr. Jacob now complains that he is in the jaws of ruin by an organized combination against him—not only of physicians and apothecaries, but also of—surgeons. The fact appears to be, then, that Dr. Jacob—the physician, oculist, and *pure* surgeon—has been making a Quixotic fight, useless to himself and thankless to every body else. The English Jacob —Sir B. Brodie—will by-and-bye perhaps have the same tale to tell.

King's College.—Distribution of medical prizes.—The annual distribution of prizes to the best proficients in the medical departments at this institution, took place on Saturday. Division No. 1.—*Medicine, Surgery, and Midwifery.*—1st prize, James Mason ; 2d, T. S. Bourne. Certificates of Honour.—W. F. Noott, T. T. Dyer, H. Smith. Division No. 2.—*Physiology, and Materia Medica.*—1st prize, W. Brinton ; 2d, S. J. A. Salter ; 3d, A. J. Woodhouse ; 4th, P. Eade. Certificates of Honour.—J. Reid, C. Thompson, W. Fincham, G. Smith, W. B. Gill. Division No. 3.—*Anatomy and Chemistry*—1st prize, J. Reid ; 2d, T. W. Nunn ; 3d, J. J. Arlidge ; 4th, S. S. Salter. Certificates of Honour.—T. Bridgewater, T. J. Strutt, J. W. Elliott, W. R. Crotch, B. Cade. *Botany.*—R. Bentley. Certificates of Honour.—J. J. Arlidge, A. Henry. *Forensic Medicine.*—James Duncan. Certificates of Honour.—J. S. Lavies, W. F. Noott. *Warneford Prizes.*—1st, W. Brinton ; 2d, A. J. Woodhouse. *Leathe's Prizes.*—1st, J. T. Arlidge ; 2d, Robert Tweed. *Associates.*—J. Duncan, J. Ody, J. O. Rayner, S. Soden, R. Frere. The medical scholarship of £40 per annum was gained by Mr. W. F. Noott.

An Elderly Physician who attributes Insanity to an excess of carbon in the blood, has inserted the following singular account in the Times :—*Carbon of the Blood.*—An elderly physician, who has had great experience in cases of insanity, stated to Sir Peter Laurie that having for the last 20 years made the subject of carbon as an agent in the operations of disease the object of careful investigation, he had made some observations which he thought particularly applicable to insanity, and requested Sir Peter would give him leave to see the patients in Bethlem Hospital ; Sir Peter very kindly replied, if the applicant would be at the Hospital the next day (Friday, 18th inst.) he should be there, and would introduce him to the medical officers of that establishment, which was just what the doctor wanted—he had no idea of obtruding himself on the committee ; he did attend, and after waiting for some time was unexpectedly called to come before the committee, to whom, in the presence of the medical officers then in attendance, he explained the action of carbon in reference to insanity, and mentioned the curious fact that there were many cases of insanity in which he could tell merely from looking at the back of the hand, not only that the patient was insane, but that to a moral certainty the case was incurable, and stated at the same time the principle on which this opinion was grounded. The gentlemen of the committee listened with polite attention to his remarks, and Sir Peter put some shrewd questions to him on the subject ; when after some deliberation, during which the doctor was requested to withdraw, he was told, on being called in again, that he might go round the house, but that he must not look at the patients' hands. However, it so happened that he had been at Bethlem two days before by appointment of Sir Alexander Morison, and saw a few of the cases alluded to, which he immediately pronounced incurable without asking them a single question, when the apothecary acknowledged they were deemed so, and were in the incurable ward. These facts are mentioned in hope that some one, who has more time and talent than himself, may be induced to take up the subject of carbon, and make it, what he is pursuaded it may and predicts will be, the foundation of a new system of pathology far more simple, intelligible and beneficial, than any that have hitherto preceded it.

A SELECT PRACTICAL FORMULARY.

TRANSLATED FROM THE FRENCH OF M. FOY, PRINCIPAL PHARMACIEN OF THE HOSPITAL SAINT LOUIS, AT PARIS.

(Continued from page 78.)

Serpentary, Virginian—Powder : ten to thirty grains in bolus or pills ; infusion, one to three drachms to a pint of water ; tincture, half a drachm to two drachms in potion, julep, or mixture. The serpentary of Virginia is very little employed at present, notwithstanding its well-marked stimulant properties, and its action on the cutaneous transpiration. Formerly much vaunted in the treatment of typhoid fever, it is now rarely employed except in the treatment of obstinate intermittent fever, gangrenous affections, chlorosis, &c. ; and even then it is generally combined in equal parts with bitters, bark, or camphor.

Serum, Aluminous (Marc) : two drachms of alum, dissolved in a pint of clarified and filtered whey. Mode of exhibition—by small cupsful in the course of the day in cases of passive hæmorrhage.

Simorouba : it possesses the same properties, and is given in the same doses as the quassia amara.

Sinapism, Ordinary : a sufficient quantity of fresh flour of mustard, deprived of its fixed oil by expression, mixed with a sufficient quantity of warm water.

Sinapism, Ordinary—(very active) : eight ounces of synapism, prepared in the preceding manner, incorporated with from two to four drachms of garlic, and powdered pepper, and from twenty to thirty drops of liquid ammonia.

——— (Much milder), one pound of roasted barley flour, four ounces of strong vinegar, six ounces of white of eggs, mixed together secundem artem, spread upon linen, and dusted with two ounces of powdered black pepper. Sinapisms are applied either naked, or between two pieces of linen, to the soles of the feet, the ancles, calves, thighs, &c. The time during which these topical applications should remain on the parts, varies from two to four hours, but it is not always so long a time before their effect, (rubefaction) is produced. Half an hour to an hour is sometimes sufficient. It is advisable to watch the mode of action of these remedies, in order that their application be not too prolonged. Finally, it is not always necessary to wait until the parts become red, for it sometimes happens that that effect is not produced, until some time after the sinapism has been removed. Sinapisms possess stimulant and revulsive properties, which are usefully employed in a great many cases, such as pleurodynia, rheumatism, gout, &c.

Syrup of the Acetate of Morphia (Magendie) : a simple syrup, containing a grain of the acetate of morphia in every four ounces. Mode of exhibition—half an ounce to an ounce in a draught, as a sedative, and succedaneum of syrup of diacodium.

Syrup of Hydrocyanic or Prussic Acid : see cyanic syrup.

Syrup, Alcaline : see syrup of the sub carbonate of potash.

Syrup, Alcoholic, of the Iodated Ioduret of Potassium (Puche) : four drachms of the iodated tincture of the ioduret of potassium, four drachms of mint water, one pint of simple syrup. Mode of application—four drachms to an ounce in syphilitic and scrophulous affections.

———, with the Proto-Ioduret of Iron (Ricord) a simple sudorific syrup, containing a drachm of the protoioduret of iron in every pint. Mode of exhibition—antisyphilitic, in the dose of from two to six spoonsful daily, in an appropriate menstruum.

———, Aloetic (Guillemin) : a syrup containing thirty grains of the aqueous extract of aloes to the pint of syrup. Mode of exhibition—half an ounce to an ounce as a purgative

——— of Almonds : a syrup prepared with sweet and bitter almonds, sugar, common water, and orange water Mode of exhibition—one to three ounces to a pint of water, to make a cooling drink, which is sometimes taken on account of its pleasant taste, at others, used medicinally in acute affections of the genito-urinary apparatus.

——— of Bellet, Reformed (Bouillon Lagrange) : a drachm and a half of pure nitrate of mercury, prepared cold, dissolved in two drachms of water, and a pound of cold simple syrup, and half a drachm of nitric ether added. Mode of exhibition—a spoonful in the morning in a glassful of water or ptisan.

——— of Catechu (German Hospital) : simple syrup containing two drachms of pure catechu to the pound. Mode of exhibition—half an ounce to an ounce in a little water, as stomachic.

——— of Coffee (Ferrari) : simple syrup containing the extractive matter of an ounce of roasted coffee to the pound. Dose—four to twelve drachms and more.

——— Sedative (Ricord) : four ounces of syrup of poppies, fourteen ounces of syrup of orgeat, mixed together, and (according to circumstances) two drachms of nitrate of potash added. Mode of exhibition—four to six spoonsful daily, in linseed tea, or dandelion, or barley-water, or better still, in plain water, in cases of acute blenorrhagia.

——— of Cascarilla : simple syrup containing the soluble principle of an ounce of cascarilla bark in a pound of syrup.

——— Chalybeate (Willis) : one drachm of sulphate of iron, dissolved, in two drachms of boiling water filtered, and mixed with a pound of syrup of gum. Mode of exhibition—one to two ounces daily, as a tonic and astringent, in chlorosis, leucorrhea, &c.

——— of Cinchonine (Magendie) : simple syrup containing three grains of the sulphate of cinchonine to the ounce. Mode of exhibition—one or two teaspoonsful daily as tonic and febrifuge.

Syrup of the Acid Citrate of Quinine (Magendie) : a tonic and antiseptic preparation containing one grain of the acid citrate of quinine to the ounce of simple syrup. Mode of exhibition—one or two teaspoonsful in the course of the day.

——— of Citrate of Iron (Trousseau) : simple syrup containing from four to six grains of the citrate of iron in the ounce in it, possesses the usual properties of ferruginous medicines.

REPORTS ON DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Inflammation of the Os and Cervix Uteri.

J. C., æt. 26, married, no children.

February 2, 1836.—Complains of severe pain in the back and loins, considerably increased by the approach of a menstrual period; albuminous leucorrhœa. Has been subject to a yellow discharge from the vagina for the last nine months; for the last fortnight she has noticed lancinating pains in the centre of the pelvis; they last only for a few minutes, and come on chiefly towards evening. The first appearance of these pains was just before a menstrual period. Bowels somewhat confined; appetite bad.

Vaginal Examination.—Vagina natural; cervix uteri long, hard, throbbing, and intensely painful to the touch.

Hirudines iv. ori uteri. Confectio sennæ om. mane. Lotio plumbi. ℞. Acidi nitrici dil.; tinct. hyoscyami a.a. M xv. ter die ex infuso gentianæ co. ℥iss.

February 9.—Much better in health; discharge much less and thinner—has had no lancinating pains until the evening of the 7th.; expects the catamenia this week.

Mist. potassæ citratis effervescentis ter die.

℞. Tinct. opii, liq plumbi diacet. a.a. ʒii. Aquæ destillatæ ℥viiss. M. ft. Lotio.

Feb. 16.—Had severe pain of the back, &c., attended with lancinating pains before the catamenia appeared. Her health is better, and the leucorrhœal discharge less; but the lancinating pains continue. Rep. med.

Hirudines iv. ori uteri.

Feb. 23.—Was much relieved by the leeches; has had no lancinating pains since. The discharge is less, and more like that of simple leucorrhœa in appearance. Bowels not open; tongue glossy. Has still a good deal of uneasiness about the pelvis.

℞. Ammoniæ carb. ʒi. Succi limonum q. s. ad saturandum; sp ammoniæ arom. M xv. aquæ. menthæ pip., ℥iss. M. ft. haust. bis die sumendus. Rep. confectio sennæ, et hirudines iv. ori uteri.

March 1.—Leeches bled profusely; feels weak; has had no darting pains, and very little discharge, which is thin, and not albuminous.

Rep. Mistura. ℞. Ferri sulph. gr x. aquæ distill. ʒi. M. ft. injectio.

℞. Pil. ferri co. gr. v. o. n. ℞. Magnes. carb. gr. xv. magnes. sulph. ℥ss. aquæ menth. pip. ℥ss. o. m.

15th. What little discharge there is, is that of simple leucorrhœa; no darting pains; little appetite. Catamenia appeared last week, and without pain. Rep. pil. mist. et lotio. ℞. Haust sennæ primo mane.

22nd.—Has had some pain of back, but it does not seem to be lancinating: is weak, and the stomach appears to be deranged from the steel medicines. There is very slight vaginal discharge, and what there is, is simple leucorrhœa. Omit. pil. ferri.

℞. Acidi nitrici m.xv. bis die in infus. gentianæ co.

℞. Pil. hydrarg. ext hyoscyami aa. gr.v. alternis noctibus; rep. mist. sennæ.

29th.—Is gradually improving. Rep. medicam.

April 12.—Has had no darting pain since. Has had pain of back, which seems connected with constipation.

Rep. omnia.

19th.—No lancinating pain, but has had much dragging and bearing down in the pelvis; slight leucorrhœa. Tongue good, pulse full, but compressible. Rep. mist.

℞. Extr. hyoscyami, ext. coloc. co. aa. gr. v. o. n.

℞. Ferri sulph. gr. v., aquæ distillatæ solve. ℥j. ft. injectio.

26th.—The lotio ferri sulph. does not seem to have agreed with her. Rep. lotio plumbi. Rep. med.

May 17.—Complains of debility, with leucorrhœa. Says she has had no lancinating pains for two months. Rep. med.

℞. Pil. ferri comp., gr. v. o. m.

June 7.—Has had no lancinating pains; discharge simply leucorrhœal; contin. omnia.

The history of this case illustrates the introductory remarks which I made in commencing the consideration of this subject. A puriform discharge of long standing, which probably had its source in the uterus itself; an increase of uterine congestion, with lancinating pains, just before a catamenial period, followed by the albuminous discharge which characterises an inflamed state of the cervix, are the more prominent features.

It was necessary in this case to order repeated applications of leeches, and at the same time to give gentle tonic medicines, soothing the part with tepid saturnine injections, and keeping the bowels open by the mildest laxatives. Under this plan of treatment the health rapidly improved; the discharge began to lose its albuminous character, and the darting pains ceased almost entirely.

Each application of the leeches was attended with marked relief to the local inflammatory symptoms; and a state of intestinal irritation, which I have not sufficiently noticed in my report of the case, was relieved by the citrate of ammonia draught which I have already recommended on a former occasion.

Having kept up this plan of local depletion for a month, and finding that the darting pains had ceased—that there was but a very trifling degree of leucorrhœa, which seemed chiefly to depend on general debility—I ventured to order her steel, both generally and locally, hoping by means of the injection to increase the tone of the vagina and cervix uteri, and to produce a healthy degree of contraction, now that the engorged vessels had been so freely emptied of their contents. To prevent any chance of this treatment disagreeing with her, and exciting the circulation either locally or generally, I no longer trusted to the confectio sennæ as an aperient, but ordered a more active form—viz., some sulphate and carbonate of magnesia; and, not content even with this, I substituted a senna draught for it the following week. The health improved; but in the course of three weeks, as the stomach was somewhat deranged, I stopped the steel pills, and gave her some blue pill every other night, with gentian and nitric acid during the day. In the course of a month I diminished the strength of the steel lotion, and shortly after discontinued it altogether for lotio plumbi, as latterly it had not seemed to agree with her. After a while she again returned to the use of the steel pills, and continued to improve in health and strength until she ceased to attend.

The nature of these lancinating pains is not yet sufficiently understood. That they form a very prominent feature in the early stage of cancer, viz., scirrhus, is well known; that inflammation of the cervix frequently terminates in scirrhus, is also a well ascertained fact; but at present we are unable to say what is the condition on which they more immediately depend. I think it may be safely asserted that they do not depend on incipient alteration of structure, since they are frequently seen in cases—like the one just quoted—where, by appropriate treatment, they will, after a time, entirely disappear, being apparently dependant on local engorgement, connected with derangement of the assimilating functions. Thus, as I have elsewhere remarked:—"It seems more than probable that in these affections they partake of a neuralgic character, and are called into action by the sudden paroxysms of congestion, which take place in a gouty condition of the part: in this respect, they bear a close analogy to the twinge of a gouty foot, and the darts of excruciating pain in tic douloureux depending on gouty or dyspeptic irritation."*

The following case might, perhaps, have been brought under the head of dysmenorrhœa, or ovarian irritation, as both these conditions form prominent features of its early history; but as the symptoms afterwards assumed the characters of inflammation of the os and cervix uteri, attended with considerable derangement of the assimilating functions, I think that it may be introduced here with greater propriety.

Mrs. C. F., æt. 25. Married three years. No family. Tall and slender.

Aug. 22, 1839.—Complains of much burning and pricking pain at the crest of the left ilium, extending to the left groin, increased at the menstrual periods, with numbness, occasionally, of the left hip; has irritability of the bladder, and frequent calls to pass water.

The catamenial periods are preceded and attended by severe pain in the back, and followed by a large discharge of coagula, from some of which the colouring matter seems half drained. The bowels are regular, but there is much gastric derangement.

Has not been in good health since her marriage; had had much anxiety; once thought herself pregnant from a large discharge of coagula having come on suddenly, and not at the catamenial period. Shortly after her marriage her husband fell ill; she nursed him with great anxiety, and seems to have caught cold during a menstrual period, from which she dates the above symptoms of dysmenorrhœa and indistinct oophoritis.

Has been under the care of Dr. H. of W. some time ago for affection of the liver, and more

* On Dysmenorrhœa, &c., p. 49.

recently, of Mr. H., of B., for the pain in the groin, for which she was leeched.

On examination of the part externally, I could feel no fulness, hardness, nor swelling, nor was it tender to the touch; she has pain on assuming the upright posture, but it is not severe. Has leucorrhœa, and slight bearing down. States that she is much affected by taking mercury.

She returned to her home in the country, and was considerably relieved by this plan of treatment. I heard no more of her until

August 20, 1840, when she again called upon me. She states that she has had either a white creamy, or transparent albuminous discharge since March, for which she used astringents, and has suffered from lancinating pains ever since; complains of pain on sitting down upon a hard seat, and during the passage of a costive evacuation. Has much gastric derangement, and frequent vomiting of her food, which returns intensely acid. Complains of rheumatic pains of head and limbs; urine turbid, with a red sediment; has been suffering from piles; much bearing down pain; bowels open.

Vaginal Examination.—Vagina small; os uteri low down and forwards, hard and painful; uterus light and moveable.

R. Bismuthi trisnitr. extr. lupuli, aa. gr. v. o.n.

Rep. mist. gentianæ c. acido nitrico dil.

R. Decoct. papav. c. lotiône plumbi, pro lotione.

Hirudines iv. ori uteri.

25.—Leeches bled well, and gave complete relief, removing the darting pains and sense of fulness and painful weight in and about the pelvis, of which she had hitherto complained. Feeling so well, she has been imprudently walking about, and exciting herself with seeing London sights, the consequence of which is that she has had a return of severe darting pain now and then. Urine clear; gastric derangement greatly diminished; bowels inclined to be purged; leucorrhœal discharge less.

R. Hydr. c. creta, Pulv. Ipecac. co. a.a. gr. v.; M. ft. Pil. ij. hâc nocte sumendæ. Rep. Med.

As she leaves town to-morrow, I advise her to apply six leeches to the anus, on the 27th, if there be much pelvic congestion. She was also furnished with the following directions:—

"I should wish Mrs. F., to carefully abstain from all excitement, both of body and mind. Except when walking, she is to be, as little in the upright posture as possible; so that while she is in the house she ought to be reclining on the sofa.

"I wish her to take a short walk regularly before breakfast, increasing its length according to her power, but never so as to cause pain or exhaustion. A plain biscuit may be taken on going out; and on returning, she should rest for some little time both before and after breakfast; during the day, she may ride out in an easy vehicle, in which she can recline considerably, and put up her feet; she must carefully keep the feet warm, and wear flannel or merino next the skin, as the season advances. Three days before each catamenial period, she is to take two of the pills marked 'calomel pills,' and a Seidlitz powder the next morning, and if she feels much pain and fulness about the hips and loins, to apply six leeches to the anus, and encourage the bleeding by the warm semicupium.

"Every morning, the back and abdomen are to be well sponged with tepid or cold water, and briskly rubbed dry, with a towel slightly impregnated with salt.

"She is to avoid all indigestible food, and, as much as possible, fermented liquors, a little sherry being the least objectionable, and keep early hours. If the bowels become confined, let her take some sulphur and magnesia."

Sept. 16th. (by letter)—Still much pain round the back and loins; but has not had darting pains for many days. Bowels constipated without medicine; pulse 84, very feeble, feels weak; but the twenty minutes walk before breakfast agrees well with her; leucorrhœa much less; the leeches did not produce much relief.

Rep. Lotio et mist. gentianæ c. acido nitrico.

R Ferri sulph. gr. ij., extr. lupuli gr. vj. M. ft. pil. ij. o. n. sumendæ.

Let her take once a week—

R Pil. hydrarg. chlorid. comp. extr. hyosc. aa. gr. v. M. Ft. pil. ij. h. s. s.

Oct. 15th.—Feels much better, but exertion still brings on pain of back; the catamenia appeared some days before the time, in consequence of some mental annoyance, followed by sense of fulness, bearing down, and darting pains about the pelvis, for which she applied five leeches with relief; feels weak; leucorrhœa is diminished; occasional attack of hæmorrhoidal congestion; appetite and appearance improved; the morning's walk has agreed well. Pergat.

Nov. 24.—In consequence of feeling so well, she has neglected taking her medicine for three weeks; the stomach has become deranged with much acidity; a dose of calomel which I desired her to take before the next catamenial period, has acted well and with great relief; the discharge was more free, and with little pain; the leucorrhœa now only appears for a short time immediately after the catamenia; it is less in quantity and thicker. She has no darting pains; the bowels are in a more comfortable state. Contin.^r omnia.

Feb. 24th, 1841.—Has been suffering much anxiety of mind from the loss of a relative; the darting pains have returned in spite of her having applied leeches to the anus; complains of severe pain over the pelvis, with bearing down and much congestive swelling of the vagina, which symptoms are evidently increased by cold; much lassitude and pains of limbs; great acidity of stomach; leucorrhœa has returned.

℞ Extr. colchici acetici gr. ij., pulv. guaiaci gr. viij. M. Ft. pil. ij. om. nocte sumendæ.

Rep. Mist. gentianæ c. acido nitrico. dil.

Let her take a teaspoonful of common salt, and half that quantity of carbonate of soda every morning in a glass of water for ten days.

March 18th.—Much better; "surprisingly free" from pain at the last catamenial period; leucorrhœa greatly diminished; any extra exertion causes bearing down; says that the salt and soda mixture has agreed well with her. Omitt. pilulæ.

℞ Hydrarg. c. cretâ, extr. anthemidis aa. gr.v. M. Ft. pil. ij. o. n. s.

Let her continue the salt and soda every morning.

June 17th.—Her strength has improved, and the menstrual periods have been much better; there is still a slight degree of leucorrhœa.

Shortly after this, she went to Aberystwith, and derived so much benefit from the change of air, sea-bathing, &c., as to consider her health quite re-established.

The symptoms at the commencement of this case struck me as indicating a state of ovarian irritation. The pain in the crest of the left ilium did not attract my attention peculiarly at the time, beyond supposing it to be more or less connected with the state of the left ovary, not then being aware how frequently, or, I might almost say, invariably, pain in this situation exists in connection with irritation or inflammatory action of the os uteri. In cancer, when the os uteri is undergoing gradual destruction from malignant ulceration, the pain of one or both hips is frequently one of the most prominent symptoms of the patient's sufferings; and it is a remarkable fact in confirmation of what I have now stated, that in three cases of amputation of the os uteri which I have attended, one of the first remarks of the patient after the removal of the part was that she had lost the pain in her hip, which up to that moment had been such a constant source of annoyance to her. In dilating the os uteri also, I have frequently observed the pain referred to the same spot. A knowledge, therefore, of this fact at the time would probably have induced me to request an examination at the first visit, even although the symptoms of inflammation of the cervix were by no means well marked.

My patient rather misled me regarding the effects of mercury upon her system, and it was only by degrees that I found out the error, the result proving that an occasional dose either of hydrarg. c. cretâ or calomel had the best effects.

On the 20th of August, the symptoms of inflamed cervix uteri had become quite distinct. The pain produced by sitting down on a hard seat, or during the passage of hardened fæces; the white creamy, or albuminous discharge, the lancinating pains, and painful state of the os and cervix uteri upon examination *per vaginam* formed a mass of evidence which marked the nature of the complaint.

The appearance of lancinating pains after using astringent injections is a good practical hint well worthy of attention, and shows that these applications are neither justifiable nor safe in every form of leucorrhœal discharge, and there is no doubt but that their continued use in cases of this sort would soon pave the way to alteration of structure and organic disease.

It is worthy of notice that inflammation of the cervix uteri is frequently attended with more or less hæmorrhoidal congestion, and that in both these conditions there is usually an excess of lithates in the urine which is deposited on cooling, and considerable derangement of the digestive organs. I mention this as confirmatory of the opinion which I have maintained in these reports and elsewhere, that topical congestive inflammation of these organs, except when it is distinctly the result of local irritation, is almost invariably connected with and dependent upon a state of derangement in the functions of assimilation. The application of leeches to the os uteri was attended with complete relief, the good effects of which however were in some measure injured by her indiscretion.

I find in my notes no prescription for the calomel pills alluded to in her directions, but presume they consisted of three or four grains of calomel with extr. hyoscyami, being in the habit of giving them in similar cases shortly before the menstrual periods. I have inserted the directions I gave her, at length, as they serve to show the points of her general diet and regimen, about which I was most anxious.

She continued to improve slowly, although occasionally thrown back by the effects of mental distress. Towards February, the pains of her limbs and attacks of congestive swelling of the vagina appeared to indicate an alteration in the character of her symptoms, and to justify the use of the colchicum and guiacum combination which I ordered. The morning dose of common salt and carbonate of soda was a rough imitation of sea water, and answered the purpose well. I know of no saline laxative which produces such a sensation of lightness and relief after its action as common salt, when combined either with the carbonate of soda or magnesia, and especially when taken in the form of sea water. I have heard from my patient several times since, and with one exception, for a short time, she has had no return of her complaint. She has since become pregnant, and was delivered of a living child last Aug.

The Society for the Improvement of the Condition of the Insane, 26, Cavendish-square, London, has, this season, awarded the sum of twenty guineas to Mr. Spencer Thomas Smyth, M.R.C.S., Gorleston, Suffolk, for the best Essay on the Pathology and Treatment of Puerperal Mania.

Gentlemen admitted members of the Royal College of Surgeons, on Friday May 2d, 1845:—W. S. Rootes, F. W. Barnes, W. C. Hunt, A. P. Cahill, T. Hall, F. R. Hoghton, N. C. Hatherly, W. B. C. Maxwell, R. Bentham.

Gentlemen admitted members of the Royal College of Surgeons, on Monday May 5th:—J. W. Bradshaw, G. Husband, H. Winterbottom, E. Nolloth, J. Frain, W. H. Young, W. Andrews, J. Gabb, H. Wilson, J. Evans, G. W. B. Calcott, W. Collyns, J. J. Cole, W. A. Barr, G. T. Gutthorpe.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

Attacks of epilepsy are sometimes periodical, coming on every week, or every month, and sometimes every other day; but in many cases they are irregular. It is more irregular in its occurrence, and also more common in men than in women. In some cases the fits are few and far between, and in others they are more frequent, and the more frequently they occur the more are they accompanied with the other symptoms of cerebral derangement, and where the fits occur frequently, in confirmed cases, a very remarkable expression is stamped on the features. They become coarse and enlarged; the lips are swelled, there is a rolling of the tongue, and a vacant idiotic stare of the eyes; even in the intervals of the fit there are various convulsive twitchings of parts, symptoms of partial paralysis, and other proofs of disease affecting the system, not only by the epileptic fits and convulsive paroxysms, but more permanently and continuously interrupting the functions of the brain and the spinal centre. Under such circumstances, there is no question at all that the disease is structural. On examination after death a great variety of things have been found; tumours in the substance of the brain, in the meninges, the cerebellum, and, in fact, tumours in all parts of the brain have been found accompanied by epileptic convulsions. I have known two or three cases of exostosis and general thickening of the skull, and tubercles, hydatids, and serous cysts, and also softening of the substance of the brain. In some cases of epilepsy, where the convulsions have been severe, there has been found nothing after death, and there can be no doubt that epilepsy is sometimes produced by a cause without the head, and likewise by causes of a temporary nature. Again, epileptic convulsions occur from great loss of blood, and in these cases there is nothing on the brain or its membranes to account for it; there is congestion, which may account for it, but there is no structural disease, and congestion may be the result of a temporary cause. Again, various poisons—alcoholic poisons—in extreme quantity produce insensibility accompanied by convulsions, and after death on examination of the brain nothing is found but the smell of the alcohol: there is no structural disease. Further, epileptic convulsions may be produced by causes without the brain, in other parts of the body, and in children epilepsy is habitually occurring. But convulsions that may become habitual have been produced by disorders of the intestinal canal, and gastric irritation, in adults. So, likewise, diseases of the liver and the gall bladder have been known to be accompanied by epileptic convulsions, apparently arising in some instances from irritation transmitted through the nerves, but probably in connexion with the liver, more particularly, perhaps so, in connexion with the intestines, arising from the poison in the blood from the retention of the excretions which the intestines ought to eliminate, and from the operation of this excrementitious matter in the blood on the nervous centres. Convulsions often occur in cases of suppressed excretion of urine and bile. The various affections of the uterus have been observed to be accompanied by, and to become the exciting causes of convulsions, and what are called puerperal convulsions appear to be quite of an epileptic character. Again, epileptic convulsions are produced at the various parts where the nerves have been much irritated, and it has been known to be traced to tumours pressing on a nerve. Another cause is calculus of the kidney. Almost any structural disease of the brain or of the membranes within the skull is occasionally accompanied by epileptic convulsions. Convulsions may occur and be ascribed to disease attached to the nervous centres, and these are called centric convulsions. In another case they arise from functional derangement of the brain or nervous centres. Such are those produced by great losses of blood, and by the opposite condition—plethora. These are central too. Likewise, the various moral emotions, and narcotic influences, are capable of producing the same thing, and may be called centric convulsions, inasmuch as the irritation is applied first to the centre of the nervous system, from which the convulsions emanate. Other cases may be called excentric convulsions, because the irritation proceeds from distant parts, and is circulated from those distant parts towards the centre.

I have said enough to prove that epileptic convulsions may occur in connection with structural disease or functional disorder. Now, structural disease does not produce convulsions continually, and there must be something superadded to the disease to produce that result; there must be existing a predisposing cause—a morbid condition—that remains in the individual,—which may be either structural or functional. This is one of the elements, and the action of this seems to be that of rendering the brain liable to a sudden suspension of sensorial power on the application of some additional influence, that being excitement from without, sometimes excitement from within. Sometimes it has been applied to the cerebral function itself, and at other times the influence has been applied to some other function producing derangement in the nervous system, and before this second cause is produced, there requires to be an additional circumstance which induces the fit, and without this additional circumstance, which may be called the exciting cause of the fit, the permanent cause, whether structural or functional, from any cause whatever, may last long, and yet no fit occur.

A case has been mentioned by Dr. Chambers, of a patient whose skull was fractured, and a portion of the bone was left depressed; under ordinary circumstances it produced no mischief, but if at any time the circulation of the brain became excited by taking a glass of wine or spirits too much, epileptic fits occurred. Here was the additional cause of excitement. The same may be said of a great number of cases where there is previous structural disease. Powerful emotions of mind and violent exertion, in persons predisposed to it, will induce the fit. The question is, how these different causes act? How the bony tumour can exist in the brain so long without inducing the fit, until some additional cause is in operation. Dr. Marshall Hall considers it to be a disease of the true spinal system,—that convulsions are an essential part of this disease, and that loss of consciousness is an epiphenomenon produced in the following manner:—that when the spinal function is affected only to a slight degree, convulsions are produced without loss of consciousness. This is the case with hysteric convulsions, and these he considers to be a lower form of the spinal affection. The spinal irritation extends to the whole spinal function, not only the vertebral spinal function, but to that connected with the medulla oblongata; so that if the function of respiration is injured or disturbed, a temporary state of asphyxia is produced, and, as the result of this, the sensorial functions are disturbed, and consciousness is lost. Now, the great objection to this is, that instead of convulsions being the foundation of the disease, the part most essential—the convulsions—are in many instances wanting. Take the instance of a loss of consciousness where there are no convulsions, and such attacks do occur in persons who are subject to epileptic fits. It is quite clear, therefore, that so far as relates to the true spinal system, epilepsy is a disease producing an irritation of that, as it produces a suspension of the sensorial function. The symptoms of asphyxia are by no means common in epileptic attacks. It is true, the face gets red and livid in convulsions, owing to the great disturbance of the respiratory functions; but this is not the case in the slighter form, and is by no means proportioned to the loss of consciousness. We must take it as assumed that the disease is a cerebral disease essentially, and that the fits which occur from time to time are commonly caused by something interfering with the circulation through the brain; this is the immediate cause that may at any time suspend its function. Stop the circulation of the brain, and the sensorial functions are suspended; excite its circulation, and the functions are over-taxed. We have traced this, in various degrees, throughout the phenomena of inflammation, increasing or diminishing the circulation of the brain.

Well, then, epilepsy appears to be the cause, obviously, of the suspension of the function, and we must assume then an interruption of the function of circulation through the brain; but there is an excitement of other functions. How comes this? Two opposite phenomena are produced in parts closely adjoining each other; we need not go far to explain this, for it is explained by conditions found to be present in a great number of cases of epilepsy. I have mentioned that in a great number of cases it is observed to be at first a paroxysm; determination of blood, beating of the carotids, palpitation of the heart, flushing of the face, and sometimes the face, instead of being flushed, becoming pallid, and even that occurs at the very time the arteries of the neck are beating strongly. Then the question comes to be, supposing the circumstances I have already mentioned, such as emotion, violent exertion, and other causes of determination of blood to the head act by causing this determination, how is it that it produces this opposite effect in the two parts of the nervous system—the oppression of one part and the excitement of another? Now, you recollect what I said on the subject of determination of blood, and the irregular distribution of blood in connexion with palpitation. There should be a proper proportion between the supply of the trunk and the branches of the blood-vessels, and when that proportion is lost to a considerable degree, instead of the circulation of the blood in the distant parts being promoted, it is diminished, increasing the size and length of the vessel instead of giving greater facility to the passage of the blood; the arteries at the base of the brain are dilated and lose their elastic tone, and some parts get more than their usual current. What are these parts? Why, the very arteries that supply the medullary matter of the spinal chord itself. It is the branches of the vertebral artery that come in for more than their reasonable share of the supply of blood. No wonder, then, that the functions of the upper portion of the spinal chord become unduly excited; whereas, that part constituting the extreme cerebral plexus loses its power, and is in the same condition with regard to determination of blood into the carotid arteries, as the arterial pulse in relation to the determination of blood to the aorta, and in common cases of palpitation you find it beating strongly at the aorta, whilst the pulse is weak at the wrist. How is it, then, you will be ready to ask, that these circumstances prove predisposing causes? How is it in extreme disease, after great losses of blood, these convulsions are produced by the same causes? For this reason,—the heart's power is weaker under these circumstances, and cannot propel the blood with the same force to the distant extremities; so likewise the quantity of blood already in the brain we have found to be disproportioned to the force which propels it, and under these circumstances this loss of balance between the distant parts of the circulation and that nearest the heart is increased more and more. The same thing may be said with regard to other causes of cerebral excitement, producing temporary convulsions. Tumours act in the same way. A tumour would be a mechanical agent; hence spinal irritation is produced by disease at the very top of the brain. There is no functional disorder produced, but when the determination takes place, the undue pressure will be quite enough to arrest the circulation altogether. Tumours act in another way; they operate as causes of determination of blood.

The prognosis of epilepsy will vary considerably in different cases. The fits themselves in the very worst cases are dangerous, especially in persons, of plethoric habit, and in very young persons, much the same as in persons of plethoric habit, apoplexy may ensue. In very young subjects where the respiratory apparatus is weak, and where laryngismus stridulus is present, asphyxia, connected with the convulsions, may prove fatal. The prognosis is worse in cases where in the in-

tervals there is no sign of cerebral or nervous disturbance. The prognosis is also unfavourable where there is congestion; and especially so in cases where there is disease within the head, and in hydrocephalus. Another bad case is, where the disease begins from injury in the head, from whatever cause it may arise. The diagnosis will depend on the loss of consciousness with the convulsions, and the severity of the symptoms I have mentioned. There are sometimes cases of epileptic attacks without convulsions, which the state of the breathing will enable you to distinguish. Dr. Marshall Hall says it is not much affected in these cases, and is not sterterous as in apoplexy. The pupil is dilated, but not always insensible to light. We may distinguish this loss of consciousness from syncope by there not being pallidity, and the pulse not being irregular. It is more difficult to distinguish cerebral from sympathetic epilepsy; I mean that connected with serious disease, from that which is excited by sympathetic causes. If the disease has occurred from a fall or a blow on the head, or from an attack of inflammation, or anything of that kind, or from hydrocephalus that has come on soon after birth, or if there are any other symptoms of disease of the brain, there is great fear there is structural disease that ought to be removed. One of the commonest causes of epileptic attacks is indigestion, or a disordered state of the stomach, connected with excitement of the head.

The treatment of epilepsy is to be considered in relation to the fit, and in relation to its recurrence. The fit if severe, may do mischief by the violence it causes. Persons affected with epilepsy ought not to be left alone. I remember a patient who was left in bed alone, and who in reaching over the bed to take his medicine, fell with his head considerably below the rest of his body, and in that state he was seized with a fit of apoplexy, and died. On the first attack coming on, the patient should be placed on the bed with the head raised up, and if the breathing is stertorous, blood-letting should be resorted to. The attack may be shortened by putting something in the mouth to increase the flow of saliva. It is proper to dash cold water on the head, and where the attacks are severe, cold applied to the head and warmth to the feet, act as derivants, as they reduce the determination of blood, and the other phenomena connected with it. To prevent the recurrence of the fit, it is of consequence to set about finding, whether there is any irritating cause in the system, producing the fit. Feculent accumulations will do so. If there is in the vascular system any fullness of blood, this should be reduced by blood-letting, and if there is determination to the head connected with palpitation or with excitement, it should be treated by derivants, keeping the secretions perfectly free. The stomach should be kept in a good condition, and we should prevent flatulence occurring by antacids and carminatives, as for instance hydrocyanic acid, tincture of henbane, quinine, and digitalis. Keeping the patient a great deal in the open air is of importance in the treatment of this disease, and the susceptibility of the nervous system must be kept down as much as possible by accustoming the patient to a regular quantity of exercise. Besides this, it may be necessary to use local depletion, cupping or leeching the head, or by blisters or issues. The diet in all cases should be moderate; light and nourishing food at moderate intervals, taking care never to distend the stomach, avoiding alcoholic stimulants, and generally promoting the digestion in every favourable way. When, in spite of this treatment the fit still continues; then the cause is an irrecoverable cerebral lesion. It has been attempted to cure this lesion—when produced either by a spicula of bone, or a tumour—by trephining, which has been successful in some fortunate cases.

Oxford University, with six medical professors, has, in *ten* years, made *twenty-two* doctors of medicine!—The Cambridge professor of anatomy has five pupils; the professor of chemistry, five; and the professor of natural philosophy, two!

The annual dinner of the Medical Society for the relief of widows and orphans, will be given on the 19th inst., at the Bazaar Coffee House, Covent Garden.

A COURSE OF TWELVE LECTURES ON SKIN DISEASES,

By D. J. Corrigan, M.D., Physician to the Whitworth, Hardwick and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

This evening we resume the subject of measles. This is a disease which never kills of itself, it is the complications which occur during its existence, or after it has disappeared, which prove fatal. One of the most common sequelæ of measles is scrofulous ophthalmia, with which, however, we have nothing to do here. The other more fatal consequences, or accompaniments of it are bronchitis, and that form of pulmonary inflammation known under the name of broncho-pneumonia. It is not necessary to go over the proper treatment of these affections here, as while on the subject of diseases of the lungs, we have done so at full length. The only treatment which it will be necessary for you to adopt in the premonitory stage, is the employment of mild purgatives to clear out the alimentary canal of all fœcal accumulations, afterward the exhibition of minute doses of antimonials to lessen the force of the circulation, and excite perspiration, by relaxing the skin, and you will materially assist this latter end by tepid sponging of the whole body with vinegar and water, which will prove most grateful to the patient as it very much lessens the itching, which is so troublesome an attendant upon the eruptive stage of the disease. There is an accident (or, to speak more correctly, an incident,) which occurs occasionally during the progress of measles, which, however, is not essential to it. As I have said in the prefatory lecture to skin diseases, we must only take into account in forming our diagnosis, those characters, which are essential to the disease, not those which may fortuitously accompany it. To exemplify what I mean. In a hospital you may have at once twenty cases of measles, eighteen of which shall present nothing out of the ordinary routine of symptoms, while on examining the other two, you will find across the loins, myriads of minute vesicles, which feel rough to the touch, but seem to the naked eye but so many elevations of the cuticle. When, however, they are examined with a microscope, they are found to be filled with a clear serum; these vesicles become somewhat larger, when the serum becomes turbid, and after a day or two they are absorbed, and the cuticle degenerates. These vesicles, which are of a trifling character, are sometimes seen in the axillæ occasionally, and require no treatment beyond that proper to the disease itself. The appearance of these vesicles in measles would seem to depend upon the irritation which the pressure of the bed upon the under skin excites, just as we find in fever, the skin in the same parts, liable to take on a much more dangerous form of inflammation from the same cause. The next variety of measles, rubeola nigra, would seem to depend upon the admixture of spots of purpura hæmorrhagica among the genuine stigmata of measles; the fever which accompanies it is always more or less of a typhoid type, and this you will do well to remember, when called upon to treat the disease. These spots of purpura are again absorbed on the disappearance of the eruption. The complications which may arise during its career, call for no line of treatment other than that to be pursued under the same circumstances in R. vulgaris. R. sine catarrho is the best division of this subject. This is said to be a form of measles where the eruption appears, unattended, however, by the catarrh and fever which accompany the other varieties. This form of the disease (as it is said to be) does not guarantee a person from taking either of the catarrhal varieties, provided they come within the range of its power of infection; I, for my part, do not think this a variety of measles at all; I should be inclined to consider it nothing more than roseola; however, Bateman has plates of it as it appears on the face, presenting all the characteristics of genuine measles. Its treatment requires merely confinement to the room during the period of the eruption, and the use of slops.

Scarlatina comes next in order. This most interesting disease has been divided into three varieties, S. Simplex, S. Anginosa, and S. Maligna. This division is felicitous, and one very well adapted for practical purposes. In S. simplex we find the body covered with a red colour as here (showing some plates)—all the characteristics of scarlatina are here known by diffused redness over the body. We know that it is before us, and we know no more. Scarlatina simplex is ushered in by cough, sneezing, watering of the eyes, slight sore throat, and then the eruption appears. The stages of this disease, as in measles, are three. The stage of incubation or germination seems to be the same in both, but in the premonitory stage there is a material difference, and one which it is highly necessary for you to know, as it forms a principal point of distinction between measles and scarlatina. In the former, the premonitory stage extends over a period of at least three days. while in S. simplex it, in my opinion, never exceeds twenty-four hours. The lunated, or crescentic shape of the stigmata in measles, will also present itself to you as a means of enabling you to judge between both, though this is sometimes a sign difficult of recognition when measles are thickly scattered over the body. In this form of scarlatina the skin presents a vivid red colour, and the eruption is but sparely scattered over the body, the interstices of skin presenting the natural hue, while in other cases the body becomes covered all over with the eruption, and of a hue so vivid as to give the arms and legs the appearance of a boiled lobster, while in other cases these parts present a faint tinge of colour. This eruption continues out for three or four days, first appearing on the face and neck, and thence travelling to the trunk and extremities, finally ending in desquamation: during the continuance of this form of scarlatina the constitution is scarcely, if at all, affected. Its treatment consists in confining the patient to his room, clearing out the bowels by mild laxatives and ordinary diluents. There is a form of S. simplex where the eruption appears but for a very short period—so short, indeed, as frequently not to be noticed; where the constitution at the time is not at all affected, but where, nevertheless, in some short time after its disappearance—say eight or ten days—I have seen the usual œdema of the legs take place; I mean that œdema which so often sets in after other varieties of this disease. In such cases I have found this sequela much more dangerous and difficult of removal than when it has occurred after the other varieties, and that effusion into the cranium has more frequently taken place here than in the other forms of the disease; this effusion, in most instances, being denoted by coma and convulsions.

S. Anginosa next claims our attention. Of this there are three sub-varieties, named according to the appearance which the throat may present. The first is where the tonsils are but slightly inflamed, presenting nothing which would call for any particular treatment on this account; this variety is but of little importance. The next is the diphtheritic, and the last is a form of which I shall speak by-and-bye. In the diphtheritic variety, on or about the third or fourth day of the disease, the patient will complain of sore throat. On examination you will perceive the inside of the fauces, the velum pendulum palati, and the back of the pharynx, covered with what you would at first be inclined to say was ulceration. But on a more minute inspection, or on wiping off the adhering matter with the handle of a spoon, or with a probe, you will find it to be nothing more than "pasty lymph," underneath which the parts previously covered by it are highly vascular and red, but not in a state of ulceration, while they continue to secrete copiously the lymph. This state of the mucous membrane is very apt to extend itself from the left palate crossing down to the root of the tongue, thence reaching the larynx, when it gives rise to symptoms exactly analogous to those of croup. The same secretion of pasty lymph takes place along the trachea, as along the mucous membrane of the mouth and fauces, and very often in such quantity as to prove quickly fatal. Bretonneau, and some others, misled by the appearances found in the trachea after death, have stated that this

diphtheritic form of scarlatina is nothing but croup. This is an error. Although the pathological appearances discoverable in both after death are the same, yet from this fact we must not suppose that the diseases producing them have been the same. Identity of pathology in any two instances should not lead us to infer identity of disease in each. In two cases of pneumonia, which may have proved fatal at a similar stage of the disease, we shall find the pathology of both identical. In one, a case of acute pneumonia, death has set in at the first or congestive stage of the affection; the other is a case of pneumonia typhoides. In both these instances the lungs shall present the same appearances; they are dark-looking, heavy, and sink in water, and in a state of congestion; when cut into, their cells are found filled with a bloody serum; they both are soft to the fingers, and still crepitate under it. Surely no one can or will say that the two diseases producing those exactly similar states of lung have been, or are, identical; and just as rational would it be to suppose with Bretonneau and his followers, that because the extension of diphtheritis to the larynx and trachea has in this form of scarlatina, produced symptoms analogous to those of croup, both diseases must be similar. It will be extremely important for you to prevent here the spreading of this diphtherite to the larynx, for once it has reached it, it proves quickly fatal; no effort of yours can arrest it. For this purpose, as soon as ever the first appearance of this lymphy secretion takes place within the fauces, you must apply nit. argenti in a solid state, both outside and upon these patches. Than lunar caustic I know no application more efficacious in preventing the extension of false membranes. It is not easy to explain how it is that caustic acts so beneficially here. Perhaps it is that the parts having been thrown already into a state of irritation approaching closely to inflammation, owing to the virus of scarlatina, become more sensitive than natural to the action of caustic. This action, we know, is not to increase the existing secretion of the greyish lymph of diphtherite, but to produce a secretion totally different, namely the whitish one which we invariably see produced on mucous membranes to which this mineral irritant has been applied, and this latter action being more powerful than that of the cause producing diphtherite, thus removes the latter; beside, the mucous membrane of the mouth, we frequently find other parts of the capillary system labouring under the secretion of this lymph. During the prevalence here of the epidemic of scarlatina, I perfectly recollect seeing numerous instances where the skin (which you know approximates very closely to the nature of mucous membrane) secreted this lymph. The subcutaneous cellular tissue became inflamed, patches of skin became elevated from accumulations of serum, underneath which pasty lymph was secreted, just as in a blister when the serum is allowed to escape. This form of S. anginosa is sometimes attended with green vomiting and diarrhœa. These are unpleasant and dangerous symptoms, as they show that this diphtherite has not only reached the pharynx and fauces, but has also travelled to the stomach and intestinal canal. Then along with the application of nit. argenti to the fauces and throat, you must apply leeches and blisters to the pit of the stomach, and over the abdomen. If the tongue be dry, you will give mercury to restore the secretions, and as soon as the gastric symptoms have been subdued, you will bear in mind the necessity of prescribing bark, for the fever accompanying this form of scarlatina, is always one of a typhoid type. In lectures such as these, we cannot enter into the minutiæ of treatment necessary in this disease; it is impossible for us to do so; the wards of our hospital are the proper place to acquire the amount of information necessary on these heads: all we can do here is to lay down general outlines, which must be left to observation and practice to fill up according to the exigencies of each particular case. There is another variety of scarlatina anginosa, which, as far as I am aware, has not been sketched by any writer, but which I shall endeavour to do so for you, as far as my own observation will allow me. On the 5th, 6th, 7th, 9th, or 12th day, either during the progress or after the disappearance of the eruption (it is uncertain when it may occur), a child ill of the disease will present the following symptoms:—you will be told that it has been sleepless for the last few nights; it has become irritable; and whines incessantly; you will find its pulse to have risen in frequency while it has become weaker than natural.

The parts beneath the angle of the jaw begin to swell; this continues to increase. If you examine the part in twelve hours after, you will find it to have increased more; look at the throat now, and you see nothing there beyond the usual concomitant of the affection, or the throat may be perfectly natural; in twelve hours more, you will find the swelling to have increased still further, and to have extended itself up towards the ear. It continues to get larger and larger, until the angle of the jaw becomes completely obliterated from the swelling of the parts beneath it; this gives the child a peculiar appearance somewhat like that of an old member of the monkey family. In this state of things when drink is given to the child, it is returned through the nose, owing in all probability to the extension of this peculiar swelling to parts about the pharynx. This swelling, when pressed upon by the fingers, gives the fluctuating feel of fluid to them. This arises from the natural œdematous sensation which extravasation of serum in any part gives rise to, when the finger is pressed upon it; this it is that takes place here, and not only does this infiltration of serum take place within the cellular tissue, immediately outside the fascia, but also the parts beneath it become the seat of this effusion, even to the cellular substance forming the matrix of the muscles of the neck. With this state of the parts, the skin covering this enormous tumour is sometimes red, and quite as often of the natural appearance. There is no value to be set upon this. Matters continue to get worse from day to day until the child dies, from inflammation and subsequent sloughing of the cellular tissue covering the tumour; when this occurs, it frequently leaves the subjacent muscles as free from every trace of cellular tissue, and as clean as ever you saw them exposed by an expert anatomist in the dissecting-room; or the child may die without this sloughing at all, probably owing to the pressure which this tumour exerts upon the vessels of the brain, which produces a state of congestion in that organ which quickly kills, or it may be carried off, solely by the irritation which this large tumour excites. Death here, cannot be owing to any impediment which may exist for the passage of air through the trachea, for although the extravasation of serum may travel toward the trachea, and larynx, producing distension of the cellular tissue in their neighbourhood, still this never takes place to such a degree as could lead us for a moment to suppose that death could be owing to this cause. If, tempted by the feel of fluctuation, you should be led to make an incision into this tumour, you only give vent to a very small quantity of dirty serum, and this cut instead of proving beneficial will be highly injurious. Recollect that it is no common abscess that you have before you. You have the cellular tissue underneath the jaw, distended with serum, which is diffused all through the surrounding textures. Here an incision, owing to the seat of the effusion, will not serve to set it free; it cannot do it, and, by having made an incision, you will have added very much to the irritation already existing, by superadding a new source of mischief—a wound, which the constitution, already sinking under the previous affection, will not be able to hold up against. This is not a common abscess, which has limits set to it by the extravasation of lymph, by which the matter becomes encysted, and the walls of the cyst become thinned to allow the escape of the matter. Here you have no bounds set to the tumour. It reaches from the ear down below the angle of the jaw, involving all the tissues above and beneath the fascia in its progress. During the prevalence of the epidemic of scarlatina, we made it a rule in the Whitworth hospital, where we had a good many cases of this kind, never to open the tumour. Conviction of the necessity of this forbearance of the lancet was forced upon my notice at length, from observing the invariably fatal results of these cases where large incisions had been made. Therefore it was, that this rule was adopted by us, never to open tumours of the kind, but to leave them to nature. Indeed, you may as well do this as anything else, for such is the fatality of the disease, that in all my experience I can call to mind but one case which did not prove fatal; and in this solitary instance the disease was not fully formed. When once it is so, all that you can do to save the patient is of no use, perfectly unavailing; and in these cases, you may as well leave them quietly to their fate. I may safely say that ninety-nine cases out of every hundred such are surely fatal. I have been frequently told by persons, that they have repeatedly cured patients labouring under this form of scarlatina. If so, their success has been greater than mine; for, as I have already told you, out of a very large number of such cases, I can call to mind *but one recovery*. I am inclined to think that for the one in question, they have mistaken another and quite different affection. I mean inflammation of the glands under the jaw and ear, from which recovery so often takes place. But this is not the form of disease of which I have been speaking. In glandular inflammation after scarlatina we have circumscribed swellings, the swollen glands feeling like so many eggs under the skin, and if the skin covering them become affected, it is merely by an extension of the inflammation from the body of the gland to the cellular tissue in question.

But in the form of inflammation which I have mentioned, as proving so generally fatal, we have none of that circumscribed tumour; on the contrary, it extends along the whole track of tissue from the ear to the jaw, and in place of pus being secreted, as in glandular inflammation, as I have said before, nothing but a dirty serum is found. Such glandular abscesses we can open readily and beneficially. Why is this? Because the boundary of such an abscess has been distinctly defined, the matter collected in it has not become diffused through the cellular tissue, as in the form of which I have spoken, but becomes a regular encysted abscess, which, when opened, freely discharges the matter within it. I repeat, that the form of diffuse inflammation of the cellular tissue of the jaw and ear, accompanying this variety of scarlatina, is, I may say, invariably fatal. As we cannot cure it, our object should be to try if we cannot prevent it. Indeed, with regard to this latter step either, I do not know what to say; as all we can do will prove but of little service. The plan of treatment which I have found most useful is as follows: before detailing it you must bear in mind, that unless you can put it into operation at the outset of the disease, it will not be of the slightest use. On the first appearance of swelling under the jaw, you must apply leeches to the tumour, in the manner which I have mentioned when speaking of a variety of croup. The leeches here must not be put on in large numbers; this would not answer. apply them in relays, three or four at a time, in such a manner as that there shall be from the part a continual weeping of blood, in order that by this means of depletion you may guard against any engorgement of the vessels of the part, which would otherwise be sure to arise. Unless, as I have remarked, you apply the leeches early in the disease your efforts will be completely fruitless. The only preventive of this form of diffuse inflammation which I can recommend to you, is the early application of leeches, and in ninety-nine cases out of one hundred even these fail in checking its progress.

Mr. Muntz in the House, lately "gave notice that in committee on the Physic and Surgery Bill, he should move a clause providing that all medical practitioners shall write their prescriptions in plain English—(laughter)—and that all druggists and apothecaries shall have their bottles and jars labelled in plain English, after the 1st of January, 1846. (Laughter.)"

The Sanatorium in the New-road has been given up; another is proposed to be established by the committee.

RESTORATION OF NERVOUS INFLUENCE IN AUTO-PLASTY.

BY A. S. JOBERT DE LAMBALLE, D.M. P.M., A.M.

Officer of the Legion of Honour, Consulting Surgeon to his Majesty the King of the French Chief Surgeon to the Hospital St. Louis, &c.

(This Memoir, read before the Academy of Sciences, sitting of the 10th February, 1845, was revised by the Author expressly for the *Medical Times.*)

In a work published some years ago, I examined a question relative to subjects of the highest importance in physiology—I mean, *the cicatrization of the nerves, and the swollen extremities of the same when divided.* The question, in fact, is to ascertain whether the plastic forces furnishing the elements by which the solutions of continuity of our organs are repaired, are sufficient to restore the normal functions of a portion of a nerve when destroyed, or simply divided; and supposing that it be solved negatively, there remains to be examined the question, whether, after their division, the nervous action is restored in the parts situated below the wound, and if so, what means nature employs to obtain this restoration.

I think that I succeeded, in the work just quoted, in refuting the opinion of physiologists who admit the reproduction of the nervous substance. However, the experiments so skilfully performed by M. Flourens showed that sensibility may be restored in a nerve when divided; and established an apparent contradiction between his physiological conclusions and the anatomical facts observed by myself—so much so, that this part of the science was still enveloped in much doubt; but at the present day, if I am not greatly mistaken, all difficulties may be removed. During the last six years I have continued to examine this question, performing numerous experiments, and placing myself in a position not only better adapted to furnish conclusive results, but likewise to give to the subject greater weight and importance.

To obtain these results, I took advantage of the resources offered by experience on the various autoplastic methods with which contemporary surgery has been enriched. Instead of dividing the nervous filaments, I took in the midst of the living tissues portions of the integuments, of more or less size, and I applied them on bleeding surfaces, leaving only a narrow pedicle which performed the part (if such an expression may be employed) of a root to the divided portion, until new connexions were established,—until the animal graft was firmly united. Union having taken place, I then divided the pedicle, and even removed a portion, and obtained thus, in the midst of the living tissues, an isle, as it were, of organised substance, which could receive the elements of its nutrition, and communicate with the nervous centres, only by the medium of a cicatrix. Finally there remained—to note the phenomena which were produced in this animal graft—to examine whether the sensibility was diminished, and re-appeared with the nutrition, and to determine anatomically by what means the communication with the nervous centres was established. These questions will be answered by the detail of the following cases, which were likewise confirmed by experiments performed on animals:

CASE 1.—A young woman, ætat. 21, entered my wards on the 25th June, 1844, to be operated on for an ectropium of the left upper lid; the deformity, consecutive to a burn, left the eye quite uncovered; the ciliary edge drawn upwards, caused the lid to form an angle, the apex of which was fixed to the eye-brow, and the base the swollen and inflamed conjunctiva. The operation was performed on the 2d July, 1844, as follows:—The swollen portion of the conjunctiva was removed, and the lid detached from the superciliary arch; a portion of skin was next taken from the temporal region, and fixed between the two edges of the division; the lids and the cheeks became swollen, and union by the first intention took place. On the 12th July, the premonitory symptoms of an eruptive fever appeared, followed by pustules of confluent variola. This circumstance permitted me to observe the following curious fact: that imperfectly developed pustules did not appear on the flap before the 20th July, and only when the whole surface of the body was covered. On the 21st, the cicatrix which united it to the neighbouring parts was destroyed, and though it was surrounded by a furrow which suppurated, still it was not entirely detached. The sensibility of the pedicle at this period was perfect, but somewhat more obscure in the remainder of the flap. August 1. The crusts began to fall. 6. The furrow which surrounded the flap was nearly filled up, and cicatrization had commenced anew. 9. The nutrition of the flap seemed to be perfectly established; the pedicle was therefore divided: the part which remained united to the temple retained its sensibility; it became paler and insensible since, and shrunk when touched with lunar caustic; pain was felt when it was pricked with a pin. If the latter was forcibly pressed on the part, the patient stated that it was no longer a prick she felt, but a gentle pressure, a phenomenon which I attributed, not to the sensibility of the flap itself, but to the sensation received by the subjacent tissues. These trials repeated on the following days, had a perfectly similar result. Finally, in the beginning of September, the circulation re-commenced in the flap, and with it the sensibility was restored. To resume—1° *Application of the flap.* The sensibility is feebly retained in the pedicle, and disappears in the remainder of the flap. 2° *Division of the pedicle.* The flap shrunk, and its sensibility ceased completely, reappearing as the circulation was restored. These phenomena, relative to sensibility, will be observed accompanied by other peculiarities.

CASE 2.—A man, ætat. 45, entered the hospital St. Louis on the 3d December, 1840. Eighteen months before, he had the left side and arm dreadfully burnt; this accident, after producing suppuration for some time, ended by cicatrization, abnormal adhesions being formed, by which the arm was firmly attached to the side, to the extent of about three inches, a circumstance which rendered the movements of the limb very limited. On the 17th December, the large cicatrix which united the arm to the trunk was divided, and a large flap having been cut from the thorax, just above the nipple, its pedicle was twisted, and it was fixed in the wound. Towards the middle of January, the patient was seized with erysipelas, which affected the whole surface of the flap, and finally disappeared towards the end of the same month: at this period, sensibility, which was almost extinct in the flap, was very manifest in the pedicle. On the 22d February, the pedicle was cut; three days after, the distance between the edges of the division was upwards of an inch, and the patient could raise his arm to his head; sensibility scarcely existed in the flap, especially towards its centre, and remained very uncertain during the whole of the month of March. July 21, 1843, about two years and a half after the operation, the sensibility was as highly developed as in the surrounding parts. The movements of the left arm were almost as extensive and as free as those of the right; the flap which formed the anterior surface of the axilla retained all the characters of the integuments of the thorax, and under the influence of cold, the phenomenon so well known under the denomination of *chair de poule* was produced.

CASE 3rd.—*Cancer of the palpebra inferior; extirpation of the lid; blepharoplasty.*—Taillot; ætat. 51; rural guard; entered St. Louis on November 14, 1839, to have a tumour of a malignant nature, situated at the inner canthus, removed. The details relative to the development of the swelling, and the operation having been already published, need not be repeated.* I will only state that the fibres of the orbicularis having been involved in the disease, the greater part of this muscle was removed during the operation, and the flap was taken from the superior part of the malar region. Inflammation of an erysipelatous nature appeared on the temple, and attacked the parts around the flap, causing them to swell; there was not any pain in the flap, though sensibility still existed in the pedicle. The tumefaction soon disappeared; the vitality of the new lid was established by the adhesions which took place on all sides, and sensibility then returned; finally, a few fibres of the orbicularis remaining, the patient was able to close his eye. About a month after the operation, erysipelas appeared a second time on the right side of the face, and this attack gave rise to a very extraordinary phenomenon. The erysipelatous inflammation which attacked the patient soon after the operation, presented its maximum of intensity on the parts *around* the flap; the second time, on the contrary, the phlegmasia was highly developed *in* the latter. It would appear that on the first attack the vitality of the part was too feeble to furnish the elements of true phlegmasia, whilst on the second, the vascularity of the flap being highly developed, the inflammation was in proportion to this increase. Thus we perceive that inflammatory phenomena undergo, in autoplastic flaps, the same phases as nutrition and sensibility, and I could quote numerous cases proving that the development of horny productions on the flaps takes place in the same way, and that they may, like the vascularity and sensibility, be exaggerated. Graefe, and M. Dieffenbach were evidently mistaken when they stated that the hair which was on the flap, fell as soon as it lost all connexion with its primitive position. This may, it is true, take place sometimes immediately after the division of the pedicle; but I can assert I constantly remarked that the hairs on the flaps acquired a far more considerable development than before the portion of integument had been removed from its natural situation. Two of the cases which follow are proofs of the truth of this assertion.

CASE 4.—*Ectropium of the palpebra inferior: Blepharoplasty; extraordinary development of the hair on the flap.*—Désiré Islard, ætat. 20; affected with ectropium of the right lower lid; was operated on by me in 1835; a flap taken from the malar region was employed to repair the deformity, and what is remarkable, the fair silken hair which existed on this portion of the integuments previous to the operation, grew four or five lines in the space of three or four months, and became darker than on the opposite malar region.

CASE 5.—Mad. Hubert, ætat. 53, entered St. Louis on April 7, 1840, for a cancer situated at the outer canthus of the left eye; which began in 1824, and for which several distinguished practitioners had been consulted. After a careful examination of the part, I determined upon extirpating the tumour; and in order to replace the loss of substance which, of necessity, would be produced, I made a new lid with a portion of the tegumentary surface, taken from the temporal region. The wound healed by the first intention; six weeks after the operation, I divided the pedicle. In July, 1840, (four months having elapsed,) I remarked that the portion adherent to the temple was exquisitely sensible, though the flap was perfectly insensible. The patient was discharged cured. Two months after the operation, I examined the parts, and found that the vascularity of the flap had considerably increased, and that its sensibility was excessive. The disease relapsed, and the patient came back to St. Louis in 1841; but it is worthy of remark, that the cancer did not develope itself on the part it occupied previously, for instead of the outer, it affected the inner, canthus, without attacking the autoplastic flap. This second cancerous tumour was extirpated, and the loss of substance repaired by a flap taken from the root of the nose; re-union took place by the first intention, and the patient left the hospital apparently cured; but six months hardly had elapsed ere she experienced lancinating pains, proceeding from the interior of the orbit, and the state of the eye becoming daily worse and worse, she came for the third time to St. Louis on August 20, 1842, her sight completely lost. I was obliged to extirpate the eye, which operation was performed on September 8, and the patient was discharged cured on October 15. I saw her again on February 1, 1845, and then she stated that she saw much better with her right eye, than before the extirpation of the left. As to the artificial lid, it had the shape of a longitudinal tumour of the same colour as the healthy skin covering the surrounding parts; it possessed sensibility, for the slightest touch was felt by the patient; and

* Vide. Gazette Medicale, vol. viii., page 41, 1844.

its vascularity was considerable, since the prick of a pin caused several large drops of blood to exude.

This case evidently is, in every respect, similar to the preceding, as far as sensibility and vascularity are concerned; besides which, a curious peculiarity may be remarked: that the cancerous diathesis seemed to retreat before autoplastic flaps, as if the vitality of the tissues were regenerated by the animal graft. I consider this fact worthy the attention of surgeons, the more so as it is not the only one in which a similar result was obtained. I had an opportunity of examining a woman, named Ducreux, on whom Professor Blandin performed rhinoplasty, in October, 1841, to restore the soft parts of the nose, destroyed by lupus; the flap was taken from the forehead; the operation succeeded, and the patient thought herself cured. But about nine months ago a fresh tubercle made its appearance, on the point of junction of the cheek and the left artificial *ala nasi*, invaded the lip, was followed by other tubercles, and at the present moment the nose is surrounded with ulcerations which respect that organ, though they destroy the surrounding parts. The sensibility and vascularity of the skin covering the nose are considerable, and its inferior portion, taken from the scalp, presents a few hairs, which, far from falling, have, on the contrary, become more developed.

I will now give the details of a case of autoplasty, which not only confirm the preceding ones, but renders them complete, inasmuch as the *post mortem* examination enables me to give a description of the anatomy of the tissues, on which autoplasty was performed.

CASE 6.—A washerwoman, named Lambert, ætat. 23, entered my wards for the first time in April, 1835. Eight months before, this woman, who presented all the characteristic symptoms of the scrophulous diathesis, had been affected with an ulcer of the upper lid, which was followed by ectropium. At her entry, the parts were in the following condition:—conjunctiva palpebralis fungoid, and highly irritated; conjunctiva ocularis, red and swollen; ulceration of the superciliary region, which had destroyed the whole eye-brow, with the exception of about half-an-inch of its internal portion. The loss of the eye being imminent, I determined upon performing blepharoplasty; an incision was made on the lid, and a flap, taken from the cheek, was placed in the wound, and kept *in situ* by three sutures; the lost eye-brow was repaired by a flap taken from the temple. Both operations succeeded; the eye could be covered by the new lid, and the fibres which remained of the orbicularis enabled the patient to close it as readily as that of the opposite side. The eye-brow was as regular as its fellow; and this is easily explained on reflecting that the flap was taken from the edge of the scalp, and so fixed as to replace the destroyed brow by a row of hair. These, about sixty in number, were vigorous, and by cutting them from time to time, an eye-brow was formed quite as regular as the other, though somewhat more spare. With the exception of the pedicle, both flaps were insensible after the operation; sensibility was restored gradually, disappearing on the section of the pedicle. Finally, with respect to the restoration of the nervous powers, I verified, in 1844, the following facts, just before the death of the patient:—1° Vascularity in the two flaps, more highly developed than in the surrounding parts; the prick of a pin caused several drops of red blood to escape. 2° When pricked, the patient experienced a smart pain, and was never mistaken as to the precise spot touched. 3° The same phenomena, except the pain and hæmorrhage, were produced when the surface of the flaps was touched lightly with a feather.

On March 13, 1844, I was enabled to complete this case by the anatomical examination of the parts. The woman having died from phthisis, I performed the autopsy, and a careful dissection of the fronto-palpebral regions gave the following result. On examining the divisions of the ophthalmic branch of the fifth pair, I found that the lacrymal nerve sent a branch parallel to the palpebralis, but that none of its divisions anastomosed with the latter; the internal branch of the frontal nerve could not be discovered either in the palpebral flap nor beyond it, for in all probability, being subcutaneous, it had been divided and was atrophied; the external branch of the same nerve, situated between the periosteum and the muscles, still existed; it passed under the superciliary flap, and sent towards it several filaments which had been divided near the cicatrix, where they ended by a small swelling, without entering the flap. The nasal nerve, which had no relation whatever with the flaps, presented nothing abnormal. The orbitar branch of the superior maxillary, gave off several temporal filaments, which almost always encircled the palpebral flap without entering it. One of these filaments, cut close to the edge of the flap, terminated suddenly near the cicatrix, and could not be traced any further.

It may therefore be concluded:—1° That none of the nervous filaments belonging to the flaps could be discovered. 2° That none of the nervous filaments of the neighbouring parts penetrated into the flaps, all stopping suddenly when they reached the edge of the cicatrix. 3° That no nerve could be discovered in the cicatrix, but only vascular ramifications. 4° That the palpebral flap presented all the properties appertaining to the skin covering the external malar region, from which it had been taken; the superciliary flap likewise offered all the characters of the integuments of the temple, being only somewhat more vascular.

These anatomical facts, so curious when compared with the phenomena observed on the living subject, nevertheless required confirmation, and with this view I performed a series of experiments on animals. On a goat, I performed the operation of autoplasty on the left cheek, on June 4, 1843. On July 2, I performed a second on the nose, and a short time after, a third on the chin. I need not recapitulate the phenomena observed before and after the section of the pedicle, since they were in every respect similar to those already related. The animal was killed in February, 1844, and the parts were in the following condition. *Left side*; the seventh pair was swollen, and attached to the cicatrix of the flap; a very large branch issued from the infra-orbitar foramen under the flap, sending no filaments to it, but numerous branches describing semi-circles, their convexity directed downwards, passing towards the nasal flap. *Right side*; after dissecting the platisma-myoides, two thin nervous filaments were discovered, describing a circle towards the dorso-nasal flap; the inferior was at some distance from the nasal graft, and the superior went towards it. As to the branches of the ramus mentalis, they were spread out like a fan, and were distributed into the labial papillæ; one filament alone of the left ramus mentalis went towards the infra-mental flap.

On the 16th May 1844, I performed autoplasty on another goat. I took from the left commissure and the upper lip a triangular flap which I fixed by several sutures in a vertical incision, made above the spot from which the flap had been detached. During the operation, a good deal of blood flowed, and the flap which was supplied with blood by a large artery, still retained a certain degree of sensibility.—29th The flap which was shaved before the experiment, is united, and though still insensible, begins to be covered with hair; when pricked, no blood flowed, and it appeared shrunk and harder than in the normal condition; this firmness was evidently owing to the inflammation which had taken place in the midst of the tissues.—29th June. The flap is covered with hair; sensibility developed as before the operation; the prick of a pin caused an abundant flow of red blood—10th July. The pedicle was divided, an operation which produced an abundant hœmorrhage; the flap shortly after pricked with a pin, gave no pain, and a very small quantity of blood escaped through the opening.—9th August. The flap was covered with hair in every respect similar to that of the part from which it had been taken; sensibility was restored, for the animal when pricked expressed by its cries the pain it felt, and bright red blood escaped by the wound.—5th October. The animal was killed, and the flap having been dissected, the following facts were discovered. 1° The infra-orbitar nerve was divided into two principal branches; the *superior* distributed to the lip and the corresponding nostril, but without giving off any filament to the autoplastic flap; the *inferior*, sub-divided into three smaller branches, had a more direct connexion with the flap; the first went round the flap, and was distributed into the edge of the lip; the second seemed to proceed towards the inferior edge of the flap, where it terminated by a ganglionic swelling; the third on reaching the spot where the pedicle had been divided, turned abruptly back, and anastomosed with a branch of the facialis.

2° As to the seventh pair, after issuing from the parotid gland, it did not give off any branches to the flap. The terminal ramifications of this nerves in the lip and cheeks could be traced to the circumference of the flap, but none were perceived to penetrate it.

En resumé, from the numerous facts observed on man and confirmed by experiments on animals, the following conclusions may be drawn. 1° That immediately after autoplastic operations, sensibility is diminished or disappears in the flaps, and this is in a direct ratio with the loss of blood. 2° That before the division of the pedicle, sensibility is retained, if not entire, at least in part. 3° That a certain time after this division, vascularity and sensibility re-appear simultaneously in the flap, and increase in an equal ratio. 4° That in many cases, the vascularity is very great in the flap, and then sensibility is developed in an equal degree.

On the other hand, those furnished by anatomical examinations are. 1° That autoplastic flaps, after the division of the pedicle, are isolated on all sides from the surrounding parts by a layer of tissue in the cicatrix. 2° That the only means of communication which exists between the flap and the remainder of the organism are the more or less developed vessels which traverse the cicatrix; no nervous filaments are to be seen. 3° That the nerves which previously existed in the flap become atrophied and may even entirely disappear. 4° That the nerves of the surrounding parts do not extend beyond the cicatrix. Sometimes they terminate abruptly, offering a sort of neurilematic tumour; at others, they may be traced into the cicatrix, but *never beyond*.

This physiological observation teaches us that sensibility re-appears in the flap, and anatomy proves that the nervous continuity is not restored. How can this continuity be produced in a part entirely separated from the nervous centres? How can the sensations produced in this part be transmitted to the central portions of the system through a tissue deprived of nerves? These two questions are related to the highest and most mysterious physiological acts, and though I do not pretend to be able to elucidate them completely, still I think the two following propositions may be advanced, as the exact expression of the facts contained in this memoir. 1° The autoplastic flaps receive in a direct manner, the elements of their sensibility from the globules of blood which nourish them. The development of the sensibility is regulated by, and increases or diminishes in an exact ratio with, the quantity of the globules which reach the flap. 2° The sensations produced in the flaps are transmitted to the nervous centres by the extremity of the nerves which surround the cicatrix, and reach these extremities through the medium of the tissue of the cicatrix, though this part contained no nerves.

I will quote in support of the first of these propositions, the following theory. It has been proved by MM. Dumas and Boussingault that respiration is a genuine chemical combustion. Now this chemical action cannot take place without electricity being developed, and hence the origin of animal electricity. When the muscles are full of blood, there is a local combustion, causing a development of the electric fluid in sufficient quantity to be appreciable. In rendering respiration more active, the proportion of animal electricity is augmented. *It increases in a direct ratio with the activity of the circulation.*

Now may it not be concluded from these researches, that the dynamic-electric fluid, pro-

duced by the chemical phenomena of the circulation, is the source of sensibility, and that the nerves merely transmit the impression to the nervous centres? And does not this induction contain the phenomena observed in the autoplastic flaps! In fact, sensibility, though more feeble, exists in the flap until the pedicle is divided, after which it disappears completely, to be restored as soon as the circulation is re-produced in the flap, and its developement is in a direct ratio with the energy of the circulation. But how does the sensibility, developed by the phenomena of circulation transmit the impressions which are received to the brain. It will not be uninteresting to prove that this fact, however extraordinary it may appear at first sight, forms part of an ancient theory which obtained, about half a century ago, from the experiments performed by a member of the Academy, an authority which no one will gainsay.

The idea of an appreciable atmosphere surrounding the nerves and the muscles, was announced first at the school of Edinburgh, to the great scandal of the partizans of the Brunonian system, which was then predominant in Scotland. Taken up and developed by Reil, who formed from it a theory, it was finally established and demonstrated by the experiments of M. de Humboldt. In his admirable researches on galvanism, this eminent *savant* placed beyond a doubt the following facts; viz. that animal matter exercises an influence at a distance—that there emanates, from the nerves especially, a fluid appreciable to our instruments; that the distance at which this fluid acts is always in a direct ratio with the degree of vitality of the animal, and decreases in proportion to the time which has elapsed since death took place. M. de Humboldt while performing his experiments on hogs, perceived that the nervous atmosphere produced appreciable results at a line and a quarter from the divided extremity of the nerve, and that it persisted from five to eight minutes after death. These experimental facts lead us to conclude that in man in the plenitude of his vital power, the effects of the nervous atmosphere must be far more powerful and extensive.

M. de Humboldt has also demonstrated that the cellular tissue which forms the base of the cicatrix of the nerves, is a good conductor of the fluid just mentioned.

What therefore is wanting to explain the phenomena of transmission described in this memoir? I performed my operations on individuals endowed with energetic vital powers. The circulation of the nervous fluid interrupted by the operation, was restored by means of an intermediate conducting tissue, and the functions were re-established by the efforts made by nature—facts which cannot now be called in question. Thus the propositions which I have advanced may not only be considered as the rigorous deduction of the facts observed, but if I am not mistaken, they are in accordance with the best established physiological data.

It would be easy, in founding our opinions on those of MM. Serres, Velpeau, Lallemand, and Beclard, on embryogeny, and comparative anatomy, in taking advantage of the researches of micographs on the phenomena of capillary circulation, and the valuable lectures of Professor Dumas on the production of animal electricity, to show that nature, in restoring, as I have admitted, vitality and sensibility in autoplastic flaps, does not wander from the method it follows, to create and maintain sensibility in all organized beings. I merely point out this new subject to the attention of physiologists, my intention in this memoir, being only to submit to a rigorous analysis, and to verify by anatomical investigations, facts hitherto but little studied, and which may throw great light on various important physiological questions.

The Arctic Winter.—Five swans, of very small size and of [illegible] plumage, pronounced by Dr. Blasius to be the Arctic swans (called *Cygnus minor*), appeared near Brunswick. They were all taken, and sent to the ducal menagerie. This is the first time this swan has been seen in any part of Germany, and it is inferred that the winter must have been more than usually severe in the Arctic regions.

STATISTICS OF HERNIA.

By M. Maisonneuve.

M. Maisonneuve has made a statistical report of 11·644 cases of hernia, which were examined, during a period of six years, at the Central Bureau, Paris; he thus distributes them:—

Of 11.644 cases of abdominal hernia of every description,

8·790 were observed in males.
2·854 were observed in females.

Of 8·790 cases of hernia observed in males,

8·237 were inguinal hernia.
307 were crural hernia.
246 were umbilical hernia.

Of 2·854 cases observed in females,

1·112 were inguinal hernia.
639 were crural hernia.
560 were umbilical hernia.
543 were vaginal hernia.

Of 8·237 cases of inguinal hernia observed in males,

4·483 occurred on the right side
3·738 occurred on the left side.
16 not determined.

Of 1·112 cases of inguinal hernia in females,

542 occurred on the right side.
564 occurred on the left side.
6 not determined.

Of 307 cases of crural hernia observed in males,

171 occurred on the right side.
125 occurred on the left side.
11 not determined.

Of 639 cases of crural hernia observed in females,

344 occurred on the right side.
255 occurred on the left side.
40 not determined.

From these figures, Mons. Maisonneuve deduces the following corollaries:—

First. Herniæ in males are to herniæ in females, as 3 to 1.

Secondly. In 100 herniæ found in males.

93 were inguinal.
4 were crural.
3 were umbilical.

whilst, in 100 cases of hernia found in females, the proportion was

40 inguinal.
21 crural
20 umbilical
19 vaginal

Thirdly. In men, inguinal herniæ are met with as often on both sides as on one only, and in the latter case, those of the right side are to those of the left, in the proportion of 5 to 4.

But in women, inguinal herniæ are met with on both sides, three times out of four, and those of the right side are to those of the left, in the proportion of 5·42 to 5·64.

Fourthly. In men, crural herniæ are met with on one side only, three times out of four, and those of the right side are to those of the left, as 7 to 5; whilst in women, crural hernia are met with on one side only, 4 times out of 5; and those of the right side are to those of left, as 7 to 5.

Under the head, vaginal hernia, are included all tumours of the vagina and uterus presenting externally, and requiring the use of the pessary, as cystoceles, rectoceles, and prolapsus of the vagina and uterus.

Under the head, umbilical hernia, are included hernia of the linea alba, and displacements referrible to the neighbouring regions.—*Gazette des Hopitaux.*

De la Rue, Esq., W. Gregory, M.D., J. F. W. Johnston, Esq., M.A., R. Kane, M.D., W. B. Leeson, M.D., W. H. Pepys, Esq., R. Philips, Esq., J. D. Smith, Esq., J. Stenhouse, Ph. D., J. L. Wheeler, Esq.

PROGRESS OF FRENCH SCIENCE.

FROM OUR OWN CORRESPONDENT.

Paris, April 24th, 1845

*Luxation of the Elbow.**—J—ætat 24, joiner, while at work, the 25th March, 1845, on a ladder at about twelve feet from the ground, slipped, and his fall, rendered less dangerous by his being able to catch hold of the ladder at three feet from the earth, took place on the left side. Brought immediately to St. Louis, he was placed in the wards of Dr. Jobert de Lamballe, and when examined, the following symptoms were discovered; pain in the elbow; the fore-arm formed with the arm a very obtuse angle; position between pronation and supination; all motion, even that of rotation, impossible; the latter however could be performed by extraneous force; ecchymosis on the anterior and internal part of the fold of the arm; measured from the wrist to the epitrochlea, it was found to be an inch shorter than its fellow; circumference increased two inches; tendon of the triceps not very prominent; superior extremity of the olecranon on a level with the epitrochlea; veins of the fore-arm turgid; flexion and extension limited, but could be performed without much pain; bend of the arm swollen and presented a hard tumour; antero-posterior diameter taken opposite the most prominent part of the tumour an inch more than on the other side; the upper surface of the radius could readily be felt behind the humerus. The dislocation was reduced by gentle and steady traction on the fore-arm, and when the luxated parts were on a level with the normal position, by bending the limb suddenly. The reduction effected, the pain instantly ceased, the motions were restored, and all that remained was a hard swelling near the internal condyle of the humerus, with *engorgement* of the surrounding soft parts. No consecutive symptoms occurred, and the patient soon after left the hospital quite well.

Cancer of the Arm caused by a blister, amputation in the shoulder-joint; accident during the operation. Cure.—M. Deschamps, ætat 60; distiller; mother died at the age of twenty-four, of cancer of the uterus; father at that of seventy-nine, of paralysis of the bladder; no other member of his family had been affected with cancer; had never suffered but from rheumatism. After having tried various remedies during four years, for a rheumatic affection of the intestines, and obtaining no relief, a blister was applied on the arm. This was done twenty-six years ago; about fifteen years after its application, excrescences appeared around it, and in 1838, the arm became the seat of such severe shooting pains that the patient could not put on his coat. The disease increased in intensity, more so after he employed the paper prepared by Leperdriel to dress the blister with; suppuration very offensive and very abundant; tubercles developed on the circumference of the ulcer; notwithstanding this, the patient slept tolerably well and his digestion was not affected. About a year ago, Professor Velpeau who was consulted, cauterized the exuberant parts with the chloruret of zinc, Vienna paste, and nitrate of mercury. Dr. Jobert de Lamballe was afterwards called in; he examined the affected part, and was convinced that the only efficacious mode of obtaining relief was amputation of the limb above the seat of the disease, which was performed on the 6th November, 1844. Dupuytren's method,† modified

* Communicated by Dr. Morel Lavallée.

† The operation is performed as follows. "The arm being raised so as to form a right angle with the trunk, the heel of the blade of the knife must be placed below, and rather in front of the summit of the acromion, and all the parts forming the shoulder posteriorly, and the corresponding edge of the axilla, cut through with a firm hand. A first flap is thus formed, which, when raised, lays bare the hinder part of the articulation; the elbow is next carried forwards and on the head of the humerus, made thus to project backwards, the tendons and posterior portion of the capsule, are divided. The knife is then made to sweep round the head of the humerus from behind forwards, and the operation is terminated by an anterior flap, in which the

slightly however, was chosen by the skilful operator, pressure on the sub-clavian artery being effected by an assistant. The diseased limb was speedily removed, but before the axilary artery could be seized and tied, the patient gave a sudden movement, the assistant's finger slipped off the sub-clavian, and in a second Dr. Jobert de Lamballe found himself covered with blood. Aware of the danger, he, with admirable presence of mind, seized a sponge and coolly thrust it into the wound, thus compressing the divided artery, and giving his assistant time to renew the pressure on the subclavian. Had not this bold manœuvre been executed with promptitude and dexterity, the patient would have bled to death. The hæmorrhage having thus been arrested, the artery was tied and the wound dressed as usual. Two months after the wound was nearly healed, there remained a slight tumefaction just below the cicatrix, which was painful when touched; there were also a small excrescence in the centre of the wound, and another about the size of a nut at its anterior extremity. These two excrescences disappeared after having been touched with lunar caustic, and the parts gradually healed, leaving however, a small fistula, which slowly diminished, and the patient is now quite recovered.

On Accidents consecutive to Blenorrhagia.—Dr. Vidal de Cassis has, in several articles already published, proved the existence of prostatitis blenorrhagica, cystitis blenorrhagica, or inflammatory affections of parts which are in close connexion with the urethra in an anatomical or physiological point of view. But, organs which have but an indirect connexion with the urethra, may likewise be affected, of which the case about to be related is a proof. Here the influence of blenorrhagia cannot account for the development of the complications; for, it is from the contact of the blenorrhagic matter that ophthalmia is produced—this cannot be supposed to be the case when an articulation becomes affected. It is, therefore, far from being proved that the disease is caused by contagion—indeed the contrary opinion may be advanced, because ophthalmia appears in some persons, though they take the greatest care not to touch their eyes with the fingers soiled with the urethral discharge; and, because at the venereal hospital, individuals who are perfect strangers to cleanliness, are never affected with ophthalmia, (though they are affected with chancres or venereal buboes, suppurating freely), and finally because, since it is impossible to explain the development of arthritis, but by the metastasis of ancient and the sympathy of modern authors, it cannot be denied that ophthalmia may have a similar origin. *Case.*—Cheyne (George) ætat 24, tailor, middling height, weak constitution; frequently ailing, but never experienced any serious illness; has had measles, not variola, though not vaccinated; subject when a child to dyspnœa; 5 years ago was affected with itch, which yielded to sulphur baths; and 3 years after with gonorrhœa, which, after lasting three months, disappeared without his having taken any active remedies. Three weeks ago, he was affected with flowing from the urethra, pain and swelling of the meatus urinarius, followed by pain in the loins, especially on the left side, redness, pain and tumefaction of the left metatarso-phalangeal articulations, and finally pain in the eyes, though he had never touched these parts with his hand soiled with the blenorrhagic matter. These last symptoms prevented the patient from working, and consequently he entered the hospital on the 24th April, 1845. Examined the day after, he presented the following symptoms: muco-purulent discharge from the urethra; no pain, even when the parts were touched; very slight scalding at the meatus during the emission of urine, pain in the eyes, accompanied with vascular injection of the conjunctiva; slight photophobia; sero-mucous secretion perceptible, especially in the morning; cornea transparent; redness; pain and tumefaction of the left metatarso-phalangeal articulations; no general symptoms; appetite not very good. ℞ Nitr. argent. gr. i.; aq. rosæ, ℥j; collyrium sæpe utend.; pro potu. decoct. sarsapar. pil. perchlor. hydrarg. ij. 3rd May—pain in the right knee: slight fluctuation and tumefaction. 5th—left knee painful and slightly swollen; no fluctuation: tumefaction of all the phalangeal and tarso-metatarsal articulations. ℞ Extr. belladon. ʒj. ad ipis. ℥j. M. ft. unguentum, cujus pauxillum oculorum mane nocteque applicandum. Cataplas. emoll. sub ocul.—contin. collyr. et pil. &c. 8th—The fluctuation and the tumefaction of the knee increased. Emplas. canth. genu.—Contin. Medicam. 9th to 15th—cessation of the pain in the left knee; eyes in a better condition; discharge from the urethra diminished, whiter, fluid, blister caused great pain; now nearly dry. Contin. Medicam.—20th. The eyes, which hitherto had been improving, became suddenly worse, especially the right, where the secretion was purulent, though a purgative was administered; chemosis likewise supervened, and required cauterization with lunar caustic.—26th. Effusion in the cornea of a greenish yellow colour, similar to that of the discharge from the urethra at its commencement; this membrane is completely opaque, and somewhat elevated above the conjunctiva around it; surface dull, but not uneven; no vascular injection; complains of sore gums; omit pilul. et coll.; contin. potus, unguent &c. The amelioration from this period was constant, though slow; the only complication was a vegetation on the upper and external part of the eye, which having been removed and the little wound cauterized, did not re-appear, and the patient left the hospital, in the middle of June, quite well, with the exception of a slight opacity of the cornea, which disappeared by degrees, the part having been touched with a camel-hair brush dipped in laudanum.—*Annales de Chirurgie.*

Congestion of the Cerebellum.—Dr. C. Broussais, principal physician to the Military Hospital *de la Salpetriere*, at Algiers, has just published a case in which the patient lost his equilibrium whenever he stood erect or walked, and which, after passing in review the different diseases with which it might be confounded, such as affections of the cerebellum, the medulla spinalis, neurosis, &c., he attributed to a lesion of the cerebellum; because the section or cauterization of that portion of the nervous centres causes, as the experiments of Messrs. Flourens and Bouillaud on pigeons prove, a loss of equilibrium, the birds tottering like a drunken person, as the latter so aptly remarks; because in a case in which he had attended with Dr. Magendie, the patient offered all the symptoms observed in the present instance, and at the autopsy, the cause was found to be a cancer of the cerebellum. Finally as to the species of lesion, it was in all probability simple congestion, situated superficially, or in the membranes alone; may not these symptoms be explained by the difficulty with which the movements of the cerebro-spinal liquid are performed, owing to the congested state of the organ. It was for these reasons, that Dr. C. Broussais ordered venesection to be practised, and prescribed at the same time sulphas quininæ, as the patient was affected with intermittent fever. *Case*, G. ætat 27, soldier; went to Africa three years and a half ago, strong constitution; bilioso-sanguineous temperament; has since his arrival there, been affected with dysentery and intermittent fever; he suffers from tertian fever, and has already experienced two attacks. On his admission the 7th March, 1845, and while M. Dumalle was auscultating his thorax—he being seated in his bed—he suddenly fell backwards, senseless; this state however was of very short duration, and G. was soon able to give the details just stated, to which he added, that he could neither walk or stand erect for any length of time; no loss of sensibility nor motion; when requested to get up, he did so with perfect ease, but had hardly made two or three steps in the ward, ere his face became pale, his features contracted; he staggered and would have fallen had he not been supported. Taken back to bed, he was, after resting a while, made to sit up, but the same phenomenon took place as already mentioned; the heart presented nothing abnormal; pulsations beat 72 per minute; spleen not much enlarged; all the various functions appeared to be in their normal condition; from time to time the head became hotter than usual, as if the blood ascended in greater quantities. Venesectio ad lbj, sulphat. quin., ℈j. The next day being that on which the fever ought to have taken place, the quinine was repeated; it did not however come on, and nine days after, the patient left the hospital quite well.—*Gaz. des Hospitaux.*

Academy of Sciences. Sitting of the 21st April.—M. Elie de Beaumont in the Chair.—Received, Report of the British Association for the Advancement of Science for 1839 and 1843. M. Arago informed the Academy of the death of M. Th. de Saussure, who departed this life at Genoa, aged 77.

On the Chlorurets of Chrome, by M. H. Loewel, presented by Professor Dumas. From a series of experiments, the author concludes, 1° That the sesquioxyde of chrome combined with sulphuric, azotic, or chlorhydric acid, forms neutral salts, because an equivalent of the sesquioxyde is combined with three equivalents of acid. 2° That in the solutions of these salts, the sesquioxyde may exist under three different forms, giving to the liquid, a violet, violet blue, or bright red colour. 3° That besides these three, the sesqui-oxyde may undergo another modification, analogous to that presented by phosphoric acid, and by which its capacity for saturating acids is changed. In this case, salts are formed, whose solutions are green, and in which an equivalent of the sesquioxyde is combined with two equivalents of one of the above named acids. 4° That in the combination of an equivalent of the hydrated sesqui-oxyde of chrome with three equivalents of hydrochloric acid, the green solution does not contain a metallic chloruret, but a hydro-chlorate of sesqui-oxyde with three equivalents of acid, $Cr_2 O_3$ 3 Cl. H.; which corresponds to the neutral sulphate, $Cr_2 O_3$ 3 SO_3 and to the neutral azotate, $Cr_2 O_3$ 3 Az. O_5. 5° That on evaporating the green solution of hydro-chlorate of chrome, and keeping the residuum with certain precautions at a temperature of about 302° F. it loses an equivalent of its acid which is volatilized. The pale grey roseate powder thus obtained, soluble in water and giving a green solution, is not a chloruret of chrome, but a hydro-chlorate of the sesqui oxyde, in which an equivalent of the oxyde is combined with only two equivalents of the acid, $Cr_2 O_3$ 2 Cl. H., corresponding to the soluble sulphate of the sesqui-oxyde $Cr_2 O_3$ 2 SO_3 and the azotate $Cr_2 O_3$ 2 Az. O_5. 6° That the anhydrous salt is a grey roseate powder, when heated to a temperature about 572° F. in a closed vessel, is partly changed into an insoluble violet sesqui-chloruret, $Cr_2 Cl_3$ and is partly decomposed, a green sesqui-oxyde of chrome being formed, and hydrochloric acid disengaged. 7° That what proves that this powder is not a metallic chloruret, is, that if submitted in a closed vessel to a moderate, instead of a red heat, that is to say, somewhat lower than that necessary to convert it into a violet sesqui-chloruret, it is decomposed entirely into green sesqui-oxyde and hydrochloric acid, and only a very small quantity of sesqui-chloruret. 8° That the sesqui-chloruret of chrome cannot remain in solution as a metallic chloruret, but as a hydro-chlorate of the sesquioxyde, the water being decomposed by the proto-chloruret. 9° That probably the same result is obtained with the sesqui-chloruret of aluminium, iron, and the other metallic sesqui-chlorurets. 10° That the following re-action takes place when two equivalents of the proto-chloruret are added to an equivalent of the sesqui-chloruret; two equivalents of chrome of the proto-chloruret unite with three equivalents of oxygen, obtained from the decomposition of the water, to form one equivalent of sesqui-oxyde of chrome; the three equivalents of hydrogen combine with two equivalents of chlorine of the proto-chloruret, and one is lost by the sesqui-chloruret to form hydro-chloric acid, which unites with the sesqui-oxyde to produce the hydro-chlorate of the sesqui-oxyde of chrome, $Cr_2 O_3$ 3 Cl. H.

On the Composition of the Sesqui-chloruret of

artery is compressed, ere it is divided, "(Sabatier *Medecine Operatoire*, Ed. Sanson and Begin, 1832, vol. iv. p. 637) Cooper, speaking of this method, says:—"Dupuytren's plan would be difficult on the left side, unless the surgeon were ambidexter; but, in other respects, it cannot be found much fault with, and seems principally commendable on account of its celerity."—(Dict. of Pract. Surgery.)

Chrome, by M. E. Peligot. This substance, composed of three equivalents of chlorine and two of chrome, $Cl_3\ Cr_2$, is obtained in beautiful violet crystals, by causing chlorine gas to pass into a mixture of oxyde of chrome and charcoal at a high temperature; it is insoluble in hot or cold water, but is easily dissolved when a small quantity of protochloruret of chrome is added to the solution. From his experiments which were given in detail in the memoir—the author remarked that all the chlorine of the anhydrous or hydrated sesqui-chloruret is not precipitated, when an excess of a cold solution of azotate of silver is added; that this compound, when mixed with water, probably produces a hydrochlorate of the oxychloruret, the composition of which when crystallized may be represented by the formula, $2\ Cl.H.,\ Cr_2\ Cl.\ O_2\ 10\ H.O.$; that the compound $Cr_2\ Cl.\ O_2$ is decomposed by ebullition, and furnishes a limpid green solution from which hydrochloric acid may be separated by a solution of azotate of silver.

On Acute Delirum Observed in Establishments for Insane Persons, by Dr. Briere de Boismont.—This affection has hitherto been classed among cerebral diseases, or confounded with dementia. The symptoms are, however, very different: one of the most prominent is the dislike for liquids, sometimes carried to such a height, that the author has designated a variety under the denomination of *hydrophobic delirium*. Pathological anatomy generally reveals nothing, and when any lesion exists, it is owing to complications, not the primitive disease. It is to be distinguished from meningitis by the premonitory signs, the absence of cephalalgia, the nature of the aberrations of the mind, the disturbance of motion, the absence of vomiting, the dislike for all liquids; the spasmodic contraction of the œsophagus, extreme agitation, a discharge of purulent mucus from the eyes and nostrils; fœtidity of the excretions, and especially the absence of the anatomical lesions of meningitis. In acute dementia, and even mania, there is no fever, but the acts, gests and numerous characteristic marks of a maniacal type. Acute delirium ought to be considered as a nervous disorder, similar to that observed in drunkards, and after a serious operation; there is, in all probability, a cerebral modification, but of what kind it is impossible to say. The most efficacious remedy is a tepid bath, in which the patient should be kept for six, eight, ten, and even twelve hours, combined with shower baths, purgatives, and emetics; but emetics ought to be had recourse to with great circumspection.

On the Pathological Anatomy of Deafness, by M. Pappenheim.—Besides the lesions of the nerves the mucous and osseous tissues, the author remarked two phenomena, which he considers worthy of notice—the presence of cholesterine, consecutive to inflammation; it is to be found in the external ear, the tympanum, and even in the membranes of the labyrinth—the deposition of crystals of lime around the cells which the author discovered in 1837 in the membranous labyrinth, the deafness being more or less complete according to the quantity of carbonate present. The author likewise observed in examining the ears of deaf and dumb persons that inflammation of the external and middle ear was sometimes the unique cause of deafness in children, and consequent dumbness.

On the Phenomena Observed when Ascending Elevated Mountains, by M. de Pilcur.—It is well known that the symptoms generally observed are, acceleration of the pulse, anhelation, fatigue in the lower limbs, which soon disappears when the persons cease to ascend, whence the necessity of frequent stoppages; and according to the height or the idiosyncracy of the individual, anorexia, nausea, vomiting, in short, a state similar to seasickness. In this memoir the author relates day by day the different symptoms experienced by Messrs. Bravais, Martins, and himself, while ascending the Mont Blanc in 1844, and concludes, that some are owing to the elevated situation at which the observer finds himself, such as, acceleration of the pulse, loss of appetite, and, in some cases, somnolency; that others are produced by motion, combined with the former, such as, the peculiar fatigue experienced in certain muscles of the legs, dyspnœa, pulsation of the carotids, &c.

On Copper in the Normal Condition of the body.—M. Barse addressed a long letter, in which he maintains his opinion (affirmative) relative to the presence of copper in the normal state, and mentions, that having been requested to analyse with M. Devergie and Lesueur, the body of a man supposed to have been poisoned, copper was discovered; now, if it did not exist in the normal state, some person was guilty of a crime, and had the analysis been confided to a person professing that opinion, an innocent individual might have been condemned.

Academy of Medicine, Sitting of the 23rd of April. M. Caventou, in the chair.—The Prefect of the Seine requested the Academy to name a committee to enquire to what extent the administration of secale cornutum in midwifery cases may be productive of danger to the mother and child.

M. Segur Dupeyron addressed a letter, stating that he had erroneously mentioned the fact of the appearance of a case of plague on board a ship seventeen days after sailing, having ascertained, by subsequent researches, that it appeared on the seventh day.

The chairman drew by lots the names of the members to compose the deputation which is to wait on his Majesty on the 1st of May; they were M.M. Recamier, Dupuy, Moreau, Pattssier, Marjolin, Capuron, Cruveilheir, Jolly, Baudelocque, Reveillé-Parise, and Nacquart.

On the Health of the Workmen employed by Government in Tobacco Manufactories.—Report presented by Dr. Melier in his name, and in that of Dr. Loiseleur-Deslongchamps in reply to a document sent by the Minister of agriculture and commerce to the academy.—After a few remarks on the influence exercised by different professions, as yet so imperfectly known, notwithstanding the recent progress hygiene has made, Dr. Melier judiciously points out the difference of opinion which exists with respect to tobacco manufactories; thus Rammazini states that it is highly dangerous, whilst Parent Duchatelet, on the contrary, says that it is not the least injurious. Between these two opposite opinions, how is truth to be found? The mode in which the administration of the tobacco manufactory is carried on is so perfect, that it furnishes perhaps the most certain means of solving this interesting question. Not only is the culture of the plant, and the choice of the species submitted to rigorous scientific calculation, and the light furnished by experience, but likewise (according to the ground in which the plant grows) the number of leaves which ought to be left on the stem until maturity is designated. To give an idea of the manner in which this establishment is directed, it is sufficient to say that the individuals placed at its head are chosen from among the pupils of the polytechnic school, as is done for the *ponts-et-chausees*. Physicians are nominated to these manufactories; their duty being, not only to take care of the sick, but likewise to furnish annually in minute reports, all the remarks they may have made concerning the health of the workmen; the diseases observed in the manufactories, and the peculiarities these diseases may have presented; a very useful measure, and which shews the solicitude (too frequently forgotten) of the administration in behalf of the workmen confided to their superintendance, and which ought to be adopted by every establishment in which a number of workmen are employed. This would be the most efficient mode of collecting information as to the influence exercised by different professions, and would be useful not only to those who make hygiene their study, but even to the legislator.

The document sent to the academy is the recapitulation of the observations made by the physicians of the ten tobacco manufactories during the year 1842. It was drawn out by the desire of Count Simeon, *Directeur-General* of the Administration, who requested the academy to examine it. The subjects it treats of, are relative—1st, to the workshops, and the way in which they are kept—2nd, the diseases and accidents observed during the said year—3rd, the effects produced on the workmen. After taking a cursory view of the two first, the learned reporter examined the third with the attention it deserved. According to the document, tobacco produces little or no effect on the workmen. Two workshops alone, that in which the leaves destined to be made into snuff are allowed to ferment, and that where those with which tobacco for smoking is prepared are allowed to dry, seem to have an injurious effect.—Nay, more, it is supposed that the emanations from tobacco are a preservative against, or a remedy for, certain diseases, principally phthisis. These questions, especially, were of sufficient importance to draw the attention of the administration, and in order to solve them, Dr. Melier repeatedly visited the manufactory in Paris, which is the largest and most important. What follows is a brief summary of his laborious investigations.

Considered, with respect to hygiene, the workmen may be classed in different categories; according to the state of the plant, and especially as it is manipulated before or after its having been submitted to heat and allowed to ferment; two causes by which its activity is considerably developed. While on this subject, the reporter signalises the numerous ameliorations which have been adopted in the manufactory. The steam-engine having replaced in many parts manual labour, the workmen are thus enabled to avoid many accidents to which they were previously exposed. But notwithstanding these ameliorations, the manufactory of tobacco is far from being free from a deleterious action on the workmen, and indeed it is hardly possible to suppose that it could be otherwise, if we reflect on the composition of the plant and the energetic principle, *nicotine*, it contains—a principle which is a very violent poison. The effects produced, are: *primary*, such as cephalalgia, nausea, anorexia, insomnia, diarrhœa; symptoms which generally last for a week or two, and then disappear spontaneously—*consecutive*, characterized by a peculiar change in the colour of the skin, which assumes a grey tint. The latter is observed on very few workmen, and only after a considerable length of time, and in certain workshops, and is in all probability owing to a peculiar condition of the blood produced by the absorption of the active principle of the plant. The urine analysed by M. Felix Boudet was thought to contain nicotine.

But in recapitulating the effects of tobacco on the workmen—effects likewise observed on plants—the reporter added that they were far from being as serious as they were formerly supposed to be. All extremes ought to be avoided, and though manufacturing tobacco is not without action, still it is not so serious, as to be considered as very dangerous; it cannot be compared, for instance, to lead or mercury, for it does not produce like these metals violent colic, paralysis or tremors; it does not even give rise to any peculiar disease, but it causes certain physiological effects, such as may naturally be expected from the known proporties of the substance under consideration.

Is it true that in compensation for its injurious effects, it possesses some salutary ones? This is not at all improbable, for do not the greater part of our therapeutic agents owe to the same elements the salutary effects which cause them to be employed, and the toxic properties which render them formidable? It seems to be established beyond a doubt that the emanations from tobacco are sometimes useful. The workmen are so convinced of their efficacy in rheumatism, that if after taking cold, they are seized with rheumatic pains, they know of no better remedy than a long nap on a bed of tobacco leaves. In favour of this opinion, Dr. Melier quotes a series of cases, communicated by Dr. Berthelot, which proves that linseed poultices in which a decoction of tobacco is used instead of water, soon relieves the pain in rheumatism, and the cure on an average, is as prompt as with the other methods of treatment employed against this affection. Manipulation of the tobacco seems to be a preservation against intermittent fever, pests, and certain epidemics; for at Tonneins, the workmen were free from the sudor anglicus which reigned in the town. Ought it to be considered as a preservation against phthisis, and as a means of rendering its developement less rapid, and even of curing it? Though he considers those persons who drew attention to this circumstance worthy

of praise, since nothing ought to be neglected against so dreadful a disease, still Dr. M. does not think the opinion founded, as not only he did not witness any fact in its favour, but even witnessed some which proved the contrary.

The report closed with the following conclusions: —1° that the Academy after hearing the report on the document relative to the tobacco manufactories, approve the hygienic rules adopted, and the precautions taken in these establishments, to preserve as much as possible the health of the persons employed in them; 2° that the Academy especially approves the decision by which the physicians are requested to enter their remarks on a register *ad hoc*, and to make an annual report. 3° That the decision if observed will furnish the means of appreciating better than has hitherto been done, the real influence of tobacco on the health of the workmen, and be of use to hygiene and perhaps likewise to therapeutics. 4° That as to the opinions relative to phthisis and other diseases mentioned in the document, they can only, in the present state of medical knowledge, be considered as uncertain, and it is necessary that clinical observation should furnish conclusive facts, ere a decisive opinion be given. 5° That the Academy will receive with thanks any future information, and that it will examine it with the most scrupulous attention. This report, attentively listened to, was received with deserved general applause.—Dr. Villermé requested that the essay might be inserted in the memoirs of the academy, at the same time he made some remarks on the best temperature to which these workmen were subjected, and asked in what proportion were the men and the women in the manufactories. Dr. Melier in reply to the first question relative to the temperature, referred the speaker to his report, and as to the latter he stated that the females were in greater number.—Professor Moreau seconded Dr. Villermé's proposition, and asked what influence the tobacco emanations had on diseases of the skin, and if it cured the itch? Dr. Melier stated that no individual affected with that disorder was admitted into the manufactory, and as to its influence on cutaneous disorders he could but refer professor Moreau to his report. Dr. Villeneuve remarked that it was extraordinary that the amniotic liquid should have in the case mentioned in the report, given a strong smell of tobacco, whilst the urine analysed was not found to contain *nicotine*. Dr. Melier.—This fact is in a memoir published by Dr. Morizot, physician to the manufactory at Strasburgh. Dr. Gerardin.—Are all the manufactories furnished like Paris with steam engines, if not, it is easy to explain why opinions differ as to the amelioration of the health of the workmen since steam is employed, there can be no doubt, formerly diseases were far more serious and frequent, because the grinding the tobacco leaf is now done by the engine, and the emanations were more abundant during this operation than any other. The amount of wages also is an important feature, and was not mentioned in the report. Finally, Dr. G. coincides in opinion with the reporter as to the peculiar tint of the skin of the workmen which he considers to be a real cachexia. Dr. Segalas asked whether the influence of tobacco on the urine was on the quantity or the quality? M. Chevallier wished the phrase concerning Parent Duchatelet mitigated, for though perhaps mistaken on this point, still his works were deserving our attention; he likewise criticized the report in which it is stated that workmen get accustomed to thee dangers attendant on their trade; now this is not always the case; in lead manufactories, individuals have been remarked to have been affected fifteen times. Dr. Gaultier de Claubry stated that the emanations from tobacco are not a preservative from intermittent fever, for in 1830, this affection was prevalent in the manufactory in Paris, caused by a stagnant pool, and disappeared only when this was dried up. Dr. Castel attributes the abundance of urine observed, to the stimulating action of the plant; as to its curative properties in phthisis, it may be useful in asthenic or scrophulous phthisis, but it is evidently injurious when this affection is produced by irritation. Dr. Londe proposed adding a sixth conclusion—that notwithstanding the ameliorations lately adopted, the manufacturing tobacco is not free from an injurious effect on the workmen. Dr. Delens thought that a comparison ought to have been made between the therapeutic action of tobacco and that produced on the economy in the manufactories. Dr. Desportes attributes the discoloration of the skin to a disturbance in the functions of the liver, for having had an opportunity of performing a *post-mortem* examination, he found the liver diseased and the gall bladder containing little or no bile; he regrets likewise that the air of the manufactory has not been analysed, and that no hygienic rules were indicated. M. Chevallier points out the difficulty in obtaining the observation of the rules of hygiene by workmen. Dr. Rochoux mentioned that a distinction ought to be made between mineral and vegetable poisons, for the workmen never get accustomed to the former, and can do so to the latter: as to the cure of phthisis this is impossible, if by the word *cure* is understood the return of an organ to its normal state; none is ever seen in phthisis. Dr. Fontan remarked that no mention had been made of the gases which escape from tobacco; this gas is chiefly ammonia, a fact, which explains why the emanations are so useful in rheumatism, and why plants pine away and die. In the next sitting, Dr. Melier will reply to the various questions and objections.

GARLAND DE BEAUMONT, D.M.P.L., & S., &c
Honorary Physician to the Spanish Embassy

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN SCIENCE.

(The following comprise the principal articles of interest in the two last numbers of the *Lancet*.)

THE PROXIMATE CAUSE OF DIABETES MELLITUS.—Dr. Watts, in opposition to the opinion expressed by Dr. Prout, that the proximate cause of diabetes mellitus lies partly in the assimilating organs, and partly in the kidneys, advances the position, that the proximate cause of the disease lies in the organs of primary assimilation only, to the entire exclusion of the kidneys.* In reviewing the changes which the food undergoes during the process of digestion, he shows, on the authority of Prout and Liebig, that those articles to which chemists have given the name of the saccharine secondary principles, such as sugars, gums, and starch, undergo the following alterations during digestion in a healthy stomach:—They are converted into the oleaginous secondary principles, which, like the saccharine, have a composition destitute of nitrogen. A further change is then effected by their being animalized, or elevated into the azotized principles, without which their assimilation with the various tissues of the frame cannot be begun. If, from any cause, the digestion of the azotized or non-azotized matters be interrupted, the imperfectly assimilated aliment is either retained in the system, to be assimilated at some future time, or is excreted in certain forms from the various emunctories; and the form in which it is either retained or ejected, is determined by the stage in which its digestion has ceased. For instance, if the azotized class of aliment be imperfectly digested, they appear, both in the fæces and in the urine, in the shape of nitrogenized salts or acids. If the digestion of the non-azotized matters be incomplete, having ceased with the conversion of the saccharine secondary principles into the oleaginous, the latter are deposited in the cellular tissue in the shape of animal fat; and if the action of the stomach has ceased before their change into the oleaginous principles, they appear in the alvine dejections and urine, in the shape of diabetic sugar, or lactic or oxalic acid. Digestion is really checked in any one of these stages by disease; the appearance of azotised compounds in the urine being the usual result of an inflamed or febrile condition of the stomach, and the presence of the saccharine principles in the urine a consequence of an atonic condition of the organic nervous energy with which the stomach is supplied, not enabling it to do more than resolve them into a low sugar, &c., while, if the diseased condition of the stomach were such as to assimilate the saccharine principles with the oleaginous, but not to animalise the latter, it is owing to a state of nervous energy intermediate between that which is indicated by the azotised excretions, and that which is followed by the saccharine. These three conditions, indicated principally by the composition of the urine and fæces, are the consecutive stages of the disease, which may not proceed any further than its first and very frequent stage, in which the excess of animal matters is imperfectly digested, and in which the conversion of the non-azotised into the azotized is incomplete; or it may extend into the second, in which the animal matters are partially digested, and the saccharine and oleaginous principles are only converted into animal fat, and being deposited in that shape, causes great obesity; or, again, it may proceed regularly through these two stages into its third and last, in which it constitutes diabetes mellitus, and in which the saccharine principles are excreted as low sugar; or it may proceed at once from the first to the last stage, to the entire exclusion of the second, if the exciting causes of the last stage be applied in sufficient force, when the disease yet continues in the first; but it never reaches the last stage without going through the first, the prior existence of which is a *sine qua non* for the existence of the last. Four cases are narrated by Dr. Watts, in which the invasion of diabetes mellitus was preceded by inflammatory dyspepsia, the principal symptoms in each case being indicative of disease in the chylo-poietic viscera. With respect to the formation of fat, Dr. Watts adduces several examples to shew that it is owing to the farinaceous elements, when food is taken in excess above the wants of the system. Various causes, abstracted from different writers, are also mentioned, illustrative of its influence in disease, in seven of which the semiology clearly pointed to the production of disease in the chylo-poietic viscera. In the other thirteen no sufficient predisposing cause could be gleaned. In none of the twenty did the presence of fat in the excretions appear to have followed immediately on the action of any exciting cause, the diseased action appearing in each instance to have had a long previous existence. The termination was fatal in two cases, the others either recovering, or at all events being alive at the date of the report. Of the ten fatal cases, five were found to have organic disease of some of the chylo-poietic viscera, especially of the pancreas; three are said to have died much emaciated; and two died of phthisis. Five of the remaining cases still exhibited evidences of existing disease, a perfect recovery taking place in five cases only. In two, the fatty discharge was connected with diabetes mellitus, preceding and ceasing on the excretion of saccharine urine in one instance, while the two were concurrent in the other. The connexion between unwonted formation of fat, and the consequent corpulency, with subsequent diabetes mellitus, Dr. Watts considers is shown by cases published by Dr. Prout in his work "On Stomach and Urinary Diseases," and by others published by Dr. Bright, Dr. Elliotson, Dr. Keith Imray, Mr. Jones of Jersey,* and himself. He (Dr. Watts) says, that in the eleven cases to which allusion is made, there are seen in very intimate connexion, the formation of fat, and of sugar in the digestive organs, and when it is considered that each of these states requires previous disorder of the function of digestion, and that in comparative health obesity requires for its production an excess of the saccharine principles in the diet; and as the conversion of the saccharine secondary principles into the oleaginous takes place in the stomach, he thinks he is warranted in holding the opinion that the deposition of fat, either in the cellular tissue of the body, or its excretion, is dependant upon the existence of the same causes which, when they proceed further, are followed by the existence of sugar in the urine;—in other words, that obesity, or the excretion of fat, is legitimately entitled to be viewed as a prior stage of those diseased actions which naturally end in diabetes mellitus. The presence of sugar in the urine is referred by Dr. Watts to either an altered or atonic condition of the nervous influence of the stomach, or one perverted from its natural state.

* Published in the last vol. of the *Medical Times*

POLYPUS UTERI.—A case of this disease is reported from the practice of Mr. Sands Cox, at the Queen's Hospital, which was successfully treated by the application of a ligature made of common unbleached whipcord, as recommended by Mr. Waine, on account of its increasing in thickness, and diminishing in length when moistened; so that instead of becoming loose after its application, it gradually increases the power of its grasp on the tumour

PERFORATION OF THE INTESTINE.—Mr. Linnecar, at a meeting of the Medical Society of London, narrated the case of a gentleman, a free whiskey drinker, who, after having suffered for ten years from occasional attacks of uneasiness about the epigastrium, accompanied by vomiting, was suddenly seized with acute abdominal pains, followed by intense collapse, and death in eleven hours. On examining the body, there were marks of chronic, and also of recent peritonitis, and there were six or seven portions of the jejunum and part of the ileum inflamed, and so constricted, that they would scarcely admit the passage of an ordinary goosequill. One of these portions was perforated. The liver was tinged of a deep melanotic colour, for an inch from its surface. The case was peculiar from the little suffering experienced by the patient, and the absence of the more prominent symptoms.

FUNCTIONAL APHONIA.—Mr. Bishop, at a meeting of the Medical Society of London, read a paper on functional aphonia He considers that the loss of voice, when it is purely of a functional character, generally arises from a relaxed condition of the soft parts, which form the boundaries of the vocal tube. He directed the attention of the members to the acoustic influence of a membranous pipe when adjusted to a reed, the walls of which, when relaxed by moisture, will extinguish the sounds of the reed, and he considered the vocal cords to be influenced in the same manner. He is of opinion, that when aphonia arises from a relaxed state of the pharynx in delicate females, the malady is of an asthenic character, and, consequently, an antiphlogistic treatment, with counter-irritants, rather does harm than good. He mentioned several cases in which the voice had been preserved by the application of a strong solution of nitrate of silver to the fauces by means of a camel's-hair brush, also by the use of gargles of capsicum; but he much prefers the argentum nitratum. He also made some observations on hysteric aphonia, and aphonia produced by sudden surprise. He believes that a partial relaxation tends merely to deepen the tones of the voice, without extinguishing it altogether, and drew attention, among other cases, to that of Grassini, whose voice, when in England, sunk an octave, from a relaxed condition of the vocal tube, and on her return to Italy, resumed its original character. In her case the voice oscillated between a soprano and contralto.

CALCULUS IN THE URETHRA.—A case is related from the Royal Free Hospital, of a child labouring under calculus in the bladder, which made its way into the urethra, causing obstruction to the passage of the urine, and rupturing the canal. The calculus was ultimately extracted, but a fistulous opening remained in the canal.

SOLUBILITY OF THE EXTRACT OF CANNABIS INDICA.—Dr. Inglis says, as the pure extract is abundantly soluble in the essential oils, they may be used to form elegant vehicles for the exhibition of the gunjah. Solutions are produced of a bright emerald green colour, which, partaking of the soothing sedative properties of the gunjah, do not possess so powerfully its death-like depressing effects, which, for the time, are so alarming to the patient. They may be made of such strength, that a quarter of a grain of the extract may be exhibited in two drops of oil, which may then be rubbed up with a little sugar, and made into a draught by the addition of hot water. He has frequently given the gunjah internally, in a similar manner, in combination with cajeput oil, in which it is particularly soluble, and he has found that it may be used as a valuable embrocation, in chronic rheumatic affections of the joints.

ON GENERATION.

By JAMES ANDERSON, Esq. Leicester.

The learn'd is happy, nature to explore,
The fool is happy that he knows no more.

Mr. Blaine says, impregnation is brought about by means of the action of the semen on the ovum, or germ, but, whether the effect is produced by actual contact, or by sympathetic influence, the most arduous investigations have not yet fully informed us, although the balance is, by direct experiment, very much in favour of the actual transmission of the impregnating fluid through the uterus and ovarium. Haller, Verheyneus, Ruysch, Hunter, Dr. Haighton, and Mr. Cruickshanks, advocate the doctrine that the semen is not arrested within the vagina, but is carried into the uterus and ovary. Other eminent physiologists however are of opinion, that impregnation is not the effect of immediate contact, but of a subtle exhalation from it, termed aura seminalis, that the uterus might receive the substance of the semen by absorption; indeed it has been stated by some that impregnation is always the consequence of venous absorption of the semen from the uterus, which thus acts on the ovaria through the medium of the circulation. As to the latter theory, the experiments of Spallanzani are conclusive in proving the negative, there is additional evidence from the fact, nothing that has the least token of life being discovered by the best glasses, either in the blood, saliva, urine, bile, or chyle;—what could then become of the animalculæ, peculiar to the semen, without which no impregnation can take place? Leeuwenhoek states that animalculæ are found in the semen masculinum of every animal, their general appearance is very much the same, nor does their size differ in proportion to the bulk of the animal, and they resemble tadpoles. He placed a hair of his head near them, which hair, through his microscope, appeared an inch in breadth; at least sixty such animalcules could lie within its diameter, and 216,000 of them are but equal to a globe, whose diameter is the breadth of a hair. Their figure is different from that of those found in any other fluid, and he believed them to be the rudiments of future animals, and thought them to be of different sexes, and upon which depended the future sex in the fœtus. It is a general law, that living beings derive their origin from pre-existing living beings. We can scarcely refuse our assent to the position, that these animalcules are in some way or other instrumental in the production of the fœtus.—*Dr. Bostock.*

M. Buffon contends that spermatic animals are not creatures really endowed with life, but something proper to compose a living creature; and he distinguishes them by the name of organic particles. The same individual kinds of animals he declares he has found in the fluids separated from the ovaria of females.

That the seminal animalcules are the proper rudiments of the fœtus, and are, perhaps, of different sexes, and in case of impregnation one of them is carried not only to, but into a vesicle of an ovary which is in a condition to receive, and be duly affected by it. It is admitted on all hands, that the seminal animalculæ are essential to impregnation, "since they cannot be detected where either from age or disease, the animal is rendered sterile."—*Dr. Knowlton.*

We are aware eminent anatomists assert, they have found semen in the Fallopian tubes; may they not have mistaken the semen for the natural secretions? it is admitted that the semen may occasionally enter into the uterus.

The component parts of the semen by analysis.

Water	90
Animal mucilage	6
Phosphate of lime	3
Soda	1
	100

When experiments are made on animals after copulation, the contents of the uterus and Fallopian tubes might be compared separately with the above analysis, or brought under microscopic examination, *vide* a trial in Edinburgh reported in the MEDICAL TIMES, vol. x. page 60, which will assist in settling this most intricate point in physiology.

Conception seems to depend upon the influence of the semen exerted on the ovaria, through the medium of the rest of the genital system; for women have conceived when semen has been applied merely to the vulva, the hymen being entire.—*Dr. Burns.*

Conception has taken place where the vagina terminated in the rectum, and where it was so contracted by a cicatrix as not to admit the penis. In 1828, I had a patient, a lady, who had borne a large family, after her last confinement, adhesive inflammation took place, and the vulva became so much contracted, that nothing larger than the size of a goose quill could be introduced, notwithstanding which she became pregnant.

Harvey and De Graef dissected animals at almost every period after coition, for the express purpose of discovering the semen, but were never able to detect the smallest vestige of it in the uterus, in any one instance.

As soon as impregnation takes place, the os uteri closes, and becomes impervious to the semen ejected in subsequent acts of coition; this alone goes far to bar superfœtation, yet many instances are on record that from two to seven children have been brought forth at one birth, from three months to the full time. That could not have taken place through the medium of the uterus in the gravid state, and under such circumstances the most natural inference is that the semen was conveyed to the ovarium from the vagina in some other way than the uterus. Mr. Madden observes, what is vulgarly called sympathy and antipathy is nothing less than animal magnetism In Glanvil's Saducismus Triumphatus it is said "nature acts on the human body by subtle vapours and upon heaps of minute particles, which pass from one body to the other."

That there is a set of absorbent vessels leading directly from the inner surface of the labia externa and the vagina to the ovaries, the whole office of which vessels is to absorb the semen and convey it to the ovaries.—*Dr. Dewees.*

Dr. Gartner, of Copenhagen it is said, has discovered a duct, leading from the ovary to the vagina; admitting that to be the fact, yet others are wanting, viz, from the ovaria to the breast or how shall we able to explain the following most extraordinary medical case as reported in the Hanau Gazette, 1838, as having recently occurred at Berlin, where a Polish countess, who, ever since the death of her husband, experienced frequent pains in the chest, was put under the care of Dr Von Graefe, by whom it was decided that amputation of one of the breasts was necessary The operation was performed, when there was discovered in the breast, a perfectly formed fœtus of several months!!!

We need not multiply contradictory opinions, when it is said that there have been two hundred and sixty hypotheses on this subject. With great deference to the authors mentioned in this paper, we are rather inclined to believe, that no actual transmission of the semen passes through the uterus and oviducts to the ovarium, or of aura seminalis through the uterus, but by direct absorption from the vagina to the ovaries: and that the animalculæ in the semen are the beginnings of future animals.

At a late meeting of the Chemical Society a memoir by Dr. J. Blyth and Dr. A. W. Hoffmann, entitled "On styrole, and some of the products of its decomposition," was read. Styrole is a volatile oil, obtained by distilling the balsam styrax or storax, although only in small quantity, and has a general analogy to benzin. In one property styrole is, perhaps, the most extraordinary of substances: a limpid fluid at ordinary temperatures, it becomes a transparent colourless glass when heated up to a certain point, and remains so when it becomes cool—a circumstance which will draw the attention of optical inquirers to styrole. In distilling storax to obtain this liquid, twenty parts of storax are mixed with seven parts of carbonate of soda, and water put into the retort. In one experiment, forty-one pounds of balsam yielded twelve ounces of styrole; in another, twenty-seven pounds yielded three ounces. The fresher and softer the storax, the more productive is it of styrole.

NOTICE TO CORRESPONDENTS.

Dr. Sharrin.—*We shall suspend judgment till the two statements are before us.*

The article on Mines *would be more valuable to us if the original and fuller MS. were sent to us.*

Young Student.—*Quain and Sharpey's Anatomy, the work of Chelius on Surgery (now being issued in parts by Renshaw, edited by Mr. South), and Copland's Dictionary of Medicine—published by Longman and Co.*

A Two Years' Subscriber.—*The M.R.C.S. and the L.A.C., or a gentleman who is either, can register as a General Practitioner by the new bill. The bill, also, is to be altered, so that the present M.R.C.S. can register as* "Surgeon," *if he prefer that title, singly, to the one indicating general practice. The L.A.C. may not register as a Surgeon, though he may as a Licentiate of Surgery.*

A. W.—*Gentlemen may register by any one of the titles they possess, according to their own will, and may practise in any way they please, notwithstanding the title by which they may be registered. No double registration will be allowed.*

Medicus.—*The information asked will most probably be forwarded privately, the note having been placed in proper hands. Any communication on the subject should be brief.*

Mr. Armstrong *will oblige us by sending the whole of his MS.*

Dr. Roden's *letter shall appear next week.*

Medicus.—*Licentiates of the Hall will register as Licentiates of Medicine and Surgery by the new bill.*

L.A.C. *was refused most improperly the discharge of the duty of examining the body. By study, by position, and by legal right, L.A.C. had the title impugned by the coroner.*

Mr. Stopford Taylor and the Chester trial.—*We have maturely considered the whole of this case, and in the absence of any well authenticated report by a gentleman at all conversant with the subjects discussed or examined, we cannot but conclude that, amid the conflicting opinions and narratives given, no condemnatory observations on the character of a professional brother can be justified.*

M. B. *will find all he he desires in the Pharmaceutical numbers of the* Medical Times, *twelve of which have been published.*

A. B., a Subscriber.—1. *Sir James Graham has by letter declared that Physicians may register as General Practitioners.* 2. *The worth of a foreign diploma will depend on the decision of the Council of Health. It will most probably, when* properly *obtained, be allowed—and disallowed in all other cases. If not allowed, the possessor, so far, will be as without any diploma.*

To Medical Students.—J. S., a poor Student, &c.—*The bill's retrospective tendency in reference to students has not been referred to by Sir James Graham in his new alterations. It is therefore urgent that medical students should bestir themselves to get inserted a clause, by which those examinations and that future position may be secured them which were held out to them at the time of commencing their studies.*

Dr. Black *writes to us to say, that the Glasgow Faculty to be annihilated by Sir James Graham is a very insignificant body. "The Faculty" in the Glasgow district only comprehends sixty, while the* non-entrants *amount to more than 300 practitioners. The members, also, have not increased during the past year. He anticipates great advantage from this supercession of the Faculty.*

T. W.—*A few numbers back we gave the composition of the black soap named by Dr. Sutro as useful in paralysis.*

We are this week, much to our regret, precluded the insertion of two very valuable original papers from the eminent pens of Dr. Clay and Professor Piorry. The encroachments made on our space by medico-political matter is, of course, the cause.

"A Subscriber and Constant Reader" *suggests that if the Fellows who object to the new Charter would conjointly send back their new* honour, *with contumely, to the Council, they would show a praiseworthy* esprit-du-corps, *and would produce a proper impression on that refractory board of mismanagement.*

THE MEDICAL TIMES.

SATURDAY, MAY 10TH, 1845.

"Union is strength."

The meeting of Tuesday evening will mark an epoch in medical annals. It is a rich earnest of an affluence of good to the Profession. In its issues the mental eye saw, visibly, not the promise—not even the advent—but the actual presence of immense amelioration. THE MEETING HAS CARRIED THE GRANT OF A ***NEW AND INDEPENDANT*** INCORPORATION.

There was dissension, noise, and ill-blood, it is true—but they were not *of* the meeting, but *at* it. It was the dissension, noise, and ill-blood of what Mr. Hillier's conclusive authority proclaimed a "faction;" of a few miserable malecontents—whose tempestuous assaults and successless disturbances achieved the unmeant good of showing how firmly the Association is established in the convictions and affections of the Profession. Drawing a veil, however, over errors which have about them, as appeals to our pity, all the perverse wildness of utter irresponsibility, let us mark, with pleased commendation and glowing thanks, the parts so gracefully played by Messrs. Hillier, Webster, and Cooper. Charming to our ears was Mr. Hillier's acknowledgment that the Committee deserved well of the public, and that no "faction" should further seduce him to oppose their proceedings; and more than pleasing—delightful were the eloquent words of Dr. Webster, repelling from the members of the Committee every accusation that spleen had created, and holding them forth as the intrepid assertors of a cause that they would yet force to triumph. That one address dissipated a world of unmeaning prejudices, and well repaid us the insensate disturbances that invoked it. In the all-absorbing interests that at this critical moment exist for universal harmony, it is indeed gratifying to note down circumstances so symptomatic of the helplessness of all mercenary plottings after division. Yes—if union is essential to the amelioration within our grasp, union, fortunately, despite the worst that can be done, will not be wanting.

"Finis coronat opus."

THE outline of Sir James Graham's Bill, in what may be considered its *final* form, is before the country by the speech we this day publish. There are, doubtless, some very material alterations; some of which the profession will hail with great satisfaction, but on the whole, it is not *all* we expected. It contains too much of the old leaven of the Corporations: too little of the new leaven of Sir James Graham. The ill-advisings which vitiated his first scheme and subsequent remodelling, has been active enough to cut off many a perfection from the bill we now get. But there are improvements, and while acknowledging them, let us touch on them, *en passant.*

The feature of paramount interest is, of course, the concession of the New Incorporation. We will not disguise our belief that on every principle supposed for years to be identified with the cause of Medical Reform, this must, with so refractory a body as the College of Surgeons, be regarded as a gigantic step in the right direction. The General Practitioners are given the self-government they have so long asked. Forming, as we and they have maintained, *the* profession, they shall no longer, says Sir James, be serfs to the dominant hierarchies of two alien Corporations, but shall manage their own affairs, use themselves the monies they contribute, appoint the officers they pay, and, in fact, hold their own fates to a very considerable degree in their own hands. The Council of the Colleges and their Fellows have had their claims to superior distinction challenged, doubted, denied. Our New Incorporation will afford us the opportunity of establishing the truth of our defiances, and of making clear to the world the equality we claim. In one sentence, we are taken at our word, and given an occasion to prove that we are all we professed to be.

So far, so good. If our brethren hold true to themselves, if they run counter to none of their pledges of undying hostility to the College that, Judas-like, misapplied their money, and with the words of peace betrayed them, there can be no doubt that the interests of science will be largely promoted, and the dignity of the profession prodigiously elevated by the erection of the New College. Good Government is at the root of nine-tenths of the victories of science, and it would be odd if that body, which, despite all the disadvantages of every possible bad system, has upheaved in social respectability, and professional worth, should sink, when conceded, those boons whose absence had retarded so considerably their uprise, and when to the temptation to labour of sure honours to shewn merit, is added the stimulating rivalry between three opposing corporations.

But the third estate, though granted to us in no unkindly spirit, is not granted, we grieve to say, in all its fulness—handsomely and confidingly. There is a damning spot thrown on the escutcheon of the new college by the joint body of M.D.'s and surgeons, formed to examine who shall, and who shall not, be admitted to a college that belongs to their rivals. We find here again the hand of Sir Benjamin Brodie at least as bad at legislation as he is good in surgery. His paternity in the new college is the last thing to be desiderated; and an arrangement like this—conceived in iniquity, and born in sin—would form the original stain of the new-born institution; a stain which, ineffaceable by no baptism save that of Parliament, would condemn the sufferer to a miserable and worthless existence. But perhaps we misunderstand Sir James.

We should reserve judgment till the bill itself is before us. It cannot be with the good sense he really possesses, and the anxiety for conciliation that he lavishly exhibits, that he deliberately thinks of transferring the functions of the new College to its jealous rivals. The initiatory rites of the profession should surely be solemnized by those whose ministry it is to have charge of what Sir James calls the "portal" of the profession. The postulant is admitted, not to the penetralia of the Surgeons or the Physicians. That is a matter that may perchance follow, but after a long interval, and *then* it may well be made the duty of the Surgeons and Physicians to take charge of the candidate. But as they will not admit the new College's interference then—theirs should not be permitted before. Besides, why all this mysterious supernumerary legerdemain, by which the poor candidate is made the victim of College expenditure, as the traveller in Germany of passport dues? He is sent where he has no business, and whence he can derive no service, for no purpose we can see, save to pay taxes. First, a court of twelve physicians and pure surgeons tax him for thinking about the professional journey; then he is taxed by the general practitioners; then he is taxed

probably by one of the universities; then he is taxed by the surgeons; then by the physicians; and again, he is taxed and taxed as often as he roams from Scotland to Ireland, or Ireland to England, and so on for ever!

But, as we said, there must be some mistake here, and we earnestly urge on the Committee of the National Association to see that it is a mistake. They cannot be too speedy. The bill is not *yet* printed. Such a mistake would be fatal to the independence of the New College. It would make the Charter not worth acceptance. Nay, further, it would create the duty of not accepting the Charter. The Association is at this moment a College, one which a *defective* Charter would strip of more power than it could confer. Recognised or not by the Government, it will equally *rule* the profession, and it must not forfeit its high position without a suitable consideration.

Deferring further remarks till able to give the Bill, as we hope in our next number, we cannot forbear our acknowledgments for the direct recognition, by statutory enactment, of two General Practitioners on the Council of Health, and the complete omission of the clause interfering with the public's discretion in the appointment of its medical attendants. These are certainly very considerable improvements. Taking these in connexion with the proposed change about University "Inceptors" and the establishment of the New Incorporation, we cannot hesitate to express our opinion that the Bill will meet with a far more favourable reception than in any of its previous phases.

NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY*.

A general public meeting of the members of this association was held on Tuesday evening last, at 6 P.M., at the Hanover Square Rooms, to receive and adopt the report of the committee, and to transact important business connected therewith. The meeting, which was summoned by public advertisement, and by private circular, consisted of little more than four hundred gentlemen when the chair was taken at a quarter past six, but the room soon afterwards began to fill, and before the reading of the report was concluded, the assembly numbered upwards of one thousand. Among the gentlemen present, we noticed Mr. Pennington, the president, Mr. Hawes, M.P., Mr. Nussey, Mr. Moore, Mr. Squibb, Mr. Barnes, Mr. Randall, Mr. Morrah, Mr. Headland, Mr. Bird, Mr. Ancell, Mr. Streeter, Mr. Merriman, Dr. Webster, Mr. Propert, Mr. Clifton, Mr. Fuller, Mr. Bowling, Dr. Cooke, Mr. Vickers, Mr. Hillier, Mr. Wakley, &c.

Among the country members present, were Mr. Tyte, of Harrow, Mr. Snowden, of Ramsgate, Mr. Mackinlay, of Isleworth, Mr. Martin, of Reigate, Mr. Harris, of Worthing, Mr. Flower, of Chilcompton, Somerset, Mr. Holmes, of Fulham, Mr. Sanders, of Maidstone, Mr. Oliver, of Stilton, Mr. Bonney, of Brentford, Mr. Page, of Newmarket, Mr. Hawkins, of Bristol, Mr. Scott, of Bromley, Mr. Morgan, of Devynnock, Brecon, Mr. Turner, of Wycombe, Bucks, Mr. Callen, of Sheerness, Mr. Beavan, of Rochester, Mr. Wooldridge, of Southampton, Mr. Garthron, of Norwich, Mr. Sanders, of Gravesend, Mr. Phillott, of Mortlake, Mr. Chambers, of Hopton, Suffolk, Mr. Bond, of Nuneaton, Warwickshire, Mr. Thornton, of Uxbridge, Mr. Thompson, of Westerham, Kent, Mr. Gabb, of Charlton Kings, Cheltenham, Mr. Beancraft, of Barnstaple, Devon, Mr. Halford, of Hammersmith, Mr. Dalton, of Hammersmith, Mr. J. Brown, of Hammersmith, Mr. A. Foote, of Kew, Mr. Abercrombie, of Ealing, Mr. Camden, of Hounslow, Mr. Jones, of Blandford, Dorset, Mr. Bottomley, of Croydon, Mr. Wildash, Wye, Kent, Mr. Martin, of Horsham, Mr. Gern, of Ross, Hereford, Mr. Leney, of Maidstone, Mr. Warner, of Cirencester, Mr. Daniel, of Ramsgate, Mr. Jones, of Ross, Herefordshire, Mr. Burrows, of Brighton, and Mr. Parkinson, of Penkridge, Ware, Herts; several of these were honorary local secretaries in their respective districts, and were present, as representing the branch association with which they were connected.

Mr. Nussey moved, and Mr. Propert seconded the resolution, that Mr. Pennington be requested to take the chair.

The resolution was carried unanimously.

Mr. Pennington, on taking the chair, observed, that as there was much important business to occupy their attention that evening, he would only detain them to say how deeply he was obliged by the kind manner in which they had expressed their wish that he should preside on this occasion. He accepted that honour with the greater satisfaction, as he believed that the report which would be presented to them from their committee, would convince them that no efforts had been spared to secure the attainment of the objects for which the association had been called into existence, and would also prove that there was every probability that those objects would be speedily obtained.

The minutes of the last general meeting were then read by Mr. Bird, after which, Mr. Ancell read the report of the committee to the following effect:—

REPORT.

The Committee have deemed it expedient to call a Special General Meeting of the National Association, that they might have the honour of laying before the members of the association a report of their proceedings to the present date.

One of the first acts of the committee after the public meeting held on the 14th day of March last, was to forward to the council of the Royal College of Surgeons, the fifth resolution passed at that meeting, condemnatory of the policy of the council, together with a letter, dated March 20th, and addressed to the president, vice-presidents and council of the college. In consequence of Sir James Graham having declared, in the conference with a deputation from the committee at the home office, on the 14th February last, that the chief obstacle which presented itself to his granting a charter of incorporation to the general practitioners, was his disinclination to separate them from the college of surgeons, and in deference to the wish so strongly expressed by the right honourable gentleman, in his speech in the House of Commons on the 23d of February, that a reconciliation should take place between the general practitioners and the council of the college of surgeons, your committee took upon themselves the responsibility of so framing the letter above referred to, as to shew every inclination on their part to confer with the council, and to prepare the way for the reconciliation suggested from so high a quarter. The letter of the committee, and the reply of the council, dated April 3d, which reply is essentially a manifesto repudiating such of the members of the college of surgeons as are general practitioners, were forwarded without delay to the government, to the Society of Apothecaries, and to the Press, and, by the published transactions of the committee, to every member of the association.

The Committee request the attention of the meeting to the circumstance, that throughout the period of the organization of the National Association, the members of the Royal College of Surgeons who joined it have also pursued, totally irrespective of the association, their own independent course as relates to the college—whether by remonstrating with its council—by memoralizing the Government, or by petitioning Parliament—a course by no means inconsistent with their adhesion to the association. Had these efforts been successful in effecting a change in the constitution of the College of Surgeons, so as to render it a College of General Practitioners, the committee again repeat, that a "New Incorporation" would be unnecessary. All the efforts, however, made for this purpose, by the members of the college, whether members of this association or not, have proved unavailing. Every act of the council of the Institution has brought into broad relief its fixed determination to maintain it as a *College of pure Surgeons*, and although the Right Hon. the Secretary of State has uniformly expressed his regret, that any separation should take place, he has given no encouragement to expect, that either by the authority of the Crown, or by parliamentary enactment, Government would interfere for the purpose of changing the avowed policy of the council. The committee have accordingly used their best exertions to fulfil their duty by pursuing, without intermission, the original object for which the association was formed.

They may be allowed upon the present occasion to remind the meeting that the association was called into existence for the specific purpose of obtaining a charter of incorporation for the general practitioners, and of forming an independent college, under the sanction of an Act of Parliament. This object is explicitly set forth, not only in the published documents of the association, but in the greater number of the communications with which the committee have been honoured, from the general practitioners in the country. A considerable portion of the members of the association abstained from joining it until they had individually satisfied themselves of the necessity of such new *Incorporation*, and they have expressed themselves to this effect in their letters to the committee. It will thus be perceived, that whatever collateral measures the committee may have deemed it expedient to adopt, they were bound neither to omit, nor to procrastinate any step, which, in their judgment, was calculated to promote the views of their constituents, and to secure the one great object of the General Practitioners of the Kingdom.

Whatever regret a considerable portion of the members of the National Association may feel, at the course pursued by the council of the college of surgeons, the committee have the satisfaction in reporting there is now every reason to believe the government to be convinced, that a New Charter for the General Practitioners is essentially necessary for the interests both of the profession and of the public; and that from the representations which have been uniformly made, both by the society of apothecaries and the national association, to the government, and from the anxious desire expressed by the Right Honourable Sir James Graham, to maintain the respectability of the general practitioners as a class,—your committee have the greatest confidence, not only that a charter will be granted, but that it will be of such a nature as to be acceptable to the great body of general practitioners in this kingdom, and amply to secure their interests in the projected legislative arrangements of the profession.

The conferences which have taken place between the Society of Apothecaries and the National Association, to the 4th of April inclusive, have been printed and circulated among the members of the association. It is a subject of the greatest congratulation, that no important points of difference now exist between the two bodies. The executive of the Society has been placed under the most favourable circumstances, to arrive at a thorough acquaintance with the real interests of the general practitioners. Liberality, consistency, and firmness, have characterized all their proceedings. The deliberations between the court of assistants, and the committee of the association, have been conducted with the strictest mutual confidence, and the two bodies are placed in the most favourable position to act in conjunction on the part of the general practitioners of the kingdom, in those negociations with the Government which have now become necessary.

The committee, in the next place, beg to call the attention of the meeting to the following important transactions. On the 14th of April, the Honorary Secretaries forwarded to the Society of Apothecaries the following documents:—

First.—The amended Suggestions for Heads

* A meeting, called by advertisement, was held the previous night, by what Mr. Hillier calls the faction, at the Freemasons' Tavern. Only seventeen gentlemen were present, of these, several, including Mr. Hillier, protested against prolonging the opposition, as injurious to the best interests of the profession. Mr. Wakley, however, persisted, with what result, the report of this meeting will show.

of Charter, mutually agreed upon at an adjourned conference, held on Friday, the 11th of April, by the committee of the court of assistants of the Society of Apothecaries, and a deputation from the committee of the National Association, and which suggestions for heads of charter, as amended, were confirmed unanimously by a full meeting of the committee of the National Association, held on Saturday, the 12th of April.

Second.—The modifications required in Sir James Graham's Bill, as agreed upon by the same bodies, and also confirmed by the committee aforesaid.

Third.—A copy of a report of a conference, between the Right Honourable the Secretary of State for the Home Department, and a deputation from the National Association of general practitioners, held at the Home Office, on Saturday, the 18th of April, as entered on the minutes of the association.

the particulars of the whole of which documents were published in the "Transactions" of the association, bearing date the 18th of April.

They received a letter dated the 22nd of April, informing them that, on the 18th of April, the court of assistants of the Apothecaries' society had passed the following resolutions:—

First.—"That the suggestions for heads of charter for the incorporation of the general practitioners in medicine, surgery, and midwifery, with the modifications introduced by the society, and their reasons for those modifications, be presented in writing to Sir James Graham, with their desire that a charter with such powers, be granted to the general practitioners, and that upon such charter being granted, the society is willing to resign the control over the examination and education of the apothecary, as now possessed by them, under the Act of 18 5

"Second.—That the Act of Parliament committee be empowered to carry out the objects of the foregoing resolution."

and the committee were further informed that the society had already addressed Sir James Graham, in conformity with these resolutions.

The Society of Apothecaries received a letter from Sir James Graham, dated Whitehall, April 25th, in which it is stated, after acknowledging the communication above referred to, that the Right Honourable Baronet is "not indisposed to take into consideration any draft of a Charter of Incorporation which shall be presented on behalf of the General Practitioners, provided that the parties presenting it shall first satisfy him that they have full authority, on behalf of the National Association, to accept such a charter as the Crown may be advised to grant, and on behalf of your Society to relinquish your present privileges as soon as the terms of the proposed Charter shall be adjusted, under the sanction of her Majesty's advisers, to the satisfaction of the petitioners."

Upon which the Society immediately communicated with the committee to the effect, that they had appointed two of their members, Mr. Bacot, *Warden*, and Mr. Ridout, to form, with two or three members of the Committee of this Association, a joint Deputation possessed of the powers required by the Government, as intimated in the letter of the Right Honourable Sir James Graham.

Accordingly your Committee, by an unanimous vote, on the 22nd day of April, appointed Mr. Pennington, Mr. Bird, and Mr. Ancell, to fulfil this important trust. They have every reason to believe that the confidence they repose in the zeal, intelligence, and discretion of those gentlemen,* is participated in by the members of the association generally, and they had no hesitation in vesting them, for this special purpose, with the powers given to the committee at the Public Meeting of the 14th of March.

As respects this new, and they trust final negociation, the principle of representation and that of equality of privileges having been universally understood and agreed upon, different views were known to exist as to the extent to which the one should be carried, and the manner in which the other should be applied. The moment your committee were made aware that the subject of a charter was seriously entertained by the Government, and that a discussion of its details was likely to be called for at the Home office, although fully authorised to act definitively on the part of the general practitioners, they felt it to be their duty, as intimated in their conference with the Apothecaries' Society, to defer to the members of the Association, before a final step should be taken. There were two points in particular, respecting which the committee deemed it advisable accurately to ascertain the opinions of the members of the association—the Franchise, and the Qualification for Membership of Council—these being, perhaps, the two most important matters of detail appertaining to such a charter. They were most anxious to do this, that they might be enabled to lay before the Government the opinion of the majority upon these subjects, and to secure to it its proper weight. As most of the individuals present are probably aware, schedules have been distributed to every member of the association, a great proportion of which have been returned. Many members of the association reposing confidence in the committee will, on that account, perhaps make no return; some returns probably have not had time to reach the office, but the result of this canvass of the opinions of the association, so far as it has reached the committee, is—

In favour of an unrestricted Franchise	252
In favour of a 2 Years Franchise	9
In favour of a 5 Years Franchise	1476
In favour of a 7 Years Franchise	11
In favour of a 10 Years Franchise	535
In favour of an Unrestricted Qualification, every Member from the period of his entering the profession being qualified for election as a Member of the Council	111
In favour of a 10 Years Qualification	376
In favour of a 15 Years Qualification	1714
In favour of a 20 Years Qualification	58

Taking the double return the numbers are:—

In favour of a 5 Years Franchise, and 15 Years Qualification	1165
In favour of an Unrestricted Franchise and Qualification	93

The heads of charter have been many weeks before the profession, so as to give every opportunity for the members to advise the committee of their opinions. The conferences between the Society of Apothecaries and the association, on the subject of these heads, have also been published in the Transactions. The committee have not been made aware of any difference of opinion, except on the two subjects above referred to, and they may therefore fairly assume that not only upon points involving principles, but even as respects the details, with the above exceptions, the members of the association are perfectly agreed.

Since there is no reason to doubt, that in the forthcoming charter the Government will agree to that part of the suggestions which provides for the provincial members of the new incorporation a representation on the council, the committee have thought it desirable that its number should be considerably augmented by the addition of gentlemen residing beyond ten miles from the Royal Exchange. It is not for one moment expected that such members could take part in the preliminary business of this great undertaking, nor can the provincial members of a new council take part in the daily routine of business; but, in the one case, as in the other, questions may arise on which it would be most desirable to obtain their deliberate opinions and assistance in their respective districts; and as in the government of the new college—periodical conferences between the London and Provincial members, requiring the attendance of the latter in London will be necessary, so, during the present arrangements, the committee on the one hand, might find it most requisite to summon, and the provincial representatives to attend a meeting of the committee for some special purpose. They are aware that they will have to consider well the different counties and districts, with a view to representation, and they take it for granted that those districts which contain provincial schools will be especially entitled to members of council. They would have been most happy to lay before the meeting a list of Provincial Members for election, but they are totally unprepared to do so, and they consider that a plan must be devised to obtain the opinions in this matter of practitioners residing on the spot. It is obvious that the arrangement of this part of the business must take considerable time and attention, but if the meeting should concur in the propriety of the suggestion, it will probably empower the committee to make such addition to its number, from members of the association residing beyond the prescribed distance.

Although several unworthy attempts to disturb the proceedings, and to weaken the organization of the National Association, have been made, it affords the committee the greatest satisfaction to be enabled to report to the meeting, that the Association continues in all its integrity,—it numbers considerably above 4000 members. The enrolment proceeds daily—the provincial organization has been rendered more effective; notwithstanding the efforts above alluded to, not more than half a dozen members have been induced to withdraw, and not half a dozen letters have been received disapproving their proceedings. They have continued to conduct their business with the most perfect unanimity. Votes of confidence have been passed by many of the Metropolitan and Provincial Associations; the most flattering communications have been received from individual members, and the subscriptions have increased. Under these circumstances, the committee feel that it would be disrespectful to notice, with the view of defending either the committee or the association, the untruths and misrepresentations which a few individuals have thought proper to promulgate.

The committee considered it most important that the National Association should nominate some member as the representative of the association in the House of Commons, to whom they could make fully known the case of the general practitioners in reference to the Medical Bill. No gentleman was suggested so likely to receive the confidence of the profession as Mr. Hawes. He has interested himself in medical politics for many years. He is universally esteemed in the House by the members of all the great political parties. Accordingly, they passed a resolution respectfully requesting Mr. Hawes to become the advocate of their claims in Parliament, and he has most handsomely undertaken this onerous duty. Mr. Hawes has since been in repeated confidential communication with the committee. The committee have reported this nomination in their transactions, and have also addressed a circular letter to all the members of the House of Commons to the same effect, requesting their support. They have authority to state that the result of these measures is already, that the claims of the general practitioners of medicine, surgery, and midwifery, in this kingdom, are better understood by the legislature, and that they have a right to believe that, if it should become necessary, a large and powerful party would be found to advocate those claims in the two Houses of Parliament.

As regards the general affairs of the Association, it affords the committee much satisfaction to inform the meeting, that the donations to the fund for defraying the expenses of this movement increased considerably, as the necessity for a separate Incorporation became more manifest, and its attainment more probable. Since the publication of the last "Transactions," they have received:—

The accounts of the association have been audited, and the auditors' resort will be laid before the meeting as a supplement to the report of the committee.

In consequence of the numerous committee and sub-committee meetings which the rapid increase of the general business of the association rendered necessary, it was found that the proprietor of the Hanover Square Rooms would be unable to afford sufficient accommodation during several months of the year, in which the rooms were engaged for other purposes. The stability of the association being no longer doubtful, and the greater part of the house, No. 294, Regent-street, being available upon fair terms, your committee deemed it advisable to engage those premises at a yearly rental of £170, with the proviso, that should the association deem it expedient to make any change of locality, the committee are at liberty to cancel the agreement at the expiration of six months, on paying the rent due, and a fine of £20.

The committee have the most heartfelt pleasure in stating they are firmly of opinion, that the long agitation of our essentially peaceful Profession will speedily be brought to a satisfactory termination, and that the just and liberal views expressed by Sir James Graham in the House of Commons, on the 25th of February, in respect to the General Practitioners—a class created by the public for its own necessities and welfare—will ultimately prevail. They have every reason to believe that the Right Honorable gentleman's determination to maintain their honor, their station, and their attainments, has been fortified—and after hearing the several pleadings of all the different interests involved, these interests will be settled equitably and justly, as respects each other, and for the good of the profession and of the public. They are convinced that Sir James Graham, who holds so distinguished a position in the country, is not only satisfied with the correctness of the views, but is fully determined to adopt them as his ultimate policy.

Finally the committee beg to remind the meeting, that in so large an aggregate of intelligent men as the association comprises, it would be unreasonable to expect perfect unanimity. Varieties and shades of opinion must arise. Where differences exist all and every one cannot expect that their particular views will prevail. Moreover, we, the National Association, however numerous and influential, have not the settlement of these differences. We have to deal with a minister of the Crown; that minister has again to deal with the parties representing the various contending interests. He cannot negotiate with large bodies, and it is incumbent on you to give a discretionary power to those in whom you place confidence. Your committee are aware that by the resolution of March 14th, such a power is in their hands,—but they deemed it right again to defer to you, before taking any final step. It will be their duty to carry out your views, and particularly those of the majority, as far as possible, on points of detail, and in the exercise of their best judgment to accept or reject the measure which the Government may at last determine upon. On principles we all stand together—there is no difference of opinion. We are all in favour of a Representative Government. We hold that every member of the new Incorporation, who does not by his own misconduct disqualify himself, should be eligible to the different offices of honourable distinction. That as a class we ought to possess the control over the education of our own members, that the course of education ought to comprise all that is necessary, to qualify for the practice of medicine, surgery, and midwifery, and that being the medical attendants of more than nine-tenths of the community, we ought to be able to hold medical and surgical appointments, at the option of the public. We hold that every qualified member should be alike entitled to the franchise, and to seats on the Governing Council, and that the highest post of honour in the gift of the members, should be looked forward to as the reward of the most distinguished merit.

An institution in this kingdom, founded upon these principles, would develope energies in our profession hitherto unthought of, would lead to an accumulation of scientific and practical knowledge beyond any parallel—would be of unbounded utility to the community, and would promote the welfare of the human race.

On the conclusion of the reading of the report, it was greeted with reiterated applause.

ABSTRACT OF THE AUDITORS' REPORT.*

1845 May 3rd.—To cash received by the treasurer	£1459	14	8
— By cash paid	633	18	9
— Balance in treasurer's hands ..	825	15	11

Audited and approved May 3, 1845,

P. Hood,
John Miles,
Ebenezer Smith.

Mr. Jones, of Ross, in proposing the first resolution, to the effect "That the report just read be received and adopted," expressed the great pleasure he felt at the enthusiasm which had been shewn by the members of the association.

Mr. Barnes, of Notting Hill, seconded the resolution, and complimented the secretaries on the talent displayed in drawing up the report.

Mr. Webb, of Marylebone, supported the report, the reading of which had given him great satisfaction; and he was very glad to find that every thing was going on in the right course. He (Mr. Webb) was the first man, at a public meeting, in September last, to speak in favour of the incorporation of the general practitioners, and he then said that it would certainly be obtained, if it were sought for steadily and perseveringly. He was happy to find that he had been a true prophet. With respect to the schedules which had been sent to the members to obtain their opinions on the question of franchise, he had voted for unrestricted qualification, as he thought that there were faults attributable to age as well as to youth; but as the majority had decided for a limited restriction, he should support their decision, on the principle that the will of the majority, in such cases, shou'd be the law. He considered that the opinions of the profession might be obtained with respect to the election of provincial members on the committee, by the transmission of voting papers to all the country members. The returns thus made would enable them to ascertain the feelings of the association, on that question.

Mr. Hillier rose, but seeing the wish of the meeting for Mr. Hawes to address them, he gave way, and

Mr. Hawes, M.P., then presented himself, and was received with loud and protracted cheering. He assured the members that he had no wish to intrude himself on the meeting, and had, indeed, great reluctance to take any prominent part in their proceedings at all. At first, he had not had any intention to attend the meeting, but as he had not any parliamentary duties to perform that night, he had looked in, in order that he might be able personally to ascertain the feelings of the profession. He had no idea that any allusion would have been made to him in the report; otherwise he would not have been present. There was another gentleman—the hon. member for Finsbury—who had an extensive acquaintance with the subject, and with whom he had acted for years in seeking to uphold the rights and privileges of the general practitioners, and he trusted, that now they had advanced to the position they at present occupied, there would not be any difference of opinion between them, and that they would act together with perfect cordiality. The general practitioners had been actually forced to seek for a charter of incorporation. If there had ever been any who had thought such a step one of doubtful policy, that doubt, he thought must now be removed, since the college had not shewn the slightest inclination to co-operate with them. He would not use the word "repudiate," because he did not wish to say anything to the injury of that learned body; and he was sure, that as the general practitioners were now about to obtain a charter of incorporation of their own, that they would look back upon the past with forbearance and kindly feeling. This is a very important period for general practitioners, and every thing depends on union. There should be no desire on their part to act with hostility to either the College of Physicians, or of Surgeons; they should content themselves with obtaining their own rights and privileges, as their charter of incorporation would secure a good education and a just examination for future candidates, and would prove a bond of union between them when in practice. He believed that no one could object to this. When he first heard of the intended separation, he must confess, that his wish had been to effect their reunion with the College of Surgeons; but from the position taken by that institution, he was now of opinion that nothing remained for them but to have a charter of incorporation for themselves. Mr. Hawes then eulogised the report which had just been read, as it showed, he said, the desire of the committee to act in accordance with the views of the majority of the members. With respect to details, they should be left to the committee to arrange, in whom every confidence should be placed. The charter, which would do all for them that a charter possibly could do, was about to be granted; but if any indication of disunion, or distrust, were manifested by the association, it might prove an obstacle to its being granted. Mr. Hawes then disclaimed having voluntarily sought to be placed in the position which he occupied with respect to the association, and hoped that he and his friend, the member for Finsbury, would still act together with unanimity; and if any difficulty arose between the Government and the committee of the association, would act together for its removal. He himself would not withhold either labour or interest, for their advantage; and he again strongly urged unanimity of feeling, without which they could not gain that position in the profession, which they sought, while it was of equal importance that their opponents out of doors should not derive any advantage from their disunion. He could have wished there should have been perfect unanimity, but that he knew was an impossibility; still he felt assured that there was not any gentleman present who had not the welfare of the profession at heart. On so important an occasion it was necessary that every one should put his shoulder to the wheel, and endeavour to obtain a liberal and comprehensive charter of incorporation. When the charter was obtained, he trusted the council would take a lesson from existing corporations, and seek to render it useful by obtaining the confidence and respect of their members. (Continued cheering.)

Mr. Hillier said he had risen previously to express his wish that the charter of the college could yet be altered in favour of the members, and that he had had reason to believe that some legislative measure would be enacted to compel the college to modify the charter; but he now stood boldly forward to say, with Mr. Wakley in the house, after what had been stated by Mr. Hawes, that he now held out the flag of truce (loud cheers). The honourable member for Finsbury had said that the college would be compelled to repair the injury they had done; but when he now heard confirmed by Mr. Hawes, what he had learned previously from others—that no hope remained—he thought it would be madness not to form a new incorporation. He approved of the proceedings of the committee, and believed that faction was now disarmed; if it were not so, he ceased to be a member of that faction (great cheering). He hoped to see the member for Finsbury co-operate with the member for Lambeth in obtaining their rights and privileges. It was not their business to dictate to the Minister what to do, but to tell him what they wished to have done, and then leave the legislature to do the rest. A more able report than that which had issued from the committee he had never heard, and he was assured that none but honourable measures were intended to emanate from them. If Mr. Wakley addressed them, he (Mr. Hillier) was quite certain that he would do so in the spirit of conciliation, as he (Mr. H.) believed that

---

* Since the above report was made, upwards of £115 have been received by the treasurers, including ten guineas from the South Gloucestershire Association, and £34 from the Finsbury Association.

his heart was in the right place. He concluded by warmly supporting the resolution (cheers).

Mr. Wakley regretted that Mr. Hawes had left, which he considered unfortunate, as his object had been to ascertain the feelings of the profession, and yet he had left before any of the questions which were to come before the meeting had been fully discussed. He was quite sure, from the tone of the meeting, that whatever difference of opinion might arise, that those questions would be discussed with gentlemanly feeling. As a very old medical reformer, he trusted that he would be allowed to express his opinions with freedom—he could not act so cowardly as to do otherwise. He had fought the battles of the general practitioners for years, through good and bad report, and he had now the satisfaction to see them occupying the position which it had been his highest ambition to see them hold. They were now able to fight their own battles. Among so many thousands, a difference of opinion must naturally arise; but it did not thence follow that there was a want of integrity on either side. He had differed in opinion with the committee, and had condemned their proceedings, and he here, in perfect good humour, repeated that condemnation, believing that the course they had pursued was calculated to damage the cause;—nevertheless, they might be right and he wrong; but acting, as he did, on the part of 20,000 practitioners (loud cries of no, no), it was allowable for him to express such opinions. One ground of complaint against them was the secrecy with which they transacted their business, and their refusal to sit with open doors (ironical cheers, laughter, and hisses). Did he condemn their proceedings with the view to do them injury? (yes, yes.) He had no desire, however, to rake up old grievances, but was content to let by gones be by-gones, clinging to the good, and taking warning by the evil for the future. His friend who had just addressed them, had expressed his belief that his (Mr. W.'s) heart was in the right place. He hoped it was, and his head too, but he thought that Mr. Hillier had lost his. He (Mr. Wakley) thought that they should still seek to conquer the council of the college, and not be driven from their own portals. In the report it was stated that such hope was given up. (Yes, yes.) A surgeon is a perfect practitioner. (No, no.) He did not mean a paltry pure, but a properly educated surgeon, one who would not fear examination before any board, one who could be called a qualified man, and was prepared to practice his profession in every field of medical science. Such a man he called a surgeon. He had sought to obtain a committee on the subject, but there was not any House, or else he would then have been debating the question on the floor of the House of Commons. The minister had done them injustice, to which they should not submit; nor be driven from their own college. The College of Surgeons had a most splendid library—(what of that?)—and a most magnificent museum, and there they should be located. He would fight for that, even if he fought alone; and if every effort failed, then he would join to obtain the charter of incorporation for the general practitioners, and would build their college on the ruins of the other. His communications with the members of the association led him to believe that they were in favour of reunion with the College of Surgeons. (No, no.) Their efforts for the last twenty years had been directed to diminish, not to increase the number of medical corporations, and that they should receive their diplomas from one institution only. He denied the right of the legislature to affix the brand of inferiority on any man who courted inquiry into his qualifications, and inquired what right the college had to institute the new grade of fellows? They were sure to succeed in regaining the college, if they were determined to do so; all that is requisite is, unanimity and determination. Never were there any public men whose conduct in the discharge of their public duties, was so bad as that of the council of the College of Surgeons. They had sworn to uphold the dignity and respectability of the profession, but the answer they had sent the association was full of arrogance and empty boasting. It was indeed the best thing they could do next to receiving them with open arms, because it showed the feeling of animosity by which they were governed, and also showed the association its true position. Look to the manner in which the charter had been obtained, and he would then ask if men in possession of common sense would submit to be thus deprived of their rights and privileges. He then referred to the meeting of the profession in 1826 at Freemasons' Hall, reiterated his condemnation of Mr. Lawrence, until he was stopped by continued cries of "question, question." They should not adopt the report suddenly; those who mean honestly, do not object to deliberation. They had been petitioning for medical reform, and the representative principle in government up to 1843, and then came the charter of the college, granted without any previous attempt having been made to get the suffrages of the commonalty. It was obtained sneakingly, and by back-stairs influence. It gave the council power to elect fellows, and they had chosen their own sycophants and dependants, and a precious set of fellows they were. They have whipped and castigated the members, who now turn round, and say, "Thank you, gentlemen, we will run away, and give you no more annoyance." Instead of submitting thus, however, they should demand, with one voice, that the General Practitioners be incorporated in the college of Surgeons. He had been anxious to learn on what terms the new charter would be granted, but had not succeeded: he had been given to understand, however, that there would not be inferiority of privilege; but what position would they occupy, unless, like the Apothecaries' Company, they possessed the exclusive privilege of compelling all to come before their board. Mr Wakley then referred to the operation of the Medical Bill, as at present framed, by which the licentiate of medicine and surgery was to be examined by the colleges of Physicians and Surgeons; and he was desirous to know if the College of Surgeons remained, and possessed equal privileges with them, who would seek their diploma?—Students hitherto had no remedy, but were compelled to go to Apothecaries' Hall; but if by law they had the choice, and could go to the College of Surgeons, which of them would pour their fees into their funds? (Cries of "All! all!") The council of the college were anxious they should obtain their charter—("No, no!")—at least they did not oppose it; and if they could agree with the minister in the reservation of their exclusive privileges, their friendship was but hollow, and they were acting the part of traitors. He wanted, therefore, to know whether they were to have any exclusive privilege, as if they were to fail, after all, it would give their enemies an additional triumph over them. He would again enquire what need was there of a new incorporation, if they could make the council repair the injury it had done, which they would obtain, if they were but duly organized. Their committee did not number any members from the country, as it should do. It was not necessary that those gentlemen should leave their practice to attend the meetings; they might nominate some one in town, whose opinions were known, as their representatives (loud laughter). At present they were not a representative body; they were quite at sea. (Loud cries of "No, no!" hisses, and exceeding clamour.) He was delighted with that part of the report which recommended the election of some members from the provinces on the committee. He believed the country practitioners were almost to a man, including even the licentiates of the Apothecaries' Company, in favour of a reunion with the College of Surgeons. (Cries of "No, no!")—"Question!"—"Time!" &c.) He hoped it would not be required that the report be adopted at once. In the first place, these meetings should be repeated every week.—(Loud laughter, ironical cheering.) Is it then too much to ask the members to come here once a week, to watch over the proceedings in another place, where they want the stimulus of such meetings to correct them when wrong, and to spur them on by their approbation when they are in the right? Four or five such meetings would be sufficient; and he did not think it was asking too much when an important bill, so materially affecting the interests of the profession, was pending.—(Laughter, hisses, and partial cheers.)

Mr. Clifton rose, with some hesitation, to address them after the display made by their friend—(he trusted he was right in using that word)—the member for Finsbury. He was with him to a great extent, in saying that, as a body of medical men, they had been most grossly treated by that college, to which they had looked up for support and honour: so far he agreed with him; but he thought that he (Mr. Wakley) had travelled beyond the ordinary usage of public meetings, and had used arguments which, although good and cogent, were unfortunately not applicable to their present state. He (Mr. Clifton) then read a resolution, passed at the first meeting in these rooms, constituting the association for the purpose of obtaining a charter of incorporation for general practitioners—(cheers), and for taking such other steps as may be deemed necessary. Such was the original constitution of the committee, and there was not a word said about the College of Surgeons in that resolution.—(Interruption and cheers.) At the last meeting, the power of the committee had been confirmed, with that express object in view; and it was therefore evident that the greater part of Mr. Wakley's remarks were irrelevant.

At this part of Mr. Clifton's speech there was considerable interruption, and Mr. Hodson Rugg rose and attempted to address the chair, but such was the marked dislike evinced towards him by the meeting, that in spite of Mr. Wakley's appeal in his behalf, he could not get a hearing. The disturbance continued for nearly half an hour, Mr. Rugg obstinately persisting in attempting to address the chair, until at last, after renewed calls for his expulsion, the venerable President was forced to intimate, through Dr. Webster, that if he (Mr. Rugg) continued to interrupt the business of the Association, he should order his removal. Silence having been obtained by this threat,

Mr. Clifton resumed, and observed that the committee had been charged with the performance of a certain duty, and were not directed to hold any communication with the College of Surgeons, which they had done only at the express desire of Sir James Graham, who, at their first interview, had stated that the only impediment to granting them a charter of incorporation consisted in their separation from the college. They had felt it necessary to take that step in deference to Sir James Graham's opinion, and also the better to carry out the resolution, that they were to take every requisite step to obtain the new charter of incorporation, but the answer of the college to their communication left no hope of reconciliation either in the minds of the committee, or of Sir James Graham himself. There was therefore no alternative but to press onwards, and obtain that charter which alone could place them in the position they ought to hold. They were now within reach of that object which he believed was desired by the great majority of their members. They had letters in their possession, which shewed that the feeling throughout the country, was in favour, not of a reunion with the College of Surgeons, but of a distinct and separate charter of incorporation (cheers). He would assert this without fear of contradiction, and the letters which had been received by the committee from all parts of the country, confirmed his statement. He had little else to add, except that he agreed with the Member for Finsbury, that there was little to be said in favour of the College of Surgeons: they have much to complain of, and cannot get redress, save by taking an independent position in the profession, when the experience already obtained will guide the committee in the direction of the studies and examination of the future candidates, and will enable them to raise the position of the future General Practitioner far above any competition with any other body; and then there will be no other competition but as to who shall best perform the high and important duties thus assigned them. Let them obtain that position of rivalry, and there will not be any reason to fear the result. Mr. Clifton then spoke of the zeal and assiduity of the committee in carrying out the objects committed to their charge—referred to the letter that had appeared in the *Lancet*, purporting to come from a member of the committee, and completely disclaimed by them, and finally

characterized the abuse and vituperation lavished on them, as utterly unjustifiable (loud cheers).

Mr. Sparkes observed that the question before the meeting referred to the adoption of the report of the committee. A matter of so much importance, and affecting so much the interests of the profession as that report, was deserving of grave and serious consideration; and it should be discussed with firmness. He, (Mr. Sparkes) had been pleased to hear Mr. Hillier, formerly an opponent, who in the most candid and generous manner had approved the report, and given in his adhesion to the propositions now entertained. The member for Finsbury had had a very fair hearing given him, and he hoped he would always get as fair a hearing in the House, (cheers and laughter.) He, (Mr. Sparkes) did not think the College of Surgeons was a body calculated to send forth medical practitioners capable of attending to the bodily welfare of the public, and he asked what had been the utility of the Society of Apothecaries; eminently conducive to the honour, dignity, and utility of the profession, and he thence deduced the necessity of a third estate—the new incorporation; in fact that the profession should be tripartite. He did not wish it should go forth that the general practitioner was still willing to coalesce with the College of Surgeons. In the new institution, the council would have to regulate the education of candidates and their subsequent examination, and watch over the general conduct of their members afterwards, so that there then would be no fear of the charge against their members of being 'vendors of nostrums, felons, professional paupers, or writers of indecent advertisements'! (cheers and great applause.) In the present instance, he (Mr. Sparkes) thought the Member for Finsbury to be in a minority of sound reasoning, and he begged cordially to support the report of the committee.

Mr. Burrows, of Brighton, said that he attended the meeting as a deputation from the medical men of Brighton, and had much pleasure in saying that he was authorised to give the most cordial approbation of the past, and support for the future. When he first sought to establish a branch of the association at Brighton, every medical man he called upon said, "Oh! but you will break up the College of Surgeons; don't do that!" But now, ever since the reply of the college to the profession, they felt that there was nothing left them but to found a new college of their own. He then expressed the pleasure he had experienced at Mr. Hillier's speech, and hoped that all would be unanimous in furthering the interests of the profession.

Mr. Streeter observed, that in holding up his hand for the adoption of the report, he did not waive any moral or legal right he had obtained at the College of Surgeons (certainly not). He should support the report most cordially, for he believed the time had now come when the general practitioner must have a college of his own. He regarded him as being the oldest medical practitioner in this country, and was firmly of opinion that, by the common law of the land, he was entitled to practice medicine and surgery, notwithstanding any privileges possessed by the barber surgeons. Although he was now heart and hand in seeking for the new charter, he had not taken that step without mature deliberation. The present was not the time for taking up the quarrel with the College of Surgeons, but he was not inclined to let it drop unnoticed (no, no). Believing that the Crown can do no wrong, and that the Minister had been grossly imposed upon, he thought the charter was voidable; on that point, however, he would not speak farther then. Mr. Streeter concluded by stating that he conscientiously supported the report of the committee.

Mr. Gray proposed, and Mr. James seconded, an amendment to the following effect:—That the consideration of the report be adjourned till Thursday week!

Dr. Webster had been unexpectedly called upon to say a few words in the character of a conciliator. He had heard the speeches of Messrs. Hawes and Hillier with great pleasure, and trusted that Mr. Wakley would re-consider his opinion respecting the College of Surgeons, and put his shoulders to the wheel to obtain, in the mean while, the charter of incorporation for the general practitioners. They should get this, if it were only as a means to enable them to fight the college on more equal terms; and he agreed with Mr. Streeter, that in obtaining the new charter they did not abandon any privileges previously acquired. With regard to the charge of secret committees, it was incorrect; their proceedings were published in the medical journals, and afterwards in their own transactions, when they were not fairly represented in those journals. Everything that occurred was published, and he asked how could business be carried on if they had such meetings as that every day (loud cheers). He would appeal to the member himself, and ask what kind of deliberative body it would make. There must be an executive possessing the confidence of their constituents, and the power to carry out their objects. He urged the association not to refuse the boon that was offered them because they could not get all they wanted. They were within an ace of obtaining that which would raise them in position, and in general estimation. He set out as a medical reformer with the one faculty system, and he believed, if this charter was obtained, that he should live to see the profession incorporated into one great faculty.

Mr. Cooper hoped that by a few words he might be able to pour a little oil on the waters of contention. He recommended Mr. Wakley to persevere in endeavouring to force open the portals of the college, and he was sure the members would gladly avail themselves of his services; but, from what he had heard, and especially as Sir James Graham, with a majority in the house, had refused to interfere, he was not sanguine of success; if he failed in this, he might then try to obtain the new charter. He expressed himself as better satisfied with the proceedings of the council, than he had expected to be when he entered the room.

Mr. Ancell having previously given notice that none but members should vote, the amendment proposed by Mr. Gray, and seconded by Mr. James, was put *seriatim*, when fourteen hands were held up in its favour, and eight hundred against it.

The original motion was then put, and carried by acclamation.

Mr. Wakley then, in a speech which was interrupted by the most tremendous uproar, proposed—

"That it is the decided opinion of this meeting, that the general practitioners of England and Wales should be invested with the power of electing the council of the College of Surgeons, and that the exertions of this meeting be directed to the accomplishment of that object."

Mr. Rugg seconded the resolution amidst exceeding disturbance.

Mr. Headland said he was about to propose a resolution as a substantive motion, but he should now propose it as an amendment to Mr. Wakley's resolution. It was to the following effect:—

"That, in order to secure the more effectual cooperation of the provincial members in carrying out the ultimate objects of the association, the committee be empowered to add to its numbers, members residing above ten miles from the Royal Exchange who are general practitioners."

If this amendment be carried, it will then be necessary to ascertain the speediest way of learning the feelings of the provincial general practitioners, with respect to their representation. He had no doubt, in his own mind, that they were in favour of the new incorporation. There were among them as able surgeons as were to be found in this country, and he believed that if eventually they obtained the charter of incorporation, they would be able to send forth as good surgeons as the existing college.

Mr. Davis, of Hampstead, reluctantly came forward, but passing events had forced him to do so. He then referred to his own career as an army surgeon and country practitioner. He said that formerly he held the rank of a surgeon—it was now difficult to say what rank he held. He had in his possession two diplomas from the College of Surgeons, one granted in 1800, certifying his qualification as an army surgeon, and the other granted in 1813, certifying that he was qualified to practice as a surgeon anywhere, and yet now the council declare him to be fit for common exigencies only. Mr. Davis seconded the amendment.

Mr. Crooke drew attention to the attempt made by Mr. Wakley to destroy the proposition which had been just carried by a side-wind. The object of that proposition was to receive and condemn or approve the report of the committee. It had been approved of by a large majority, and Mr. Wakley afterwards attempted to defeat it, by proposing a resolution, which went directly counter to its especial objects, and he said that the gentlemen present were called on by the member for Finsbury to stultify their previous vote. He wished to hear discussion, that he might be able to say to the House of Commons, "See how divided they are!" (great applause).

Mr. Wakley attempted to deny that he sought to counteract the effect of the previous resolution by a side-wind; but the feeling of the meeting was so strongly against him, and was so forcibly expressed, as to render him nearly inaudible. He remarked that the difficulties that had arisen were caused by the want of bye-laws (continued hissing)—he had not understood that their object was a new incorporation (oh, oh!).

Mr. Ancell, in a well-timed and lucid address, showed that the resolution proposed by Mr. Wakley could only be put as a matter of courtesy, as it was totally at variance with the report, on which alone resolutions could be based. The association was instituted originally to obtain a Charter of Incorporation of General Practitioners, and they could not legitimately entertain the proposition just submitted. As an act of courtesy, however, and under that protest, it would be put.

Mr. Wakley said, that if Mr. Ancell's views were correct, he had been labouring under a mistake. He had thought the committee had the power to endeavour to replace the members in their proper place in their own college. As it was otherwise, he would beg to withdraw his resolution (applause) but still he could not concur in their determination, which he believed would cause great dissatisfaction throughout the country, (no.)

The amendment of Mr. Headland was then put as the original resolution, and carried unanimously.

Mr. Daniels, of Ramsgate, then proposed the next resolution, as follows:—

"That the return of the opinions of the members of this association being unequivocally in favour of a five years franchise, and also unequivocally in favour of a fifteen years qualification for a seat on the council, it be an instruction from this meeting to the committee to use its best efforts to secure these conditions in the new charter."

Mr. Warner of Cirencester was glad at being able to congratulate the members on being so near obtaining their objects. As far as his experience of the committee went, it was anything but close; the country members were invited to attend, and he believed that nothing occurred which was not published. Although an old reformer, he had not joined any association, until he was led to enrol himself in the National Association, by some very cogent reasons which he found in the *Lancet*, urging the co-operation of all General Practitioners to obtain a charter of incorporation (laughter, and cries of 'that's a fact'). He then seconded the resolution, which was carried with two dissentient voices.

Mr. Fuller said that a most pleasant duty had been allotted him—that of proposing a vote of thanks to the Society of Apothecaries, for their liberal conduct towards the association. There was no man present but had heard of liberality and liberal sentiments; but here were liberal actions. These gentlemen were in the possession of power which they had used well, and which they now freely gave up for the benefit of the profession. This was an act to be proud of, as it added dignity to human nature. Mr. Fuller then read the resolution as follows:—

"That the thanks of this meeting are justly due, and are hereby given, to the Worshipful the Society of Apothecaries, for the liberal, consistent, and judicious conduct which has characterized their proceedings in the negociations with the association and with the Government, up to the present moment."

Mr. Squibb had much pleasure in seconding the resolution proposed by Mr. Fuller; and he did so the more readily, because, in these days, such in-

stances of corporate self-denial are of rare occurrence. Their conduct, on this occasion, stood in bold relief with that of the College of Surgeons.

Carried unanimously.

Dr. Cooke briefly proposed, and Mr. Yorke seconded the motion.

"That the thanks of the meeting be given to the editors of the *Times*, *Morning Chronicle*, and the other public Journals, which have so ably advocated the interests of the medical profession."

Mr. Cooper then moved a vote of thanks to the gentlemen comprising the committee, and mentioned, as reasons for placing confidence in them, the admirable report which had been read that evening, and their selection of Mr. Hawes, as their parliamentary advocate. He trusted that when the charter was obtained, their efforts would be directed to prove to the government and the public that they were deserving of the powers confided to them.

The resolution was as follows :—

"That the meeting hereby expresses its cordial thanks to the committee for their unwearied exertions on behalf of the great body of general practitioners, and its unqualified confidence in all their proceedings."

Mr. Hillier seconded the resolution, which was carried unanimously, and greeted with three cheers.

Mr. Randall then, in eulogistic but well-merited terms of praise, proposed a vote of thanks to the secretaries, in the following terms :—

"That this meeting desires to express its cordial thanks to the honorary secretaries, for their arduous, valuable, and disinterested labours."

Messrs. O'Connor, Clifton, Propert, and Bowling concurred in speaking in the highest terms, of the energy, zeal, and untiring assiduity of the secretaries; and stated that the position now acquired by the Association was mainly due to their exertions.

The resolution was then put and carried by acclamation; it was received, as was also the succeeding resolution, with three cheers, and one cheer more.

Mr. Sparkes then proposed the last resolution, which was seconded by Mr. Wooldridge, Southampton, and carried unanimously :—

"That the thanks of this meeting are hereby given to our venerable and highly respected chairman, for the benefits conferred on the association by his presidency over it, and especially for his conduct in the chair on the present occasion."

THE GOVERNMENT BILL.
IMPORTANT ALTERATIONS.

Sir J. Graham, in moving that the Physic and Surgery Bill be committed, observed that his object was to introduce into it some very important alterations. On a former occasion he had expressed a desire to adjust the differences then existing between the great body of general practitioners, and the governing body of the College of Surgeons. He was sorry now to inform the house that he was afraid that those two bodies were irreconcileable. The College of Surgeons was in possession of a charter, giving them great privileges, great property, large powers, and high character. The general practitioners were a powerful body, and he believed that if you were to give them the power of returning members to represent them in the College of Surgeons, the representative power would soon reflect the character of the constituent body, and become the governing power of the college. Though he might incur censure for the declaration, he must say that he could not conceive the occurrence of any greater misfortune to the medical world, or to the British community, than that degradation of the science which would take place, if the College of Surgeons were to be transferred to Apothecaries'-hall; and he was afraid that if the 12,000 or 14,000 general practitioners were each to have a voice in the choice of the governing body of the College of Surgeons, they would displace the pure surgeons from it, and would convert it into an Apothecaries-hall. On the other hand, he confessed that it did appear to him, that although the objections of the general practitioners to the College of Surgeons and to the College of Physicians might not be well-founded, certain precautions which they desired ought to be taken. They stated that the physicians and surgeons had an interest in degrading the general practitioners, because when the level of the general practitioners was reduced, the condition of the physicians and surgeons would be exalted. Having thus said that some precautions should be taken on this point, and that the differences between the physicians and surgeons on the one hand, and the general practitioners on the other, were irreconcileable, *he concluded that it was indispensably necessary to incorporate the body of general practitioners*. Such an incorporation, while allowing students to hold during their studies, connection with the two other colleges, would afford him great facility in the attainment of an object to which he attached great importance, namely, that the entrance into the profession should be through one portal alone, whatever might be the department to which the student might afterwards devote himself. *He proposed that in all cases the student in medicine should undergo examination by one board, consisting of six surgeons and six physicians, or of such others as may be suggested, that the curriculum of study shall be controlled by it, and that the standard of competence should be common to all.* He likewise proposed that there should be *three distinct incorporations, one of physicians, one of surgeons, and another of general practitioners.* He proposed, in order to raise the character of General Practitioners, that *no person should be examined as such, until he attained the age of* 22 *years.* He then proposed that the College of Physicians and the College of Surgeons should form a joint board of examiners. The candidate for the profession would have to appear before a board of six physicians and of six surgeons, to be appointed by each of the colleges respectively. In conjunction with the Council of Health, this board of examiners should have power to examine and decide upon the merits of the different candidates who came before them. He then proposed that the College of General Practitioners should appoint another board of examiners, consisting exclusively of general practitioners, and that, if a student wished to be a general practitioner, he should go before the board of general practitioners for examination after the board of physicians and of surgeons had granted him a *liceat*. As to those students who wished to practise as surgeons and physicians, he proposed that they should go before the same joint board of surgeons and physicians, when they had attained the age of twenty-six years, but that those who wished to be surgeons should be previously examined by a board of surgeons, and those who wished to be physicians by a board of physicians. He had not come to the decision of incorporating a college of general practitioners without the concurrence of the apothecaries' company, which in the most handsome manner had declared its willingness to surrender all its existing powers. There would therefore be only three medical societies in England and Wales. In the bill which he now sought to amend, he proposed to repeal the Apothecaries Act, and by that measure to put an end to the five years' apprenticeship, which he considered derogatory to a liberal profession. He would retain the power of prosecution given by the Apothecaries' Act of 1815, and would transfer it intact to the new college of general practitioners. He proposed to make some alteration in the constitution of the College of Health. Some persons were of opinion that the elective power, by which some of its members were chosen, should be changed, and that the power of nomination should be transferred to the Crown, under certain restrictions. He did not intend to propose any such alteration, but would leave it to the house to make it in committee if it so thought fit. He adhered, however, to the principles of the bill as it then stood. He proposed that two general practitioners, chosen by the council of that college, should be members of the Council of Health. He also thought that the University of London should be represented in that council, and he wished to introduce a clause constituting the Chancellor and Vice-Chancellor of that university members of it. He then alluded to the exempting clause in his present bill with respect to the Universities of Oxford and Cambridge. He was happy to say that an arrangement had been made between the College of Physicians and those two learned bodies, by which, though the exempting clause would still be retained in the bill, it would be rendered inoperative. The agreement between the Universities of Oxford and Cambridge and the College of Physicians is this, that after a party shall have graduated in medicine, and obtained the degree of Doctor in either of those universities, he shall, if he think fit (and the temptation is great to induce him to think fit), come up to the College of Physicians for examination, which, on obtaining their diploma, will open metropolitan practice to him; and at that examination assessors from the universities are to be present, and to take part in it. (hear.) He proposed to omit clause twenty-eight, and to leave to public opinion, and to all public institutions, the power of deciding what class of practitioners shall be eligible for their medical offices. He would change the "inceptors" into licentiates, and having secured by the Council of Health a *strict* examination by the Colleges and high competency of attainment, he would make such changes that the residence at an University should be effectual. The question of intra-urban and extra-urban licentiates, he would discuss in committee on the Collegiate Bill; but before doing so, he would take care to lay before Parliament, copies of all the new charters. The registration should acknowledge existing rights, but give no additional one to the different classes of physicians. The simulation of medical titles should be, as before proposed, a misdemeanour; and no one but a physician should use the appellation "*Doctor*." He proposed then to go into committee *pro forma*, to immediately reprint the Bill, and postpone the committee to the middle of June, when the charters should also be proceeded with. Immediately after, or, if possible, before, he would lay on the table the charter of the *new* incorporation. Thus the whole measure would be before the profession, and the country would have time to fully consider it. If he failed in his present amended proposals, he should despair of any arrangement; but he had the strongest hopes of support in carrying out intentions to promote the public welfare, and increase the harmony and dignity of a most meritorious profession. Sir James Graham further stated, that in his new charter to general practitioners, the council should have forty-eight members; that the qualification for being on it should be fifteen years medical practice; that the elective power should be in the hands of general practitioners of ten years standing; and that the first councillors should be both M.R.C.S. and L.A.C.

Mr. Hawes approved generally of the Bill, and anticipated its success. Clauses 22, 23, and 26, would require consideration. He felt there was no danger in making the M.R.C.S. an elector of his college, but agreed that a reconciliation was hopeless. The numberless letters daily reaching him satisfied him that the measure would be well received.

Mr. Wakley said that he dissented altogether from the concluding statement of his hon. friend the member for Lambeth; and he believed that the alterations which the right hon. baronet had announced would be productive throughout the profession of the greatest possible dissatisfaction (a laugh.) One of the objects of that bill was to repeal the 55th of Geo. III., which prevented gentlemen who had received their medical education in Ireland from practising in this country. But the right hon. baronet meant to transfer the provisions of that act to a new corporation.

Sir J. Graham said—No. Any person who had passed an examination before a college of surgeons or a college of physicians in England, Ireland, or Scotland, would be entitled to practise as a general practitioner throughout the United Kingdom, and no such individual could be prosecuted under the Apothecaries Act.

Mr. Wakley *then would like to know of what value the bill was to be to the general practitioners?* He believed that to them it would be of no value whatever. It was a mockery of a benefit, and nothing more. Why did not the right hon. gentleman

admit the general practitioners to form a portion of that board, which it appeared was to be composed exclusively of members of the College of Surgeons and of the College of Physicians? The fact was that the right hon. gentleman had been acting entirely in compliance with the wishes of the ruling medical bodies in this country; and he had no hesitation in saying that the entire conduct of those ruling bodies towards the general practitioners had been most disgraceful; and yet that conduct was, it appeared, to receive the sanction of the legislature. The college had behaved to its members in the worst possible way. Everybody was complaining of it, and the only remedy was to transfer those gentlemen from their own institution to a second apothecaries hall. He would tell the right hon. baronet that such an arrangement was insulting to the parties in question; and if they tamely submitted to it, they would only show that they were entitled to no respect, and that they could claim no redress. Was the proposed college of general practitioners to be placed on the same footing as the College of Surgeons! No such thing, it was to be inferior in every respect; inferior in position, inferior in privileges, inferior in law. The fact was, that the right hon. baronet had yielded to the suggestions of the two governing medical bodies in this country; and then he had stated that the arrangement he had entered into was in conformity with the wishes of all parties.

Sir J. Graham—Including the general practitioners.

Mr. Wakley continued—Including the committee of general practitioners. But before that question came on again for discussion in the month of June, he believed that the right honourable gentleman would learn what were the feelings of the great body of the general practitioners upon that subject, and that he would find that they would not readily consent to be permanently denied the privileges which they ought to possess in their own college. He believed that the right hon. gentleman was of opinion that he could not alter the charter of the council even if he were desirous of doing so. But he (Mr. Wakley) was of a different opinion. Corporations should not be multiplied. Medicine and surgery were the same. All surgeons were physicians, and were entitled, therefore, to better treatment. The members should choose their own representatives in the council, and if formed of general practitioners, half the council should be fixed by charter to be pure surgeons. Every member of the council disapproved the last charter—for example, Mr. Guthrie. A college of general practitioners would not be respected. Every village and town had its Brodie; and thus the general practitioners in this country were the first medical body in the world, and for those Sir J. Graham was about to make, as he confessed, a new apothecaries hall.

Sir J. Graham.—I confessed no such thing.

Mr. Wakley would ask whether the right hon. gentleman would assent to have a committee appointed to inquire into the state of the College of Surgeons? ("No, no," from Sir J. Graham.) The right hon. gentleman refused. Well, then, he must admit the facts stated? Sir J. Graham —"I must deny the inference."—A laugh.) There would be no justice in refusing an inquiry.

Sir J. Graham.—There has been an inquiry.

Mr. Wakley.—That was in 1834. More proofs had accumulated since. He hoped the letter from the council to the general practitioners would be printed, without further delay, and laid before Parliament. It ought to have been printed before. Would the right hon. gentleman print it?

Sir J. Graham.—The House prints, not I.

Mr. Wakley believed that when the House was in full possession of information with regard to that college, the right hon. gentleman would not carry his bill; for it would then be apparent that these men ought not to be left in their present anomalous position, and that they should be removed from the degraded situation in which they had been placed by the charter. (Hear.) The memorial, it is said, was not sent by the college, but by the council.

Sir J. Graham.—It bore the Corporation seal.

Mr. Wakley.—But the members were never consulted upon it. Upon no occasion had the council called the members together to consult them upon any one subject. The college had received £400,000 since 1800, and had never established a single medical scholarship until four years ago out of their funds. (Hear, hear.) The whole proceedings of the college were unjust to the members, who, by their own talent and respectability, had most honourably established themselves in society, while from their own institution they received nothing but insult and indignity.

Mr. Warburton observed that—according to the Royal Commission to inquire into the management of the Scotch universities, the professors were considered rather lax in their examination of candidates for medical degrees in Edinburgh, because they were paid by fees, and consequently the more pupils they had the more they got, and therefore the provisions in the twenty-sixth clause, which proposed to constitute a joint board, composed partly by the professors of the university, and partly of the examiners of the college, might be held to give a less efficient check than the two examinations under the existing system. Would the privileges of general practitioners under the new charter be the same as before? (Sir J. Graham.—Yes.) He was friendly to reciprocal rights of practice throughout the country.

Mr. H. Berkely said the Council of the College of Surgeons had disgusted the whole country. Let them take the case of a man who was very well known in the medical profession, who was very generally esteemed, and was a man of great science — Mr. Dermott, a lecturer, who had several pupils under his care, many of whom had arrived at the very height of their profession. Would not the world consider the omission of such a man from being elected a fellow of the College of Surgeons a great slur? There was Mr. Frogley, of Hounslow, a very eminent man also, who had performed as many brilliant operations as their Brodies or their Listons, who had also to complain of the way in which he was treated.

Colonel T. Wood said there was a general discontent prevailing in the profession on account of their unfair exclusion from the honours of the college. He had presented a petition from Mr. Guthrie, who thought that an inquiry ought to take place; and if such an inquiry did take place, the college would, no doubt, be placed upon a footing which would be deemed satisfactory by the whole profession.

The house having gone into committee,

Sir J. Graham said,—the whole principle of the bill was this, that persons who were registered in Scotland or Ireland would have an equal right to practise here as those who were registered in England. He must express his great regret at the injury that had been perhaps inflicted upon some surgeons of undoubted character by the charter; but how was this to be avoided, or where were they to draw the line? It was said that this measure dealt harshly with surgeons in the army and navy. A selection of these gentlemen had been, however, made by Sir James M'Gregor, who was at the head of the army medical staff; and by Sir W. Burnett, who was at the head of the naval medical service. He was bound to say it was not his wish that the selection of councillors from the list of fellows should be made according to seniority. He should have wished to choose the governing body from the whole list, without observing the principle of seniority. It was, however, very much pressed by the council of the college of surgeons that seniority should be the test of qualification, to which he had reluctantly acceded. This arrangement was, no doubt, open to objections; *but he by no means despaired of bringing the council of the College of Surgeons to a sense of the hardship of this inconvenience, and to consent to some change in the charter.* His hon. friend, he was surprised to observe, had objected to one of those provisions which he had introduced as safeguards; he had objected to increasing the term of residence in Edinburgh from one year to two. He (Sir James Graham,) had inserted two years for the very purpose that there should not be that attraction from London to Edinburgh which he apprehended. He had bestowed great attention on this subject, more than on almost any other in the course of his life; he had honestly endeavoured to overcome the extreme difficulty, and, notwithstanding all the predictions of the hon. member for Finsbury, he was convinced this measure would receive the support of the general practitioners. Did not that honourable gentleman pay a visit last night to the general practitioners, and did he not find his views not in accordance with the great majority of general practitioners? (hear, hear, and laughter.) If he, (Sir J. Graham) had not been much misinformed, there was a very stormy meeting last night, more than 300 were assembled, and not above 10 or 12 agreed with the hon. member for Finsbury. The next time the subject was discussed they would be better able to judge what was the feeling of the general practitioner. He believed that the measure now proposed would satisfy the Colleges of Physicians and Surgeons; he had negociated with those who, he believed, represented the general practitioners of England, and if he should happily succeed in pleasing those three bodies, he believed he should have no difficulty in Scotland or Ireland.

Mr. Wakley said he would be contented if others were. He explained the circumstances of the meeting whose objects to his own astonishment he had misunderstood, but he had seen no violence at the meeting, because of his great difference with them. He was for enfranchisement in the college, and so were two-thirds of the meeting. Now, by this measure a person at 22 years of age was declared to be perfectly qualified in every branch of medical science; but at 26 something curious had happened; during the progress of his experience he had lost his medical information, and was only to rank as a surgeon. Was it practicable to carry out such an arrangement? He trusted that the Right Hon. Baronet would see the absurdity of it, and would not adhere to a system so unreasonable.

Sir J. Graham advised the hon. member to reserve his vituperation in regard to the bill, to be sent forward to the public through some other vehicle; it would not have much effect in that house. The hon. member himself admitted that at 22 a young man, undergoing a strict examination, was perfectly qualified to practise; well, after four years practice, and experience in his profession, at the age of 26 he was to be admitted,—after a second examination of a higher character—one of greater strictness—he was to be admitted as a fellow of two colleges, composed of men who have the highest character in the medical world in Europe. Yet this was the plan to which the hon. gentleman applied the vituperative epithets of absurd, patchwork, indefensible, nonsensical. He did not care two rushes for such terms from the hon. gentleman, as he (Sir J. Graham) had learned as well as he that hard words broke no bones.

Mr. Hawes could have brought documentary evidence to shew that Mr. Wakley's disparagement of the National Association was ill founded. Four thousand members unanimously supported that body, and the Bill, with exceptions in detail, would doubtless meet their approval.

Mr. Wakley apologized to Sir James Graham for the abusive epithets he had applied to the Bill; he intended no personal offence.

The Bill had passed through committee *pro forma*, and was reported to the House with some verbal alterations. It will be re-committed on Monday, June 9th.

The Charters' Bill went through the same ceremony, and is to be re-committed also on the 9th of June.

Royal Medical and Chirurgical Society.—The following are the titles of the papers to be read at the meeting of this Society on the 13th inst.:—"Constitutional syphilis in the father, inducing repeated abortions, and subsequent infection of the fœtus born at the full period, the mother remaining wholly free from disease," by William Acton, surgeon to the Islington Dispensary.—"On the Use of Creosote Injections in Camp Dysentery," by T. Branston Wilmot, M.D.

Royal College of Surgeons.—The Jacksonian prize has been adjudged to Edwards Crisp, Esq., of Walworth, for his essay on "The Anatomical Structure and Diseases of the larger Blood Vessels."

No. 295 **SUMMARY.** May 17.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

I yesterday mentioned that in epilepsy attempts had been made to remove the structural disease by trepanning, and we have now to consider what is best to be done besides the measures already mentioned. I have already described the remedies for those particular conditions of the circulation, and the irritations existing in the system which bring the structural disease into operation; and that means should be taken to equalize the circulation of the blood, to diminish the plethora on the one hand, and the state of anemia on the other; and again, in the intermediate class, to prevent the tendency to local determination of blood, which is of habitual occurrence. Coldness of the extremities is a predisposing cause to determination to the head. Yesterday I saw a gentleman who had a violent attack of epilepsy, which was first brought on in connexion with habitual coldness of the feet and occasional violent exertion. I put him on aperients, warmth to the extremities, cold to the head, and various tonic measures to promote the equality of the whole circulation. In other cases a different kind of treatment is required; where there is plethora, the treatment is to be judged of by the condition of the pulse, and the warmth of the various parts indicating bloodletting; and in the opposite state by the extreme coldness of the extremities, in which the treatment should be of the tonic and supporting kind; always endeavouring in these cases to equalize the circulation. The excretions are apt to become defective from irregularity in the circulation, and these require to be assisted by the various remedies used for that purpose. Besides the tonics I have mentioned, metallic tonics are found to be of peculiar efficacy in these cases; the nitrate of silver, the sulphate of copper, and the oxide and sulphate of zinc. These have a good effect in cases where there is much weakness of the system and a tendency to coldness in the extremities. Nitrate of silver may be given in doses of one grain gradually increased up to six grains, three times a day, and this may be continued for six weeks or two months. I have known this treatment to be very efficacious in suspending the attacks. In giving nitrate of silver there is a fear of dyeing the skin black or blue, but it has been lately found out that iodide of potassium will remove that; and Dr. James Johnson says, he has given the remedy for two months at a time without any such effect. It is only where the remedy has been given for above the period of three months that the dyeing effect ensued. No medical man would exhibit it for that length of time, and six weeks at a time is quite long enough; its use being reserved for a future time. The sulphate of copper has been found useful in some cases, but it irritates the stomach. In asthenic and anemic cases, iron in its various preparations has been found signally useful, and perhaps no medicine is so effectual in restoring the condition of the blood, and equalizing the circulation. Iron, however, has a tendency to diminish the secretions, and this renders it necessary to watch its operation. The efficacy of all these things depends on their restoring equality and vigour to the whole circulation. In a few cases it is said that some vegetable tonics have been useful, but they are not by any means to be compared with the metallic ones. Somehow or other metallic tonics very remarkably improve the tone of the vascular system, and diminish the susceptibility of the nervous system, in a way that I cannot explain, but it is a practical fact of great importance. There are, too, antispasmodic remedies that are useful in dispelling the wind, and relaxing the spasmodic affections in connexion with the alimentary canal, but they are of little efficacy as remedial measures. Turpentine may be excepted from these; it is signally useful in some forms of epilepsy, chiefly connected with intestinal disease. Indigo has also been found useful in some cases of epilepsy; it is an empirical remedy, but it acts as a tonic, and may be given in doses of from ten grains up to two scruples, three or four times a day. There are some peculiar cases in which special remedies are found useful. In epilepsy brought on from blows on the head, mercury and iodide of potassium are effectual remedies, and this last remedy has been particularly useful in cases of disease of the sphenoid bone, accompanied by discharge from the nose. In all cases it is proper to use those measures which tend to diminish nervous irritability and susceptibility, or moral and mental excitement. Exercise in the pure air as much as the strength will bear, without its being violent, and the use of the vapour bath are remedies that improve the tone of the circulation.

Catalepsy is to be taken together with epilepsy. In this disease there is a suspension of consciousness, partial or complete, and a suspension of voluntary motion; but the muscles have a certain degree of tonic contractility, so that they can be fixed in any position in which they are placed without change, while the patient remains perfectly still and immobile. This seems to be a sort of paralysis of sensation and of voluntary motion, without a removal of the excito-motory power. When a limb is raised it falls down from want of power, and in whatever position the limbs are placed, they retain a spasmodic rigidity. Catalepsy is met with in hysterical and epileptic subjects, and is known to be produced after very serious moral emotions. The person affected becomes like a statue, or only partially mobile: the eyes open or shut, and the pupil, though contractile, is commonly dilated. The respiration suffers little change, and this condition may last some minutes, or many days; the recovery from the fit is commonly sudden, without any consciousness of what has happened. There is a condition something like this, in which there is loss of power of motion, but still some consciousness is retained; this is a state of trance, in which persons have been supposed to be dead, and have been nearly buried alive. Sometimes persons are seized with an affection resembling catalepsy, in which they sing in ecstasy, and laugh, the body continuing immobile, while the consciousness of thought is wrapped up in one engrossing topic. This partakes more of the character of mental derangement.

Catalepsy and its conditions may result from opposite states, just as epilepsy may; from fulness in the vascular system, after excessive depletion, and in some states, from serious disease of the brain, ending in coma. Generally speaking, little is to be thought of these kind of things in females, as to any serious results. Catalepsy is a kind of thing which some persons simulate; there have been cases of impostors resisting all sorts of trials. A case is recorded of a conscript, who, being anxious to get discharged, so successfully simulated this state that he obtained his object, and was the next day walking about as well as ever. The most successful way of discovering these cases is to try the moral impressions, and observe the state of the pulse, which may be taken as an index of the mind; the pulse is not always under the control of a person, and if he were to hear you prescribe for him, in sober serious language, a red hot iron to be applied to his back or some other sensible part, you would soon see whether he was feigning. Trying whether the person will wink by flashing something before the eyes is another means of detection. It is not a matter of any difficulty to distinguish extreme cases from death. I have never met with an extreme case of this kind, in which the sounds of the heart were not audible. The treatment of catalepsy is on much the same principles as that of epilepsy. In connexion with plethora, bloodletting, or cupping may be used, and cold water dashed on the head and the back of the neck, and in most cases purgatives, croton oil, and turpentine are useful.

Delirium tremens is an affection of the sensorial and motory functions, and is sometimes called the brain fever of drunkards. There are two kinds of this affection, which, practically, it is important to distinguish. It may be phrenitic, accompanied with a flushed face, suffused eye, pulse quick and full, or hard, and the skin hot. It arises from excessive intoxication in persons, not perhaps accustomed to drink to a great amount. It is accompanied by tremor and excitement, and is to be distinguished with regard to the mode of treatment from the other kind of delirium, or the nervous delirium tremens, which is, perhaps, of more common occurrence. This kind of delirium occurs in the more nervous persons; there is pallidity of the face, and the surface is cool, and wanting the flush the other presented; the pulse is often at first slow, and afterwards it becomes quick and rioting. This arises not from temporary intoxication, but from habitual excess. There is a loss of appetite, and the patient dreams much at night, or there is wakefulness, and giddiness, tremor of the hands, gradually coming on; there is depression of spirits, a feeling of weight and oppression, and a peculiar anxiety about his affairs. These are the premonitory symptoms. The second stage is marked by the occurrence of

delirium, and this is manifest, first, by much excitement, and anxiety about something to be done; the temper is very excitable, and distressed; the pulse is quick, frequent, and small, from 100 to 120; the skin is cool, and covered with a clammy, fœtid perspiration, smelling, it is said, like garlic; the tremor becomes very distinct; the evacuations, which were usually very slimy, and dark, and thick, resemble whitish slime; there is restlessness and agitation; the eyes are distended, and move too and fro; the features bear the stamp of suspicion, and sometimes of terror. He speaks of monsters persecuting him; yet when not irritated, he will answer questions, and then relapse into a state of delirium; he will explain his feelings, and his engrossing thoughts. The pupils are commonly contracted, but there is no intolerance of light, and this is a remarkable difference between phrenitic delirium and phrenitis itself. The patients in this condition, too, are not commonly violent, and if any violence is observed, it is only when they are opposed or restrained. The symptoms may go on and terminate in exhaustion and death, if sleep do not ensue, in which case the patient may recover from the attack. In bad cases there is sinking and increasing coldness; the pulse is more thready and weaker; there is a catching of the bed-clothes, and great perspiration of the clammy and fœtid kind, and there is a gradual sinking, still accompanied by itchings. On examining the bodies of persons who die of this disease, there is rarely anything particular found in the head. In most cases, the chief disease is found in the stomach and the liver. In the other cases, accompanied by more or less phrensy and excitement, the patients have sometimes died with symptoms of arachnitis. Arachnitis and meningitis are apt to be the termination of delirium, caused by excessive drinking in persons not accustomed to excesses of liquor. The exciting causes are habitual excesses of intoxicating liquors, which may act in two ways: it may upset the functions of the brain, by causing a great degree of inflammatory excitement, and determination of blood; or, on the other hand, it may arise from continued stimulation, and excitability of the brain, which goes on until exhaustion of the vital functions ensues. Under these circumstances, the effect sometimes arises in a most remarkable manner. When the continued stimulus to which the patient is accustomed is withdrawn, there is instantly nervous excitability created. It sometimes arises from other poisonous influences besides those of alcohol. Opium-eaters are subject to the same thing, on the suspension of their indulgence. Great mental excitement and anxiety may cause a very similar affection, and it is apt to occur after great surgical operations, and after child-bearing. In all the the conditions in which it occurs, there is weakness of the pulse, absence of the flushed countenance, and the appearances of inflammation. However, inflammation may sometimes supervene, where there is an early development of the disease in persons of plethoric habit, and even in other cases, as a sort of re-action.

The prognosis of delirium tremens will be favourable in the first attack, but when the attack occurs again, the effect is more serious, arising from excitement of the brain. The distinction between delirium and phrenitis is important; there is an absence of continued heat of skin, the dryness of the skin, the absence of intolerance of light; in all the weak and nervous cases, the extreme fulness of the pulse; the countenance, instead of being fierce and excitable, as in phrenitis, exhibits a peculiar kind of suspicion and anxiety. The treatment is different in the two cases I have adverted to; in persons not accustomed to drink, or robust persons who have indulged to excess, and who have brought on the attack with more or less tremor, accompanied with flushing of the face, suffused eyes, rubbing of the hands, &c,—in this case leeching, cupping, calomel, and so forth, are the measures indicated; according to the state of the pulse and the general symptoms. After these remedies have been applied, they should be followed up by remedies to procure rest and sleep, opium, and so forth. The amount will vary from one to three grains, increased, if necessary, up to five or six, or even more grains. In some cases fifteen or twenty grains have been given every two hours; generally speaking smaller doses would answer. Purgatives should be given at the same time to get rid of the bad secretions of the alimentary canal. In cases where there is increased force of the pulse and increased fulness, with a tendency to flushing of the face, it is well to combine opium, with a small quantity of tartar emetic; and in the opposite state where there is great pallidity, and the pulse is very small, stimulants should be given; this is more important than the exhibition of opium. Where opium has prostrated the powers, ammonia, ether and brandy and water will be useful: the narcotic influence of opium will reduce the heart's power, or stop the spinal functions, so that respiration ceases. This is a point that has not been sufficiently attended to. I have seen cases in which it was more important to begin with stimulants than opium itself. Where there are symptoms of extreme exhaustion, we must stimulate at the same time that we give opium. It is of great consequence to give nourishment as well as stimulants: as soon as sleep is obtained, the cure may be pronounced to be certain. A return of the inflammatory symptoms may occur, and this requires fresh treatment, and the opium to be continued.

Paralysis agitans, or shaking palsy, occurs in convulsive diseases, in which there is no loss of consciousness, nor disturbance of the sensorial faculties; and it must be supposed that under these circumstances there is some irritating cause to excite the motory parts of the brain. However, when the sensibility is exalted, as in hydrophobia and hysteria, in the long run the mental faculties do not suffer. It is a very obstinate affection, and has not been traced to its real source. Slight degrees of palsy or tremors are seen among persons whose constitution is weak, particularly when excited, and this seems to consist in a want of power to steady or control motion, and may be referred to the tone of the muscles. The same thing is seen after habitual excitement of the nervous system by stimulants. The trembling of drunkards seems to be of this kind, and that of opium-eaters, too. The disease is sometimes partial, and sometimes general. There are cases in which particular limbs only tremble, without any other part of the body. In some the tremor comes on at particular periods. The bad cases are those in which it may continue during the day, and in the night during sleep; and one of the most common causes of this is the long continued use of mercury, arsenic, and copper. The effect of these metallic poisons may be merely temporary, but sometimes it is permanent. In these cases the great object is to restore the tonicity of the system if possible, and to use every method to get the offending matter out of the system.

COURSE OF LECTURES ON SKIN DISEASES,

By D. J. CORRIGAN, M.D., Physician to the Whitworth, Hardwick and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

There is another form of scarlatina anginosa where purulent matter is discharged in abundance from the fauces, pharynx, and nares; at least the secretion from these parts, copious and fœtid, possesses all the characteristics of odour, colour, and consistence of pure pus. Here the plan of treatment recommended for the diphtheritic variety of scarlatina anginosa will be required.

We now come to consider scarlatina maligna. Here the ulcers on the throat often take on a sloughing action, and from this cause life is frequently lost. In other cases we frequently find death occur in twenty-four hours after the poison of the disease has been imbibed, while the patient possesses perfect mastery over his senses.

What is it that kills here? It is the shock of the poison, which debilitates the constitution to such a degree, that it cannot rally, and life in a short time becomes extinct. We know that the absorption of the poison can do this, but how the poison operates in its work of death, we do not know. In such cases the patient does not possess sufficient vigour to oppose successfully the onset of the disease. Re-action never sets in, and he dies of the directly debilitating effects of scarlatina at its onset. I have often seen persons in this state admitted into the Whitworth Hospital, who, in perfect possession of their senses, while sitting on the side of their bed, have talked to me of their state rationally, and in an hour after I have seen them dead. In such cases the pulse at the wrist becomes extinct, it can no longer be felt, the action of the heart is almost suspended, the skin feels cold and clammy; in a word, the patient is all but lifeless. Here I think we often can be of service. Our first step should be to place the patient in a warm bath, heated to 100° or upwards, in which he should be allowed to remain until general redness of the surface ensues, and the pulse can be felt beating at the wrist with some degree of vigour. With what view do we place a patient in such a situation in a warm bath, and allow him to remain there until the skin becomes reddened and the pulse quickened? The reason is obvious. We do it to remove the venous congestion of the surface, by imparting the stimulus of heat to the debilitated capillary circulation of the skin. We know it is probable (indeed not probable, but certain) that the stimulation set up in the vessels of the surface, is also exerted in the capillaries of the internal organs, and that the circulation throughout the whole system is thus excited to greater vigour. It is in this form of scarlatina that the eruption becomes irregular in appearance, coming out for a day or so, then disappearing, and showing itself perhaps after an interval of six or eight days. Here the eruption is most vivid on the hands and legs, and scarcely or not at all visible on the face or trunk. What is the reason of this, or why should the appearance of the eruption be reversed here from that of scarlatina simplex. In the latter the eruption is most intense, and thickest on the face and the other parts of the body which are best defended from cold, such as the axillæ, loins, flexures of the knee, and elbow joints; while here the very reverse takes place; the eruption appears most on these parts of the body which are most exposed to cold. We find the reason of this seeming paradox in the greater degree of congestion which prevails in the legs and hands. Among the stigmata of this form of scarlatina we often find intermixed spots of purpura hæmorrhagica; we also see them on the inside of the fauces, along the soft palate, and on the posterior pharynx, from which situations hæmorrhage often takes place. Having roused the circulation by the warm bath and other stimulants, your next object should be to keep up this increased action if you can. For this purpose, bark in combination with ammonia, quinine with wine, and strong nourishing animal soups are among the best means you can employ. In the treatment necessary for this form of scarlatina, you find a confirmation of the principle so often laid down during these lectures, that diseases bearing the same name, may require plans of treatment diametrically opposite. You see this exemplified in the different forms of fever; some requiring wine, others mercury, and others again, leeches and opium. In the inflammatory form of scarlatina we find cold of incalculable utility in checking the progress of the disease. Use it here, and you will at once kill the patient subjected to its agency. These facts, in place of strengthening the doctrine of homœopathy, as they would seem to do at first sight, on the other hand, afford incontrovertible proof of its untenability.

Having finished the subject of Scarlatina, we next come to urticaria, or nettle rash, with which you are all familiar. On this subject I shall make but few observations. This eruption generally appears in persons whose skin is extremely irritable and susceptible of every source of irritation. It makes its appearance with some degree of fever, in patches of livid red, which you might mistake for scarlatina; in these patches, you will find minute white elevations of the cuticle (known to all of you under the name of hives,) above the surrounding surface, giving the whole an appearance well exemplified in the plate (handing it round). How these minute elevations of cuticle are produ-

ced, we may conjecture, namely, by an inflammation of the cellular tissue beneath the skin, which throws out serum. But why these particular spots should be selected for its disposition, we cannot guess with any possibility; we know no more, than that these vesicles exist in these situations. These hives, as they are termed, when coming out, excite some degree of fever, and great irritation, and the itching which exists in them is very distressing. In persons of very irritable skin, and who are subject to hives, you can produce at pleasure, figures of any determinate form, For this purpose, all you have to do, is to get a door-key, or pair of scissors, and press it upon the cuticle, or even to write on the skin with any blunt instrument; after a few seconds, you will find the skin becoming red to a certain extent around the part which has been pressed or written upon, and in the centre of this redness, you will have an elevated white patch, of the exact figure of the key or scissors, or of the letters which have been traced upon it. There is another form of urticaria, which is produced in consequence of having eaten shell-fish which has been long kept, or which has been fed on food of a poisonous nature, at present unknown to us. To such an extent does this latter cause exist, that the shell-fish gathered on some coasts, as you all know, are completely unfit for food, and consequently, are never eaten. Indeed the shell-fish gathered off our own shores sometimes produce this kind of urticaria; and I can well recollect a case where a gentleman, a friend of mine, was affected with it in consequence of having eaten some lobsters. In about two hours after having used it, he was attacked with violent pain of stomach and diarrhœa, when the rash in question made its appearance. The rash itself soon wore away, but of the gastro-intestinal irritation set up by using the poisoned food, he never completely recovered. Many years have now rolled by since it first attacked him, and he still suffers from it occasionally. In all these cases of urticaria, the gastro-intestinal irritation is a cause of very great annoyance, and very often is extremely difficult of cure. Common sense will immediately suggest to you in such cases the treatment which you should adopt. Administer an emetic to rid the stomach of the offending matter, and a dose of opium given subsequently will prove of infinite advantage in allaying the irritation which exists along the disordered alimentary mucous membrane. And according to the known aphorism —"sublatâ causâ tollitur effectus," when this irritation is lessened, that of the skin will be sure to share in the benefit. Gentlemen, this concludes the subject of the exanthemata; we next come to the second class Vesiculæ, comprising the following orders:—

MILIARIA, ECZEMA, HERPES, SCABIES.

From the class "Vesiculæ," I have thought it proper to remove Varicella, or Chicken-pock, for reasons which I shall mention hereafter. By a vesicle, you are aware, is meant an elevation of a portion of cuticle from the true skin beneath, filled in the first instance with fluid of a clear character, afterwards becoming turbid, and finally ending in desquamation, unless by some external cause this natural termination be prevented or altered. Some of these, as herpes, run as determinate a course as any of the exanthemata, small-pox for instance. The first of these, Miliaria, has been set down by Wilson and others as an idiopathic disease. But this is an error; it never appears as a disease, *per se*, but invariably accompanies those which have been mismanaged during their progress, or else it waits upon others sympathetically.

Miliaria consists in the appearance of minute vesicles, filled with clear fluid; this becomes whitish, and afterwards turbid, finally ending in desquamation. When this has continued for any length of time, we find the parts which have been the seat of the eruption presenting a red shining appearance, owing to the minute furfuraceous incrustations which formed when the vesicle dried, having fallen off, and left the skin in the state just mentioned. At the first coming out of these vesicles you would be inclined to overlook them altogether, as the fluid contained in them is so clear, that you can, as it were, see through them. However, if you look at them sidewise you will distinctly perceive their vesicular character. In cases of this disease there is not the least ground for belief that it ever is idiopathic. We find it in phthisis when the colliquative sweats are running the patient down fast; we find it in pneumonia, in gastro-enteritis, in abscess of the liver, and, in fine, whenever the disease, no matter what it may be, has been aggravated by the injudicious employment of a heating regimen. In treating this affection, the only thing necessary for you to inquire into as to its cure is, what has caused it? If it has arisen from the application of too much heat to the skin, causing great perspiration (and perhaps it may be caused by the skin refusing to allow the sweat to transpire as fast as it is secreted), the means of cure will readily present themselves to you, by lowering the temperature of the patient's body to the natural standard. If it has arisen in consequence of some unaccountable sympathy between the skin and the organs affected, as in hepatic abscess, pneumonia, &c., your efforts for its removal must be directed to the cure of the disease of which it is sympathetic.

The next in order is eczema. This is a disease which is met with in the acute and chronic forms. The place where you most frequently meet with cases of this affection, is the dispensary attached to a surgical hospital. A man tells you that he has a sore leg; he strips down his stocking from one, or perhaps both, legs, and you will find their anterior surfaces (generally the affected parts) red and inflamed, and over them are scattered numerous indentations, from each of which you can perceive, with the naked eye, a drop of clear fluid welling out. These minute indentations have been the seat of the eczematous vesicles, which having been broken, the fluid in them dries, and forms a scab or crust, underneath which the fluid still continues to be secreted. In ninety-nine cases out of a hundred of eczema, you will find soothing applications productive of most benefit to the patient, and serve best to control the inflammation. There is a variety of eczema which appears in the head, at the roots of the hair. When the vesicles break, the fluid contained within them dries, and gives rise to a peculiar state of the head, to which the term "scald" has been erroneously applied, and which Alibert, from the fortuitous circumstance of colour alone, has made a new disease of, under the name of "silvery tinea." It is not tinea at all; it is nothing but a form of eczema, produced by neglect of cleanliness of the head, and is quite unworthy of the honour of a separate name given it by Alibert. (Sending round some plates of Alibert's.) Here you perceive the appearance which the head presents when affected with this form of eczema. This eruption is also apt to appear on the back of the neck, and behind the ears, extending towards the jaw, in children of a scrofulous habit, more particularly among those of the upper walks of life. It comes out in minute vesicles, filled with a clear fluid, which gradually grows turbid; these vesicles are attended with severe irritation, and their duration is apt to extend over a great period of time. The hands of grocers and bakers are liable to a variety of eczema, which sometimes is mistaken for scabies. Here the vesicles make their appearance along the back of the hand, on the wrist, to the ball of the thumb, and thence to the space between the fingers. In this variety, the vesicles on the back of the hand, and in the other situations present a character after a little time quite different from that of scabies; they dry up and form crusts, through which rhagades or splits soon make their appearance. A mistake if committed here between both diseases would lead to an injurious line of practice, and the opinion delivered by you would be anything but agreeable to the patient. There is another variety named Eczema Impetiginodes (the connecting link, as it would seem, between vesicular and pustular diseases) where, from long continued irritation, the vesicles have taken on the action of secreting pus. Here we find scabs mixed with the scales. (A very excellent drawing of this disease attacking the fore arm and back of the hand was here exhibited, which has been taken from a case which he had for a length of time in the Whitworth Hospital.) In this case the remedies from which most benefit was derived were, the lotio plumbi acetatis, constantly applied over the affected parts, and an ointment composed of emplast. lythargyri melted, and thinned down with almond oil. In all the varieties of this disease, as I have before remarked, you will derive most benefit from the use of sedative remedies applied to the parts. These observations apply equally to that form of it which attacks delicate children. As to that where it appears in grocers or bakers, and to the more unmanageable form of Eczema Impetiginodes, of this class of remedies, those which, from experience of their efficacy, I would be inclined to recommend for your adoption, are the ung. cerussæ, or the lotio lythargyri acetatis diluted.

In this disease you never can apply successfully to practise the well known law of removing local irritation by the application of a greater stimulant. This you never can venture upon here. If ever you should be tempted to use a stimulant here, let it not be stronger than the lotio nigra, or the ung. citrini considerably diluted with lard. In the treatment of these varieties of eczema it will facilitate very much the cure, if you would apply over the fluid applications or dressings a piece of oiled silk large enough to cover them, in order that an equal temperature may be kept up by the heat generated in the part. This, combining with the moisture of the lotion, will form an application highly agreeable to the feelings of the patient, one of a very soothing character. I trust you will forgive my tautology, when I here again repeat, that in treating all the various forms of eczema, you will derive more benefit from remedies of abundantly soothing nature than from the use of those of opposite properties.

Next, in the class of vesicular diseases, stands herpes. This, in one or other of its many forms, must be familiar to you, as instances of it must have come under your notice from time to time. The form of herpes which is most commonly met with is that called herpes zoster or St. Anthony's fire. Its progress is as follows:—The person on whom this form of herpes is about to appear, feels languid or listless for two or three days previously to the eruption appearing; with pains darting through the parts on which it is about to shew itself, which situation is generally on the trunk below the breast: these pains are of a very distressing nature, and convey a sensation as if the parts had been scalded. They continue with more or less severity during the disease. The pain naturally leads the patient to examine the part, when he finds it inflamed and vesicles making their appearance on the cuticle. This inflammation of the skin is accompanied by inflammation of the subjacent cellular tissue, to which are probably owing the deep-seated pains which prove so troublesome during the disease. On or about the ninth day from the commencement of the illness, these vesicles begin to dry up, and are completely detached by about the fifteenth day from its date. In the country, where this form of herpes is oftenest met with, there runs a belief that if the eruption surround the body it is surely fatal. Of the absurdity of this belief I need not attempt to convince you. It is probably founded on the infrequency of the occurrence, for cases are rarely met with where this eruption has surrounded the body. The only disease with which we might confound this is eczema; but an attention to the following points of discrimination will always enable us to decide in any case where we might be doubtful of the disease before us. Herpes exists in an acute form. In the class "vesiculæ" you will find but two diseases which ever become chronic, namely itch and eczema. What I mean by "acute" is, that the vesicles run through their course quickly; the skin becomes inflamed; serum is thrown out beneath the cuticle; this serum, first clear, afterward becomes turbid, dries up, forms a scale, which falls off, leaving the skin beneath of the natural texture and colour. In these cases no irritation of yours or that you can employ will serve to reproduce them; nothing will do this short of a reapplication of the primary exciting cause, whatever that may be. In eczema,

when the crusts are removed by poultice or other application, the case is quite different; here you find the red surface underneath, secreting the peculiar fluid which had previously formed the scale, and this fluid continues to be secreted for a very great length of time, unless proper means of cure be adopted. Again, in herpes you find the eruption preceded by slight fever of two or three days duration, accompanied by more or less derangement of the digestive organs, with deep-seated burning pain in the part where the vesicles are about to appear, these being always defined and separate from each other, in clusters assuming somewhat of a semi-circular form, attended with inflammation of the subcutaneous cellular tissue. And finally, this eruption occupies a determinate period of time in going through its several stages of premonitory fever, eruption, maturation, and decline. All these will render the diagnosis between it and eczema anything but difficult.

The treatment here consists in giving at the onset, purgative medicine, to clear out the alimentary canal, and should the vesicles be by any cause broken, in applying the aq. lytharg. acet., made very dilute, and in the event of their proving very painful, in fomenting them with tepid decoctum chamomeli. The disease in general, is one not requiring treatment of any kind; care need only be taken that the vesicles are not broken. The eruption, as I have already remarked, terminates in twelve or fifteen days from its appearance. Herpes is not confined to the trunk alone, but it may attack any part of the body, such as the eyelids, the scalp, the prepuce, or the labia pudendi in women, and it is frequently met with on the lips, when the persons on whom it appears, generally attribute it to the " breaking up of a cold."

Herpes appearing on either of the latter situations, the prepuce, or labia, may be mistaken for chancre. This, for many reasons, would be a sad mistake to commit. Firstly, the remedies applied at the commencement for the cure of chancre, generally those of a caustic nature, would be wholly unfit for the treatment of herpes. Secondly, such an opinion, if acted upon, might, under peculiar circumstances, be the means of producing lasting dissension and unhappiness in a family; and thirdly, by such a practical error, your own character would be sure to suffer. Here, the application of caustic would give rise to ulceration very difficult to manage, and tedious in its cure. Herpes in these latter situations, makes its appearance with an itching of the parts; if on the prepuce, this becomes somewhat swollen from inflammation of the cellular tissue. If the part be now examined closely, a cluster of minute white vesicles will be seen making their appearance; these continue for a few days, when they are absorbed, and disappear, leaving no trace of their existence behind. From chancre they will at once be distinguished by wanting the hardened edge and base of the latter, by their never attaining any progressive increase of size, and by disappearing *sua sponte* in a few days, if left to nature. Greasy applications considerably disagree with these vesicles, and, like caustic, are apt to change them into lingering sores. Another effect of applying irritating, or improper dressings to herpes, is the appearance of buboes, from the irritation extending along the absorbents of the part to the groin; even the presence of a bit of lint between the glans penis and the prepuce will be quite enough to excite irritation; the only thing for you to prescribe, is frequent ablution with a tepid lotion of aq. lytharg. acetat. very much diluted. At the commencement of fever of a gastro-enteritic character, where the mucous membrane of the stomach and bowels becomes affected, herpetic vesicles are apt to appear upon the lips. These betoken a favourable issue to the disease, if they go on regularly. In pneumonia, these vesicles make their appearance also towards its close. In this latter disease, if, instead of becoming well-defined, and full, these vesicles become flat, and fluid, or if, in place of being filled with the proper serum, they are seen tinged with a red or black fluid, they denote an unfavourable issue. The black colour of the vesicles depends upon the effusion of blood with the serum, which gives the whole, the blackish tinge referred to. In every case, when this termination of herpes takes place, death is almost sure to occur; at least nine out of every ten such cases prove fatal. There is a form of disease attacking the lips, to which the name herpes has been erroneously given. It is not herpes at all, but a form of psoriasis, which is exceedingly difficult of removal; the lips, sometimes the upper, sometimes the under one, and frequently both, become red, thickened, scaly, puckered, and fissured.

LECTURES ON COMPARATIVE ANATOMY,

Delivered at the Royal College of Surgeons of England, during the Summer Session of 1845,

By Prof. Owen, F.R.S.,

Professor of Comparative Anatomy, and Conservator of the Museum to the Royal College of Surgeons of England.

Professor Owen, in commencing on Tuesday last a course of twenty-four lectures on the organization of the invertebrate animals, compared in the ascending scale according to their classes, observed,—that he had been in the habit of preparing a written lecture, as introductory to the course he was about to deliver, but on the present occasion he had been prevented doing so, by having had a task recently assigned him, the performance of which he trusted would be much more useful than the most carefully prepared general lecture. The task consisted in preparing a general synopsis of the whole contents of the two musea belonging to the college,—a task involving attention to a great many details, much more so than had been anticipated, and requiring so much time, as to render it impossible for him to prepare a written introductory lecture, except by the postponement of that work, which he was happy to say he had that day completed.

Mr. Owen then referred to the great importance of a perfect knowledge of anatomy, and congratulated the members of the medical profession, that they were required to enter upon their studies by the portals of anatomy, and compared their good fortune in having so highly interesting a science for investigation with that of the clergy and the members of the legal profession, whose initiatory studies are of a comparatively dry and uninteresting nature. He (Mr. Owen) considered the study of the mechanism of the human frame as the highest object of science. He then alluded to its great utility to surgeons, and observed that the great success which Dr. Baillie met with in practice was mainly attributable to his practical acquaintance with anatomy, as compared with that of those physicians who were cotemporary with him. He next alluded to the effect produced by the progress made in the study of anatomy in the discovery of the physiology of circulation. It was the discovery of the existence of valves in the veins by Fabricius ab Aquapendente, that led Harvey to his great discovery of the mode in which the circulation is carried on. Human anatomy alone, however, is insufficient to teach the use of the different parts of the human frame, and it is a question whether Harvey would have been able to push his discoveries much farther than his master had done, had he not carried on a series of enquiries into the structure of the lower animals—the knowledge which he thus obtained enabling him afterwards to verify his opinions by instituting experiments on them.

Comparative anatomy is of use by enabling us to perform experiments on the lower order of animals, which we are not in a position to perform on man, and to witness such operations performed, as it were, by Nature herself. Let us take, for example, the organs of generation, which in man are exceedingly complicated, consisting of the testes, vesiculæ seminales, prostate, Cowper's glands, &c. It may be said that here we have no need of comparative anatomy to assist us in determining the use of these organs, for if castration be performed, the generative power is lost, but this is by no means conclusive, because, if it were possible to remove in man, without obliterating the *vas deferens*, and without injury to life, the vesiculæ seminales, the prostate, and Cowper's glands, the person experimented on might also become impotent, so that it might then be asserted that the most important part of the organs of generation were lost. This abstraction of parts, which, if it were possible to do it, would produce such a result in man, is effected by nature in different animals, some of whom are void of vesiculæ seminales, others have no prostate, and most have no accessory glands at all, etc. This application of comparative anatomy will give the most clear idea of the use of different organs of the body. Mr. Owen then made especial reference to the experiments of Sir B. Brodie on the influence of innervation on digestion, and on the biliary ducts, &c. as illustrated by comparative anatomy; and to the still more brilliant experiments of Sir Charles Bell, which having been performed on mammalia, were, therefore, by some deemed unsatisfactory, until it was shewn that the anterior and posterior roots of the spinal nerves were longer and better separated in the frog, which being a cold-blooded animal, was also better adapted for these experiments, and the discovery was fully confirmed by Muller.

There are many parts in the lower order of animals which bear a great resemblance to the corresponding parts in man. Human anatomy, therefore, is not to be regarded as distinct, but as forming part of a more extensive science. When human anatomy was first investigated, it was done in a sort of absolute manner, as distinct from all other sciences, and its nomenclature was in a degree arbitrary, so that at present it would not be possible to trace the origin of some of the names. In the same manner the necessity was felt of being acquainted with the structure of the lower animals by those who devoted their attention to the treatment of their diseases, but they pursued it in a manner irrespective of human anatomy, and remote therefrom, and the nomenclature was applied to the anatomy of the horse in a similar manner. It is known, however, from the study of arbitrary comparative anatomy, that the parts of different species of animals have a certain degree of correspondence with each other—it was found that the fore-knee of the veterinary surgeons corresponded with the carpus in human anatomy; the *common bone* with the metacarpus, the *great pastern* with the first phalanx, the *small pastern* with the second phalanx, and the coffin bone with the third or ungual phalanx. The splint-bones of the horse were rudiments of undeveloped metacarpal bones, the hoof serving in lieu of the nail, by which the human fingers are terminated. By the best modern veterinarians, and especially on the Continent, therefore, those parts are all called by the same name as in human anatomy, and observation has there led to the formation of a scientific nomenclature.

By carrying the enquiry further, and examining the paddle of a whale, it will be found on stripping off the integuments, that there is a bone corresponding to the humerus; in the next segment there are two bones, which correspond to the radius and ulna, and there also will be found the carpus, metacarpus, and phalanges. The same remarks apply to the cold-blooded animals, and are exemplified for example, by the paddle of the turtle. The same correspondence obtains throughout the whole frame, modified only by excess or deficiency of development. The resemblances and analogies which are thus traced in the adult become much more marked and striking, if the human frame be considered in its unfinished or embryonic state, and compared with the full-grown animal. This is shewn by the fœtal skeleton,—by comparing the skull of the fœtus separated into different pieces formed by the respective points of ossification: for instance, the four pieces of which the occipital bone is composed, bear a strong resemblance to the corresponding permanently separate bones in the crocodile and codfish. We find, also, corresponding points of resemblance in the same organization, although at first sight they may seem to be different. The vertebræ of the fœtus shew a resemblance to the occiput, the distinct ossification of the body answering to the basilar process, and the separated pieces forming the sides of the arch, to the other portions of the occipital bone, more especially as at that period of life there is no

spinous process developed. This series of resemblances leads to another between undeveloped higher organisms and mature lower organisms, are still more interesting than those obscured by comparing the frame-work of different fully developed an male, and, when duly defined, will lead to the establishment of a most important generalization in anatomical science, whereby we shall be enabled to understand a great number of facts, which otherwise we could not comprehend.

Proceeding thence, the points of resemblance between the existing animals and those which are now extinct were considered, and Mr Owen stated that a knowledge of the habits of the existing species gave the comparative anatomist the power of reconstructing, it may be, a lost species. Take for instance, the phalanx of a horse,—it is evidently adapted for pressure only, and not fitted for either lacerating a living prey or climbing, it showed, therefore, that it was not dependent on other animals for its prey or means of existence, but possessed the power of locomotion from one pasturage to another. The teeth, the jaws, the skull the digestive organs, the whole system, are modified in subserviency to such food and mode of life, as are indicated by the single bone. For this application of facts we are indebted to the great Cuvier. Mr Owen then referred to the condition of the tertiary formation of the earth, in the first and second strata, the diluvium and pliocene, and the remains of mammalia in those strata, and mentioned the remains of those animals which are found in those strata in England, especially in the caverns of Devonshire, among which he enumerated the wild oxen, mammoth rhinoceros, hippopotamus, hyenas, tigers, &c, with strange forms of carnivora of one of which he exhibited a powerful canine tooth, possessing the double action of the sabre and the saw, to which there is no parallel in existing races. There were also the pachydermes, and elephants of form more stupendous than these of Siam of the present day, as might be easily ascertained by comparing the bone lying at Chuny's foot in the museum of the College, with the corresponding bones in the skeleton of the animal itself. Within the last two or three years from two to three thousand specimens of the remains of British mammoths have passed through the professor's hands. Of the rhinoceros, also two or three species have been discovered in England, which are now extinct. they were far more formidable than those now in existence. In the older strata of the tertiary formation, the miocene and the eocene, the genera which were found are now totally extinct, and corresponded with the strange ano plotheria and palaeotheria restored by Cuvier from remains found in corresponding geological strata near Paris.

Mr Owen then again referred to the spine of the fœtus, which, in its formation of body and arch, is again found in the larger cold blooded animals, such as the crocodile. The body of the vertebra in the adult crocodile is concavo-convex, and forms a ball and socket joint, but it is not so in the fœtus of that animal. Both surfaces of the vertebra are then concave, the convexity being afterwards formed by ossification taking place in part of the inter-vertebral substance, which afterwards becomes ossified to the body of the bone. The same thing takes place in the tadpole and the frog, whilst the syren retains the bi-concave structure. To return to the concavity of the bodies of the vertebræ, the fossil crocodiles of Great Britain generally retain the fœtal concavity, and this is especially the case with the other saurians, such as the ichthyosaurus, etc. Other examples were cited of the longer retention, by primeval extinct forms of organic character which are embryonic and transitional in the corresponding existing species.

One of the most unexpected and extraordinary applications of these facts is to geographical science. On finding remains of the mammoth, elephant, etc, in this country, exactly as they are found on the continent, we are led to conclude that England originally formed a part of the continent, to admit of their migration thence. When the different kinds of mammalia in one country are compared with those existing in other parts of the world, a peculiar geographical distribution of such becomes evident. Each particular portion of land has certain families of animals particularly located on it. Buffon has stated, with regard to existing species, that all the genera of mammalia found in South America were peculiar to that continent. The only exception to this appears to be the tapir of South America, which was found by Sir Stamford Raffles in one of the islands of the Indian Archipelago. In Australia, the class of animals are very extraordinary. Almost all the quadrupeds there are provided with a marsupial pouch, although not belonging to the opossum genus of America. It is quite a marsupial population. In the islands of New Zealand, when they were discovered by Capt Cook, there does not appear to have been any indigenous quadruped except a small rat, which, in all probability, had been introduced by man. The highest organized animals of New Zealand, next below them, were birds and the largest and most peculiar representative of the New Zealand forms of that class was a wingless bird, the apteryx, about the size of a pheasant.

The fossil animals of England, found in the diluvium and pliocene strata, are the same, generally as those now found in the living state in Europe, Asia, and Africa, we do not find in this country the gigantic armadilloes which are discovered in the corresponding strata of America. The same rule obtains in Australia, where are discovered in the newer strata of the tertiary formation, gigantic kangaroos and other large extinct marsupial animals. In New Zealand there are found the remains of the struthious tribes of a genus (Dinornis) nearly allied to the apteryx and of which from eight to nine distinct species have been found. Several of these extinct birds have been discovered, one towering to the height of ten feet, and their remains brought home by the exertions of Mr Earl, a most zealous and indefatigable naturalist of New Zealand, now present.

Mr Owen then, after making some general remarks on the great importance and various applications of anatomy, as instanced by the observations just made, proceeded to illustrate and explain Cuvier's classification of the animal kingdom. The Linnæan and Aristotelian classifications were first commented on, and shown to be incapable of general application, after which the arrangement of Cuvier founded on the nervous structure, was demonstrated by special examples.

The following is the classification adopted by that great naturalist:—

Primary Divisions and Classes of the Animal Kingdom

Vertebrata and Myelencephala

Mammalia—aves reptilia pisces

Mollusca, or		Articulata, or
Heterogangliata,		Homogangliata,
Cephalopoda,		Crustacea,
Pteropoda,		Arachnodes,
Lamellibranchiata,		Insecta,
Palliobranchiata,		Annulata,
Tunicata,		Cirripedia
	Zoophyta	
Nematoneura,		Acuta
	Radiaria.	
Echinoderma,		Acalephæ
	Polypi	
Cilliobrachiata,		Nudibrachiata
	Entozoa	
Cœlelmintha,		Sterelmintha.
	Infusoria	
Rotifera,		Polygastrica

In concluding his lecture, Mr Owen observed, that in the course of these lectures, which would extend over two years, he would give a general summary of comparative anatomy, so as to enable those students who attended, to obtain a general elementary knowledge of the whole sphere of comparative anatomy.

We understand that Mr Langbridge, the well-known bookseller of Birmingham, has added to his business that of Mr Lyon (late Mr Barlow), the *medical* publisher. We felicitate our Birmingham brethren on the fact that the interests of their medical literature will be thus placed in good keeping.

CASE OF NATURAL SOMNAMBULISM AND CATALEPSY, TREATED BY HYPNOTISM;

WITH REMARKS ON THE PHENOMENA PRESENTED DURING THE SPONTANEOUS SOMNAMBULISM, AS WELL AS THAT INDUCED BY VARIOUS ARTIFICIAL PROCESSES.

By JAMES BRAID, (of Manchester), M.R.C.S.E.

IN No 286, vol. xi of the *Medical Times*, I brought up the history of Martha Scott's case, under the above heading, to the 16th October, 1844. She had, as your readers may remember, been subject to two or more attacks of spontaneous somnambulism daily for some time prior to my attendance on the 2nd of August, 1844, when the hypnotic treatment was commenced, whereas, after commencing this treatment, she had only *one* attack on each of the two following days, none the next two days, one the next day, and *none for nine days thereafter*. Moreover, in sixteen days after she was subjected to the hypnotic treatment the *menses appeared for the first time*. At this crisis she had four attacks within three days, remained entirely free for the next five days, when she had one, and one also on the 26th, 28th, and 30th of August, after which she remained entirely free from them for a week. It is important to remark, that from the 16th to the 30th of August, during which she had these eight spontaneous attacks, I had only had the opportunity of hypnotising her once, which was on the 26th. She was again hypnotised on the 30th and had no recurrence of the spontaneous attacks till the 7th of September, when the menses appeared for the *second time*. She had one slight attack at the expiration of another week, from which she was aroused with the greatest facility. From the end of August to the 1st of October I had only the opportunity of hypnotising her twice and during that period she had eight spontaneous attacks, the latter of which occurred on the 30th of September, and rendered her speechless for eighteen hours. By hypnotising her, speech was speedily restored, and in three hours thereafter the menstrual discharge appeared for the *third* time. She was hypnotised the three following days, when she again ceased attending me, but, on calling at her father's house twelve days after, I found that she had remained quite well and free from the attacks for the preceding sixteen days. Moreover, I had prescribed no medicine, but trusted entirely to the counter stimulus of hypnotism to arrest the tendency to the spontaneous attacks of somnambulism,—so that any change induced was, of course attributable to hypnotism only. As it may be interesting to many of your readers to hear the ultimate result of the case, I now forward you a report of it up to this date, when I consider she may be fairly pronounced cured, being in excellent health, and having had no attack of the sort for five months and a half.

On the 18th of October 1844, she had a spontaneous attack of somnambulism. In consequence of this she resumed the hypnotic treatment on the 21st, 22nd and 24th of that month, and on the latter day she had a spontaneous attack, was hypnotised on the 25th, 26th, and 27th, and on the latter day the menstrual discharge took place. She was hypnotised daily for the next six days. On the 3rd, 4th, and 5th of November she had an attack of spontaneous somnambulism daily, the latter of which lasted for five hours. I beg to call attention to the fact that these attacks took place *at the cessation of the menstrual discharge*.

November 6th I visited her at home. She complained of intense head ache, was much flushed, bowels much confined, and no stool that day. Hypnotised her as usual, and, during the sleep, the idea occurred to me to try whether it might not be possible to excite the function of the bowels through calling the *attention* to their function, by giving her a mouthful of water to drink, predicating aloud, in her hearing, that what I had given her would cause the bowels to move in five minutes. I had never tried such an experiment before, but knowing what the mesmerists had recorded as to the efficacy of *mesmerised water*, I was inclined to believe that what they took to be the results of their passes over the water or bottle

containing it, might be from no specific influence thereby imparted to it, but entirely due to the power of a vivid mental impression, or belief, concentrating the nervous energy, and thus changing or exciting the physical action of the organ or part to which the attention was thus directed. With this view I desired the mother to bring me a little water in a cup, of which I gave her about a table-spoonful, *predicating aloud in the patient's hearing* that what I had given her *would move her bowels in five minutes.* I was careful to arouse her at the expiration of the period named, with this impression vividly on her mind, which was accomplished by repeating the predication after the patient had been *partially aroused. She immediately repaired ad cloacinum*, and shortly returned with the report *that she had had a plentiful evacuation.* In an affair of this sort I did not wish to rest satisfied simply with her report. Although I never had occasion to suspect her integrity, still it appeared to me that it would be more satisfactory to have ocular demonstration of the fact by examining the stool. Circumstances, however, rendered this all but impossible. I, therefore, determined to try the result of a repetition of the experiment, immediately hypnotized her again, and gave her another dose of plain water, accompanied with the like prediction. In the mean time I requested her mother to place an empty vessel in her chamber, as I wished to examine the character of the evacuation. On being aroused, as before, at the expiration of the stipulated period, she repaired to her chamber, and thus, before I left the house I had ocular demonstration of the efficacy of my experiment, as she had had another stool, very costive. Moreover, she had three loose stools after this in the course of the same afternoon and evening, and three or four more the following day, with complete relief of the head-ache, flushing of the face, or tendency to the spontaneous attacks of somnambulism. The last attack of the sort which she has had was on the 7th of November, so that she has now been entirely free from them for *more than five months and a half*, and her bowels have not required aperient medicine during that period.*

She was hypnotised on the 7th, 8th, 9th, 10th, 11th, 12th, and 30th of November. She again menstruated on the 21st of November.

25th Dec.—I called to inquire for my patient, and ascertained from the mother that she had been quite well from the period when I last saw her, and that she had menstruated on the 17th. I have seen her occasionally since; called the last time on the 22nd of April. She had menstruated three times—one in January, February, and the last time 29th of March; and appears quite well in every respect, having had no recurrence of her fits of spontaneous somnambulism for *five months and a half*, and I beg leave to repeat, that *I have trusted entirely to hypnotism in the treatment of this case, having never prescribed a single dose of medicine to her, either external or internal, throughout the whole treatment of her case.*

As the patient has now been so long free from these attacks, is also in the enjoyment of perfect health, and the female function of menstruation has been fairly established—she has menstruated nine times since being first hypnotised—I presume she may reasonably be pronounced cured.

The case I consider as most valuable and important in many respects. It clearly proves the power of the artificially induced sleep to cure the spontaneous fits of somnambulism, as well as to excite the uterine function, which in this case was evidently intimately connected with them.

The case also afforded an admirable opportunity of testing the phenomena of spontaneous somnambulism, and comparing them with the phenomena manifested during the sleep induced by various mesmeric and hypnotic processes. As already stated, the phenomena manifested were as nearly as possible the same, whether the sleep occurred spontaneously or was induced by artificial contrivance. This was fully admitted by all who witnessed the experiments—mesmerists, hypnotists, and also by those who were attached to no theory whatever in regard to the cause of the phenomena. It was thus clearly proved that an *exoteric influence* was quite unnecessary to enable us to realise various phenomena alleged by the mesmerists as entirely depending upon some such influence—such as attachment to the mesmerizer, &c. &c., as noted in the record of experiments on the 2nd and 3rd of August, to which I beg to refer. I was by this case enabled, amongst other things, to prove that some patients have the use of their eyes during the sleep, seeing through their partially closed eyelids, and have since met with several cases of the sort. In short, this case proved, in the clearest manner, the correctness of all the leading propositions which were advanced in my previous publications, and confirmed as real others which had been merely suggested as probable. Thus it proved the *subjective* or *personal nature of the influence;* the reality of all the primary, leading, and useful phenomena; the peculiar condition of the organs of special sense—their extreme exaltation or depression, according to circumstances; and the peculiar relative condition of the memory, reason, imagination and will. I am perfectly aware that to those who have not had an opportunity of classing such a case as this with others of a similar nature, manifested by individuals known to themselves as persons of the highest moral attributes, and where, of course, all idea of their acting a part to impose upon others was quite out of the question; it might readily be supposed that this patient had been acting on certain occasions recorded with the view of deceiving the spectators. I have no hesitation in saying that had this been the *only* case of the sort which I had had an opportunity of investigating, I might have supposed my patient as merely an example of that extreme cunning and desire for display and trickery so frequently manifested by hysteric patients. However, I have seen analogous phenomena manifested by so many patients, both young and old, male and female subjects, of *the most unimpeachable character*, SOME OF THEM NEAR RELATIVES OF MY OWN, where I am *certain the manifestations admit of a totally different construction from that of acting with the desire to deceive others*, that in all fairness, therefore, I am bound to class this patient along with the others referred to. Instead of acting with the view of deceiving others, I am quite confident that they act under erroneous impressions, and are thus *self deceived:* the extreme vividness of the imagination, the torpor of reason, and the passiveness of volition, leading them, at a certain stage, to invest every idea arising in the mind, whether from external or internal suggestion, with all the attributes of present reality; and their extreme mobility, docility, and sympathy, lead them instantly to act in accordance with the import of such erroneous ideas. This is quite analogous to the phenomena of dreaming, *in so far as ideas are concerned*—the ideas being viewed as realities by the dreamer, because he has no means of correcting his erroneous impressions by an appeal to other senses. It differs, however, from ordinary dreaming in respect to the *physical condition.* In ordinary dreaming there is no *physical activity*, but in this artificial somnambulism, physical manifestations are superadded, as is well known to occur during *natural somnambulism.* I know, as a fact, that through this peculiar condition of the nervous system, patients may be made dupes to suggested ideas, *in opposition to the ordinary laws of sensation;* and, just as we experience during nightmare, imagining ourselves struggling to throw off some heavy load whilst the muscles are perfectly passive, so in like manner, from impressing a patient with the idea of an object being so heavy *that it will be impossible for him to lift it*, he will imagine himself and appear to others as putting out all his energies, *and yet feel himself incapable of lifting a small book*, FROM THE IDEA HAVING PARALYSED HIS ENERGY OR VOLITION,—and yet the moment thereafter, when the idea has been excited in his mind of the extreme LEVITY of the object he is about to lift, it will be lifted with the greatest facility, and pronounced, perhaps, only a few ounces in weight. In short, it is quite easy either to *paralyze or energize volition and muscular power* in such cases through auricular suggestion, imagination, and belief, so as to render the subject *totally powerless*, or to enable him to perform *a feat of strength with ease, of which he is wholly incapable during the waking condition.*†

It is of great consequence that the condition of the memory, reason, imagination, and will, as well as of the perceptive faculties generally, during the different stages of hypnotism, should be correctly understood, for without this knowledge it is impossible for any person to judge correctly between what is true and what is simulated. During the *first conscious state*—that is, during which they can remember on awaking all which happened during the sleep—I consider their actions, generally, are as strictly *voluntary* acts, or at least nearly so, as during the waking condition; but, for the reasons assigned above, I consider that the moment they pass this boundary, and enter into the *second conscious* state, they assume an entirely new phasis. However, I shall not encroach further on your valuable space by enlarging on these topics at present, as I intend shortly to do so in the form of a sequel to my little work on hypnotism, to be entitled "ISIS INTERROGATA," which shall also have a chapter devoted to the consideration of the extent to which mesmerism and hypnotism may be made available in mitigating or entirely preventing the pain of important surgical operations. I shall also give a full explanation of my theory of the phenomena included in what has been called phreno-mesmerism—namely, automatic muscular action excited through the reflex function of the nerves—suggesting ideas in the mind with which they are usually associated during the waking condition.

It is with no small degree of satisfaction that I am enabled to appeal to a very able article in the *British and Foreign Medical Review* (also published in a separate form), which fully admits as real all the important phenomena which I have contended for—and on similar grounds too—as well as the *subjective or personal nature of the influence.* I consider that article does great credit to the author, as well as to Dr. Forbes, who has appended an admirable prefatory advertisement to it in its separate form. It cannot fail to incline many of the "unreasoning, unenquiring, dogmatic sceptics," to consider before they again so authoritatively denounce, as they have hitherto done, without investigation, what has had such a calm and candid consideration by such parties as Dr. Forbes and the able writer of the said article. Of course

---

* I published an account of the above result of exciting the action of the bowels through mental impression, in the *Medical Times* for January last. These numbers also detailed the result of other three cases where the same experiments were tried with equal success. In one of these cases my operations were followed by an evacuation twenty-eight times in succession before I left the house, (with the exception of once for reasons stated) and I have no doubt but I might have repeated these experiments any number of times with this patient with like success, only I considered it unnecessary after the patient got well. I have since tried the same experiment with equal success in another case, where the patient had been so obstinately costive as not to have more than one stool in six or seven days, but after being twice hypnotised with the like predication, on the latter occasion, the bowels had moved once or twice daily without the aid of medicine. When I last heard of her, it was about six weeks after she was last hypnotised.

† In conversing lately with a scientific friend on this subject, he furnished me with the following interesting anecdote in corroboration of the correctness of these views, which he was able to vouch for as a positive fact. A farm servant subject to rising in his sleep and doing various acts, as recorded of other somnambulists, slept in a room where there was a moveable malt mill, so heavy that it was quite impossible for one person to lift it under ordinary circumstances. One night he arose during his sleep and had *lifted the mill and placed it upon his own bed*, when he awoke and found himself quite unable to remove it from the place where he had placed it during his sleep. He was obliged to awake his fellow-servants to help him to remove it, in order that he might again be enabled to get into bed.

their scepticism in regard to the correctness of the ultra views of the mesmerists, regarding the higher phenomena, will not satisfy those gentlemen any more than the middle neutral ground which I have taken, and the narrow limits within which a careful observation of an immense number of experiments has convinced me I ought to circumscribe the powers and pretensions of *hypnotism*. However, I have not hesitated to avow my convictions candidly and fully, and leave it to time, which brings all things right, to determine whether I am not at least somewhat *nearer* the truth than either the *ultra* mesmerists, who contend for *so much*, or the unenquiring, dogmatic sceptics who will believe *nothing*, and even venture to pronounce authoritatively in regard to matters of observation and fact, before they have taken pains to be correctly informed on the subject.

OBSERVATIONS ON VARIOUS DEBATABLE QUESTIONS ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.

By Dr. Clay, Piccadilly, Manchester.

No. III. Second Series.

(Written expressly for the "Medical Times.")

Subjects :—*Lingering Labour—Vaginal Examinations Pernicious—Admissible in some particular Cases—Case—The Laws of Uterine Action in After Pains Explained—Application to Cases of Internal Hæmorrhage—Application in Hour Glass Contractions.*

I stated at the conclusion of my second article, that there were other circumstances known to accoucheurs as fully illustrative of the subject as those already brought forward in the past observations, for instance, in what is termed lingering labour, the character of the pains (from some cause, as exhaustion, or having been prematurely excited or both) are ineffective, but still the order of the pains is strictly natural, that is, the transverse action precedes, and would, if sufficiently effective, dilate the os uteri; in such a case, and under such circumstances, frequent examinations *per vaginam* are most pernicious, and cannot be too summarily condemned, and why? because they have a direct tendency to provoke the secondary character of pains; in other words, to bring on bearing down, or expulsive efforts, before the os uteri is sufficiently prepared by dilatation. A very slight reflection will explain the cause of these secondary efforts coming on; it is the presence of the accoucheur's fingers stimulating the nervous tissue of the pelvic viscera, and thereby exciting the longitudinal fibres of the uterus, in the same manner as the fæcal matter produced them in the case recited in my second article. But, although frequent examinations are, as a practice, extremely bad, I am prepared to prove (in advocating my views of uterine action) that there are cases directly the opposite to the supposed one just stated, where a judicious manipulation of the accoucheur is effective of *the best results*; they are, however, cases requiring *no little discrimination*. The following case will perhaps explain my meaning more fully than the most elaborate description without it.

Mrs. ——, of Jersey-street, Manchester, was in labour of her fourth child; during the night she had had some hours pain but not very violent; towards morning the pains altogether subsided, and left her in a state of extreme exhaustion; I was called to her about ten o'clock A.M.; I found her very low, but no pains, nor had there been any since between five and six o'clock that morning (a period of more than four hours). On examination, however, I found the os uteri fully dilated, the membranes perfect and flaccid, with a perfectly natural presentation to all appearance; if pains had been present, I should have calculated on a completion of the process in a few minutes. This case was one in which the secale cornutum promised to be an efficient help, and whilst the infusion was preparing, it occurred to me to try the effect of pressure on the inner sacral curve with the fingers, with the view of exciting the longitudinal fibres to expulsive pains; I therefore introduced gradually three fingers into the vagina, and with the inner flat surface of the three fingers joined, I made a gentle but steady pressure downwards (as though it was the child's head on the perinæum). Immediately on so doing, a slight expulsive effort was manifest. After an interval of a couple of minutes, I repeated the pressure, when another and stronger expulsive effort occurred. From the downward pressure of the presentation at the second trial, I felt convinced the labour would soon terminate. By the time I had repeated the pressure the fifth time, the pains and expulsive efforts were strong, and did not require any further excitement; the labour was completed easily within three quarters of an hour from the first trial of the artificial pressure, without the assistance of the secale cornutum, and when there was not the slightest prospect of the pains being resumed. This case is instructive, as it serves to show, that after the transverse contractions of the uterus had fully accomplished the necessary dilatation, there existed a decided want of action in the longitudinal fibres, which probably arose from the exhaustion present, but when the nervous tissue of the pelvic viscera was excited by artificial pressure (as was the case with the fæcal matter in a former case), the longitudinal fibres became active, and a rapid completion of the delivery was the result. Thus, then, when sufficient dilatation has occurred, when the longitudinal action is deficient or wanting, artificial pressure, which in most other cases would be deemed pernicious, would in this case be justifiable. These peculiar differences of uterine action are also observable in what are termed after pains. It is well known that after pains are of the expulsive character, and they are necessary to keep the cavity of the uterus clear from such collections of matter as necessarily arise, to reduce the size of the uterus, and whilst the metastasis of milk forming takes place. After first labours there are very few, and, in many cases, no after pains; this arises from the generally more vigorous constitutions, in which the uterus more immediately and rapidly contracts to its original unimpregnated size, affording less room for collection of material, and therefore less occasion for expulsive efforts to eject it. I have generally observed as a natural consequence, that the milk in these cases is secreted more in proportion, and more rapidly, where the after pains are few, and the after discharge trifling; on the contrary, where the discharge is excessive, and the uterus a long time before it assumes its normal size, the milk is longer in being secreted. It must be recollected, that when the situation of the uterus is considered after labour, together with its size, that it has become pelvic, and not abdominal, as *before labour*, and therefore the pelvic pressure of the mass, increased by the lochia, excites the expulsive longitudinal fibres, whilst the transverse, having lost all their tensity, are quiescent. Thus, the same law of uterine action is observable after the child is born as before, and from the same exciting causes. I recollect some years ago being sent for by a medical friend to assist him in a case of internal hæmorrhage—the uterus was filled to a large extent by coagula; the longitudinal fibres were perfectly quiescent, consequently there were no efforts of expulsion, but I observed clearly there were slight transverse pains, which, in consequence of the exhaustion from loss of blood, were very slight, nevertheless they were present, and certainly were efforts of nature which, under proper circumstances, and sufficient physical powers, would have eventually brought on expulsive efforts, but, with the loss of blood, this was of course hopeless. This transverse action arose from the tensity of the fibres, by the uterus being filled with coagula; and I also observed, when the hand was introduced to clear out the coagula, slight bearing down efforts were manifested, in consequence of the pelvic visceral excitement by the presence of the hand, only wanting in effect from the state of exhaustion; indeed, the ultimate introduction of the hand within the uterus, is equally as much for exciting the longitudinal fibres, as to clear out the coagula, else the clearing out of the coagula would be of little use, as the cavity would be soon filled again. There is yet another view to be taken of this subject, and that is in reference to what is usually, but very incorrectly called hour glass contractions; if it is to be understood by hour glass contraction, that there is a perfect analogy in form to the hour glass when under the influence of this action, nothing can be more erroneous and absurd; without doubt, there are irregular contractions of the uterus, something analagous to the hour glass, inasmuch as the os and cervix uteri are in a relaxed state, whilst it is presumed the fundus uteri is also in the same state with the placenta enclosed, and that between these there exists a strong contraction of the transverse fibres. Dr. Campbell of Edinburgh, in his system of midwifery, denies hour glass contraction altogether, but this seems to be a mere war of words; he surely cannot deny that irregular contractions of transverse fibres sometimes take place, whilst the longitudinal fibres of the fundus and cervix uteri are in a state of inaction, and though the form may not be strictly that of the hour glass, yet it is something analogous, and might have a worse name, though I think it would be more correct to call it irregular contraction. There are few practitioners that have not had an opportunity of witnessing cases of this description, but all their evidence goes to show, that the contraction is not in the centre of the uterine structure, and on a very slight reflection it will, I think, be admitted, that a central contraction would be impossible, for we have only to call to mind the immense reduction in size of the uterus after the child is expelled; then, with this reduction in size we have a large body, as the placenta, occupying the fundus, with the contraction beneath, leaving but little of the os and cervix uteri below to be in a relaxed state, so that instead of its figure being as No. 1. it would be that of No. 2.

No. 1.

No. 2.

After all, this is the same in principle, differing only in shape; I shall in my next article, shew the application of the foregoing views of uterine action, in connection with this irregular action.

(To be continued.)

ON VACCINATION.

By Robert Lewins, M.D.

Fellow of the Edinburgh Royal College of Physicians, &c.

In the following extract from my work on vaccination, published in 1825, we have, I conceive, a satisfactory response to the queries appended to Mr. Blackall's interesting case of modified variola, after, or rather, concomitantly with, small-pox, recorded in the Medical Times of May 3d. The extract is the more worthy a place in your pages, that the information it communicates is practically important.

"There is great reason to suppose that by far the most frequent cause of the apparent failure of vaccination has arisen from the operation being performed at an improper time, when the system was capable of resisting the legitimate action of cow-pock matter. We are not, yet, acquainted with all the causes that may affect the human body in this manner; but there is reason to suppose that the existence of some other disease at the time will produce this effect; and we know, for certain, that cutaneous diseases especially do so. If the skin, over the whole body of the subject vaccinated, be not quite sound, the pustules do not go through their course with their wonted regularity; nor is absolute protection afforded against a future attack of small-pox. The indefatigable Jenner was aware of this at an early stage of his inquiry, and said—'If I were asked what were the other actual impediments to perfect vaccination, as a general answer, I should say that I scarcely know any other, except spurious matter, or impediments too obvious to require my naming them here, such as deranging the vaccine vesicle

in its progress, by incautiously robbing it of its contents, or producing a new action by external violence.

In the concluding part of Dr. Jenner's letter which I have quoted, we have an example of the candour and caution which characterised the mind of that illustrious man. In explaining the causes of apparent failure of vaccination, he confined himself strictly to that which he knew was matter of fact. Subsequent experience has made us acquainted with other causes of failure.

The existence of any other disease at the time vaccination is practised will modify its action, or render it entirely nugatory. Fever, dentition, inflammatory affections of the lungs, and diarrhœa, co-existent, are, I believe, the most common causes of the failure of vaccination. As the strongest and most convincing proof of the accuracy of Dr. Jenner's sentiments, as well as of Dr. George Gregory's and my own, with regard to the counteracting and controlling power of general and local disease, under the circumstances to which we have just been alluding, I shall here narrate the history of a case that came under my observation:—

About two years ago, when small-pox were prevalent at Haddington, amongst the unvaccinated, they attacked a family in the suburbs, where there were several unvaccinated children. I heard nothing of this family until all the children, not protected by the ægis of Jenner, were covered with small-pox, except an infant about three months old, which was instantly vaccinated. Three days after the cow-pock matter had been inserted, small-pox made their appearance upon the body of the child, but the pustules were scanty in number, soon maturated, healed kindly and expeditiously. The primary fever was mild, and there was no secondary fever; and whilst we thus observed, with surprise and satisfaction, the effect and controlling power of vaccination, performed under these unfavourable circumstances, we also witnessed the cow-pox on the arm of the vaccinated, in its turn, modified by the presence of the small-pox. The former had, in what I should consider a perfect degree, the appearance which they assume when herpetic eruptions, or ulceration, exist upon the body of a patient at the period of vaccination; and I may mention, as a still more extraordinary illustration of the wonderful power of vaccination practised under the most unfavourable circumstances it is possible to conceive, that Mr. Kesson, of North Berwick, some time ago vaccinated a baby the moment it was born, in a small, filthy, ill-ventilated apartment, where small-pox were raging in all their horrors at the time, and when the bodies of two children who had died the same night, were actually lying in an adjacent bed. The infant was affected with both diseases; but so completely did the vaccine modify and subdue the variolous, that there were not above thirty or forty pustules; and the subsequent history of the little sufferer was so similar to the one mentioned above, that a further account of it is here unnecessary.

What I have just mentioned with regard to the effects of the cow-pox on small-pox, and *vice versa*, was observed on a large scale in the small-pox hospitals in London, and, I believe, other parts of England, soon after the introduction of vaccination. The patients were received into the infected wards, and there vaccinated. Before the cow-pock matter had time to produce its specific effect, many of them were influenced by the small-pox infection, and both diseases went on at the same time, but invariably in a mild form, so that the nature of the disease became a matter of dispute between the illustrious discoverer of the blessings of vaccination, and the very intelligent Dr. Woodville. That it was real small-pox, modified and subdued by vaccination, soon became evident. Mr. Paytherus, of Norfolk-street, London, showed this as early as 1801."

The East India Company have appointed Mr. Edward Solly Lecturer on Chemistry at the Military Academy at Addiscombe, vacant by the death of Professor Daniell.

PROGRESS OF FRENCH SCIENCE.

FROM OUR OWN CORRESPONDENT.

Paris, May 1, 1845.

On Accidental Retraction of the Limbs. By Dr. Morel Lavallée. *Pathology* (continued) (*c*).—*Accidental fibrous tissue.* The only cicatrices capable of causing retraction of the limbs are those which follow a loss of substance of the skin and subjacent tissues. There are two varieties: in the one, the lips of the wound brought in immediate contact in the first instance, are separated only by a thin layer of inodular tissue, which itself very frequently disappears; the parts are, in this case, simply shortened in a direct ratio with the loss of substance. In the second, and it is this which will principally occupy our attention, the loss of substance is replaced by a new membrane, somewhat smaller than the space it is destined to fill, whose mobility is imperfect, and whose elasticity is null. The mechanism by which retraction takes place in this case, is composed of three elements, two acting constantly, the third only occasionally. Let us examine these cicatrices with respect to their mode of formation, their texture, and their properties. *Mode of formation.*—This may be explained in a few words, because it has no relation with the subject under consideration, and because whatever may be admitted will be mentioned under the second head. Of all the solutions of continuity with loss of substance, wounds alone are capable of having their lips brought in immediate contact; in these cases, the hæmorrhage is followed by turgidity, serous effusion and secretion of plastic lymph, which becoming organised, as will presently be shown, unites the cut surfaces. This is what is called *immediate union* without suppuration; the inflammation which produces it, is simply adhesive, and does not reach a degree sufficiently intense to constitute a phlegmasia (Delpech). Cicatrisation takes place in an internal wound, because the perfect union of the lips of the divided parts, places them in the same position, that is to say, contiguity of the living tissues with each other, without their being subjected to the irritating influence of atmospheric air, or any other foreign body, except on the line formed by the union of the lips of the wound. The result is very different when the sides of the solution of continuity remain separated, for then it is subjected to the action of the atmosphere, and other causes, which exercise a very unfavourable influence, and give rise to *suppurative* inflammation. Whilst the sero-sanguinolent discharge continues, the cellular tissue reddens, is covered with granulations, and furnishes first pus, and afterwards—doubtlessly when prepared to perform its destined restorative part—it secretes plastic lymph, organizable matter. This last is the same as that in which the primordial cellular tissue is formed, and which Schwann denominated *cytoblastema*, a liquid containing a dry grey-powder, which Guiterbrock, who discovered it in pus, called pyine. This powder is to be met with in the skin of the embryo, in the membrane covering the granulations of ulcers, in short, wherever the cellular tissue is imperfectly developed.

It is by means of this exudation that the cicatrix is formed, and according to Schwann the changes the parts undergo are as follows:—Cells with nuclei first appear; each nucleus contains from two to four granular bodies, which may be isolated by means of maceration or acetic acid; the cells and nuclei are changed into different kinds of fibres; thus there are fibres corresponding to the cells, and fibres corresponding to the nuclei. This opinion adopted by almost all the German micographers, is notwithstanding thought by some to be erroneous. As to the origin and development of the vascular system, opinions differ; thus Henle, who discovered several varieties of cellular fibres, and the minute granular amorphous substance which separates them, considers as vessels, what Schwann supposes to be nothing more than radiated cells, emanating from the metamorphoses of the cells. Some writers assert that the vessels commence in the cells themselves, others in the intercellular spaces; these differences of opinion, added to the great difficulties attendant on these researches, naturally inspires but little confidence as to the mode by which this organisation takes place; be that as it may, it presents phenomena, which are easily certified, and of the highest interest. According as the edges of the wound diminish, the plastic lymph covering its surface is deposited in concentric zones, proceeding from the circumference to the centre, or in small spots, which communicate with each other by means of narrow bands, the intervals left between them gradually healing. The highly vascular cicatrix diminishes by degrees in extent, and is covered by an epidermis; its colour at first is of a roseate hue, and afterwards of a dull white; the red or bluish tint is a sign of congestion or weakness, which portends a renewal of the ulcers; no hair, nor follicles, nor sudoriferous ducts, nor pigments, except, perhaps, in some negroes after a considerable time has elapsed; the internal surface is different from that of the dermis by the absence of the fatty areolæ. Anatomy has ascertained with difficulty the presence of vessels, and no nerves have as yet been discovered, though physiology indicates their existence. As to the nature of this accidental tissue, it is evidently fibrous; its fibres are of a dull white, without the least red or yellow tinge, and do not resemble in any respect those of the mammifere or birds; it does not present the lustre of aponeurosis, nor the satin-like appearance of tendons, but it possesses a density equal to that of these two tissues, though its fibres are not so regularly disposed, nor so closely united to each other; they are not similar either in colour or elasticity to the intervertebral ligaments, and still less to the elastic ligaments in the wings of large birds. It is firmer than the fibrous tissue of the middle membrane of the arteries, for it is distended with considerable difficulty, and it cannot be crushed by perpendicular pressure whilst that of the artery is easily divided by a ligature. In its aspect this new tissue resembles somewhat the muscles of certain reptiles, such as frogs; for consistency and density it may be compared to the strongest articular ligament. Its fibres are not very extensile, and retract as soon as the force which elongates them ceases to act. It is, likewise, endowed with a contractile, or rather retractile power, independent of volition, which acts slowly, though constantly, may be increased by inflammation, and which can be overcome only by an equally powerful mechanical force. (1)

It is precisely this retractility manifested long after the apparent termination of the production of this tissue, which explains the peculiar property it possesses in causing the various deformities. If it persists after the formation of the cicatrix, it likewise commences with it, for as soon as the inodular tissue appears, it powerfully draws the edges of the wound inwards. This is in proportion to the size of the suppurating surface; if a cicatrix of a given diameter retracts as 1; another twice as large will retract as 2, to the mobility of the surrounding tissue; at the nape of the neck, where the integuments are firmly fixed to the subjacent parts, they resist the concentric efforts of the cicatrix, which consequently will be almost of the size of the primitive dimensions of the the wound. It also differs according to the part of limb on which it is situated; thus on the sides of the joints, for instance the ginglymi where no movement exists, even if the mobility of the skin permitted the retraction, the limb would retain its normal direction, but this is not the case when the lesion is situated on their anterior or posterior surface; the deformity then may be extreme, and flexion or extension may be more or less diminished and even abolished; the fingers may be drawn into the palm of the hand; the hand on the fore-arm; the fore-arm on the arm; the toes pulled upwards; the feet deviated in various directions; the leg drawn backwards, and the thigh forwards: these are the species of retractions generally produced by cicatrices. Though the lesion is usually greater after a burn, yet it is doubtful whether it could be carried to a greater extent than in the following case. An old atonic ulcer situated on the instep healed slowly; a thick band

(1) Delpech. Chirurgie Clinique de Montpellier, vol. ii. p. 377.

extended almost perpendicularly from the anterior part of the leg to the foot; the first row of the bones of the tarsus were dislocated, so that the direction of the foot remained horizontal, and seemed as if it had been made to ascend on the anterior surface of the tibia, owing to the retraction of the tissues. This curious case was successfully treated by a surgeon of Nantes, and a model may be seen in Dr. Bouvier's collection.

3° *Pathology of the Tissues which are not the seat of Retraction* (*a*) *Muscles.*—With the loss of mobility, life seems to have abandoned the part, since the antagonists of the retracted muscles are not only elongated, but they also become thinner and paler, and undergo the same lesions as their opponents—lesions which generally terminate in the fatty degenerescence. In retraction produced by fibrous tissues, it is only at a very advanced stage of the disorder, that the muscles condemned to inactivity become the seat of these lesions (*b*) *Albuginous tissues.* Their lesions are sometimes hardly perceptible, the size of the tendon remaining normal; it may, however, augment in volume, and even becomes thicker than the muscle, as in some cases of club-foot, where the leg appears reversed, and is larger inferiorly. According to M. Bonnet, the elongated ligaments are hypertrophied as well as those that are shortened, but, as has already been explained, there is an evident contradiction in this statement—(*c*) *vessels and nerves.* The lesions presented by the veins are very slight; as to the arteries, their calibre alone is diminished, their length remaining the same; this latter peculiarity is the cause of various changes of position, a fact which did not escape the observation of MM. Scoutteten, Bonnet, and some others. It should never be forgotten. But though this frequently occurs, still it is not constant; in fact, in a case of ankylosis of the knee, ere the limb was straitened by the apparatus invented by M. Louvrier, the popliteal artery was torn, proving that it had followed the general rule and retracted, for no part of the apparatus had touched it. Nerves diminish in length, so as to accommodate themselves to the space they are destined to fill; their direction and their size are unchanged. (*d*)—*Bones.* After the organs which are ordinarily the seat of retraction, the bones are the most frequently affected. Their position and their shape are modified, because the traction they experience causes them to deviate from their normal direction, and to be subjected to pressure in parts which, in the normal condition, are free from it. Are short bones acted upon? They are flattened on the side of the joint on which pressure takes place, whilst they increase in size on the opposite side, and tend to escape like a wedge on whose summit pressure is made. It is in this way that the semi- or complete dislocations of certain bones of the tarsus are produced in some cases of club-foot; as the normal articulations are destroyed, false ones are established. In the places in which, owing to these changes of position, the cartilages and synovial membranes are laid bare, they are absorbed, and new ones are formed where the bones are in contact. This deformity is sometimes carried to such an extent as to render it impossible to recognise the bone, and in these cases, by the union of partial deformities, considerable deviation may be produced even when no luxation exists. It is thus that a lesion, simple at its commencement, and formed merely by the retraction of a few muscles, becomes a serious affair. As to the long bones, they are seldom so deeply affected, but are generally only drawn in the direction of the retracted tissues.—These lesions are described as they exist in their last stage in order to render them more easily understood; it must, however, not be forgotten that they often cease to increase at a very early period, in direct muscular retraction caused by a disturbance of the nervous system, and remain stationary or increase but slightly. In other cases, the change may be very slight or even null, as in the hand, and in retractions which have lasted but a very short time.

III.—*Symptoms.*—Retractions of the *muscles and normal albugineous tissue* commence in an acute or chronic form. In the former, the origin is a convulsive disease of the nervous centres, and in both, a violent direct or indirect action on the organs themselves; such as wounds, inflammation, and irritation, propagated from the neighbouring parts. The development of the retraction is rapid, and its symptoms are mingled with those—more or less numerous—of the disease by which it is produced. Thus, in suppurating wounds of the limbs, there is at the same time swelling, &c. of the surrounding parts. But these complications disappear with the exciting cause, and then the retraction presents its pathognomonic characters. When owing to a faulty position, to moderate pressure, or causes not more energetic, it is established slowly, it presents its pathognomonic signs at the very outset. The only differences presented by these symptoms are relative to their intensity. They may be comprised under two heads: 1° *Local symptoms.* Pain does not exist when the retraction has existed some time, whether it remains stationary or augments; the only exception is the syphilitic retraction, which, like osteocopi, is accompanied with intense pain, increasing at night. Rigidity, firmness by which the situation and the shape of the diseased part is rendered more distinct: thus in the palm of the hand, the flexor tendons or aponeurotic bands raise the skin like so many tightened cords. This is not so visible in other parts of the body, and when the retraction takes place in the direction of extension, it does not appear unless the bones are considerably out of place. Nay more, that which is natural to the tendo Achillis, causes it to disappear in a direct ratio with the shortening, for as it increases it raises the os calcis, and causes the lower insertion of the tendon to approach the tibia. As to the subcutaneous bands, they may be felt and sometimes seen—symptoms as variable as their mode of development. The membranes or deep seated bands are not only invisible externally, but likewise are felt with considerable difficulty through the parts which cover them. The word *retraction* seems to imply the presence of an angle, which in fact exists in the majority of cases, whether the disease is situated on the sides of the joint, or in the direction in which flexion takes place. This angle may likewise be produced in a contrary direction; *i. e.* extension, when the affection is carried to such an extent, as to bend the limb in a direction opposite to the normal state. But, instead of attaining this limit, retraction generally ceases to develop itself when it has fixed the limb in a straight line. This variety is evidently of the same species as the preceding, and if it manifests itself in a different manner, it is owing to secondary causes which are too clear to need to be indicated.—The retracted tissue draws the moveable part to which it is attached, either directly or by means of another organ, in the direction of one of the normal movements of the limb, limiting at the same time the opposite one. Considerable variety may here be observed; thus flexion may be hardly perceptible, or proceed until the parts are physically prevented from going further by an obstacle which they cannot overcome—from a slight flexion of the fingers, to the penetration of the nails in the ulcerated skin of the palm of the hand (Velpeau)—from the simple depression of the top of the toes to that in which they are so drawn towards the sole of the foot that the patient walks on the upper surface of that part—from the semi-flexion of the knee to the contact of the heel with the buttocks; the intermediate varieties form however the general rule. In the direction of extension, and on the sides, with the exception of the instep, these lesions are developed to a very slight degree. Types of complicated retractions may be seen in some cases of club-foot, where the part touches the ground by one of its sides and by its tip, and in the superposition of a toe on a neighbouring one. There is, perhaps, another species of complicated retraction, viz. the simultaneous retraction of antagonist muscles. May not the following be considered as an example in the toes? "The first and second phalanges were raised in an acute angle; the patient walked on the sides of the toes, which were enlarged and elongated." (2) A. Cooper, and Boyer describe with more or less precision, the same lesion. Dupuytren attributes the deformity exclusively to the retraction of the aponeurosis: Cooper to that of the flexor and its sheath: Boyer to that of the extensor. But though it may be produced by the three, still in the case related by Dupuytren it was owing to the simultaneous retraction of the flexor and extensor. The distinction in the following case, observed in the wards of Dr. Jobert de Lamballe at St. Louis, is not so easily established, still it may be considered as of the species described by Boyer. (3)—Leduc, ætat 16, upholsterer, was, two years before his admission, afflicted with ulcers on the instep, owing to the parts having been frozen and violently contused, and their cicatrisation was obtained by his remaining six months confined to his bed, after which he was able to move about without limping in the least. In November 1843, he slipped and sprained his left foot outwards; the pain though sufficiently intense to make him limp, still did not oblige him to lay up. From this time and without any other appreciable cause, with pain in the part corresponding to the situation of the extensor muscles, the four last toes of the right foot were drawn upwards, and at the same time the last phalanx was bent downwards. On the patient's entering the hospital all voluntary motion in these toes was abolished, and that of the foot and leg was very limited; when traction was performed on the extremity of the toes, the tendon of the extensor longus digitorum pedis was felt very tense, those of the tibialis anticus and peronæus anticus did not seem to be so.—21st May, the tendons of extensor longus digitorum pedis, were divided by the sub cutaneous method; the immediate result was, the straightening of the bent toes; voluntary motion was however still impossible.—18th June, the patient performs with great facility flexion and extension, but the movements of the foot on the leg, are still difficult. This is easily accounted for, from the fact of the astragalus being twisted in the peronæo-tibial mortise, and forming internally an eminence easily felt.—Since the permanent flexion of the phalanges ceased as soon as the tendons were divided, it was evident that this lesion was caused by the retraction of the extensors, which by forcibly extending the toes, elongated the tendons of the flexor muscles, and as they did not stretch, the last phalanx was bent downwards to restore it to its normal length. This circumstance, though not mentioned, was doubtlessly noticed by the author of the case. According to Professor Gerdy, the muscles which are accustomed to contract together, in general, retract likewise primitively or consecutively, at the same time. This, in M. Bonnet's opinion, takes place whenever the muscles receive their nerves from the same source. The former opinion is, perhaps, the more correct, still it is not without exception, of which a case of retraction of the biceps alone, which will presently be related, is a proof. There are likewise real deviations, in which the limb is drawn on one side in articulations which have no lateral movements. Finally, deformity of the bones, more or less complete, luxations, emaciation of the limb, carried to such an extent as to render the member almost, if not entirely, useless, are to be met with.—2° *Functional Symptoms:* To be more concise, they may, as Professor Gerdy recommends, be comprised under three heads: (*a*) very slight deformity, extent of movements alone diminished; (*b*) articulation bent more or less, movements considerably diminished; (*c*) deformity carried to the highest pitch, movements abolished. In the commencement, the disease frequently disappears spontaneously; for instance, in the fingers, if the person ceases to perform hard manual labour; in parts after the cessation of the lesion which caused it, such as inflammation, or local irritation (erysipelas or diffused phlegmon), or immobility of a limb on account of disease of the joint, or fracture of one of the bones, &c. The retractions which are consecutive to convulsive movements in hysteria, and other nervous affections, generally yield without its being necessary to have recourse to any remedial measures. These successful terminations may be hastened by su

(2) Dupuytren, *Clinique*, vol. IV. p. 509.

(3) This observation was communicated to the author, by M. Rade Senr., one of Dr. Jobert de Lamballe's *internes.*

appropriate treatment. As to the symptoms of retraction by *accidental fibrous tissue*, being those of a cicatrix, with diminution in the movements, their enumeration would be mere tautology, and is therefore useless.

Obliteration of the Pulmonary Artery:—Case communicated by Dr. Richelot to the *Société Medico pratique of Paris*. M. T., solicitor, ætat. 38; general health good; had been affected with a slight cough for the last twenty years; the chest, carefully examined, presented nothing extraordinary; hæmoptysis from time to time; dyspnœa on walking quickly; after a long journey on the 1st November, 1837, he was seized with violent pain in the epigastrium, which yielded to the application of leeches, and other general remedies. 8th.—Hæmoptysis of pure, red blood, dyspnœa; v nesection was proposed, but refused, and the patient continued his wonted vocations, though advised to refrain; a day or two after, he presented all the symptoms of pleuro-pneumonia on the right side; auscultation and percussion were not performed, from the refusal of the patient. Copious venesection, and the usual remedies were had recourse to with success, nothing remaining but slight dyspnœa; when convalescent, he was all at once attacked with approaching suffocation, and fainted away; having recovered his senses, he indicated the epigastrium as the seat of his suffering. This amelioration did not last long, for the feeling of suffocation returned, about half a pound of blood was drawn with difficulty from the arm; the face became livid; violent tenesmus; agitation, followed by prostration and death. Autopsy, 32 hours after. *Thorax*.—Parietes presented the dark red colour peculiar to asphyxia; pericardium contained about three ounces of a sanguinolent serosity; heart normal, its cavities contained a small quantity of clotted blood; left lung presented adhesions of old date; about two pounds of a reddish serosity in the right pleura; a few fragments of the lung thrown into water floated on the surface; both lungs were of a *blackish-red* colour posteriorly and inferiorly, but no *engouement* nor hepatization. "The principal branches of the pulmonary artery were nearly obliterated by clots of black blood, several of which adhered slightly to the walls of the vessels, were soft in their centre, and surrounded by a portion of a somewhat lighter colour; the blood was perfectly liquid every where else." Cranium and abdomen in the normal state. The author concludes that death was produced by syncope, owing to the cessation of the circulation caused by the *obliteration of the pulmonary artery by clots of blood*.

The following nominations have taken place; as Officers of the Legion of Honour: Professor Adelon, M Caventou and Dr. Lordat, Dean of the Faculty of Medicine, Montpellier. Knights: Drs. Amussat, Fabre, H. Larrey, Matteucci, Ehrmann, Professor of the Faculty of Medicine, Strasburgh; Tanchou, des Planches, Cerise, Vernois, Descuret, Denonvilliers, Dize, Becquerel; Roger (U.), Sonac, Director of the Preparatory School, Lyons; Robert, Fiard, Lemaistre, Florian, Lacauchie, Brulatour, of Bordeaux, Sené, of Dijon, Guepin, of Angers, Gourand, Goez, of Douai, Juriani, of Bastia.

Academy of Sciences; Sitting of the 28th April.—M. Elie de Beaumont in the chair.

Researches on Mercury and some of its Compounds, by M. E. Millon.—When mercury is distilled, after having been shaken with a small quantity of nitric acid, the distillation takes place much more slowly towards the close of the operation, and in collecting separately the mercury which is volatilized at the commencement, and at the close of the process, a considerable difference in the volatile power may be remarked. To decide this question, the author performed the following experiments:—1° six retorts were taken, each, when half-filled, contained about 3½ oz. of mercury; the result on distillation was—the retorts being designated by the letters A and B:—

	Retort			Same length of time.
1st Expt.	A	... quantity distilled at	commencement,	48 5 gr.
"	B	"	close,	47 5 gr.
2nd Expt.	A	"	commencement,	69 0 gr.
"	B	"	close,	63 gr.
3rd Expt.	A	"	commencement,	66· gr.
"	B	"	close,	64· gr.

2°—One hundred pounds of mercury were distilled; the first and last two pounds were collected and re-distilled, the retort A containing the former, the retort B the latter; the result was:—

	Retort.			gram.
1st Expt.	A	... quantity distilled during	the same time,	19·
"	B	"	"	49·
2nd Expt.	A	"	"	15·7
"	B	"	"	41·5

In all probability, this was owing to some difference in the degree of purity, but all the tests employed failed in indicating to what this might be attributed.—3° Other metals were added and the results obtained were:

Exp.	Retort	Mercury		Quantity distilled. grammes
1st	A	3½ʒ	with 1-10000th part of lead..	5
	B	..	without	67
2nd	A	..	with 1-10000th part	2·2
	B	..	without	55
3rd	A	..	with 1-10000th part of zinc..	6·5
	B	..	without	87
4th	A	..	with 1-10000th part	2·5
	B	..	without	37·5
5th	A	..	with 1-10000th part of platina	89·5
	B	..	without	70

To obtain this last result the platina and mercury must be left in contact with each other for some time, and be submitted to a heat of about from 122° to 176° F, otherwise no notable difference from that observed with other metals will be remarked.—4° To ascertain the equivalent of mercury, the bichloride of that metal was dissolved in ether, dried and volatilized in a dry receiver; the needle-like crystals (soluble in alcohol and ether) thus obtained, gave by analysis.

1st Analysis.

	Grammes		Grammes		
Quantity of salt Employed ..	1·317	Quantity of mercury.	0 809	per cent.	73·87

2nd Analysis.

Ditto..........	2·3785	Ditto........	1 9035	Ditto....	73·82

In calculating the equivalent of mercury by that of chlorine 442·64, it was according to the first analysis 1251·02, and the second 1248·2, which is very near to 1250.9 obtained by MM. Erdmann and Marchand. The author likewise examined the two kinds of binoxyde of mercury, the yellow and red; the former obtained by adding soda or potash to a solution of bichloride of mercury; the latter by calcination of the nitrate of mercury, by boiling the solution of the acetate of the binoxyde, or by adding caustic alcalies to certain oxydo-chlorides. When anhydrous, they may be recognised by two tests—a cold aqueous solution of oxalic acid dissolves the yellow oxyde, forming a white oxalate; it has no action on the red oxyde; an alcoholic solution of bichloride of mercury changes the yellow oxyde into a black oxydo-chloride, as soon as the liquid is heated, but is without any action on the red oxyde. Very long ebullition may change the red oxyde into white oxalate and black oxydo-chloride, but these changes are not isomeric.

Oxydo-chlorides of Mercury present various hues—bright red, dull red, purple, violet, brown, deep black, &c., but notwithstanding these varieties of colour, analyses showed but two differences in the composition. 1° Hg Cl, 2 Hgo, being a bibasic oxydo-chloride. 2° Hg Cl, 3 Hgo, or a tribasic oxydo-chloride. The former is still black, the latter of an orange yellow—both isomeric.

On some proto-salts of mercury, and the ammoniacal products which result therefrom, by M. Jules Lefort. The salts examined by the author of this memoir were—the nitrate, the carbonate, the nitrite, the oxalate, the iodate, and the acetate. The formulas, calculated on the equivalent indicated by MM. Erdmann and Marchand, obtained with the nitrates were—

Neutral bi-atomic nitrate—$Az. O^5, HO, (Hg^2 O^2) HO.$

Acid—$Az. O^5, (Hg^2 O)^2, HO, + Az. O^5, 4 HO, \frac{HO}{2}.$

Same salt, anhydrous—$Az. O^5, (Hg^2 O)^2, + Az. O^5, HO.$

Intermediate nitrate—$3 Az. O^5, (Hg^2 O)^2, HO + Az. O^5, HO.$

this being a combination of the two first. As to the action of ammonia, the experiments and analyses of the author lead him to conclude that it does not differ from that obtained with potash; the precipitate is black or greyish, and possesses the property of whitening gold. The protochloruret of mercury alone gives, with caustic ammonia, a compound which is always the same, owing to the insolubility of the white precipitate almost equal to that of metallic mercury; with all the other salts the quantity of mercury increases in proportion to the solubility of the salt. With the proto-nitrate of mercury, ammonia forms a compound—*mercure soluble d'Hahnemann*, in which the proportion of the metal varies considerably; the results of the analyses performed by the author at different temperatures and after repeated washings, were:—

Prepared at 32° F.	Prepared at 32° F.
Washed eight times.	Washed sixteen times.
Mercury 83·42 per cent.	Mercury 89·47 per cent.
Prepared at 77° F.	Prepared at 77° F.
Washed eight times.	Washed sixteen times.
Mercury 84·94 per cent.	Mercury 91·11 per cent

M. Dutrochet read a report on two memoirs; the first on the tendency roots have to sink into the earth, and the force with which they penetrate, by M. Payer; the second on a peculiar physiological property possessed by roots, by M. Durand, pharmacien at Caen. The principal object of both memoirs was the penetration of roots into mercury. After analysing the two, the learned reporter gave the result of the experiments performed by the committee, composed of MM. de Merbel, Becquerel, A. Brogniart, Pouillet, and Dutrochet, in order to verify the facts of the penetration of the radicles in mercury, when the seed is placed in a small quantity of water on the surface of that metal. The seeds employed were those of *lathyrus odoratus*; the radicles never penetrated beyond one line, and sometimes not at all; the former took place only when the seed or radicles were adherent to the mercury.

On a modification of the trocar employed in the operation for hydrocele, by Dr. Guépratte, surgeon in the navy. This modification, intended to prevent the infiltration of the injected liquid into the cellular tissue of the scrotum, consists in dividing the canula into two parts, the one containing the perforator, and the other a spring, by means of which a species of valve may be pushed out and drawn in *ad libitum*. The trocar having been introduced into the tunica vaginalis, and the perforator withdrawn, the spring is pressed, and the valve forms a right angle with the canula, its outer surface being in contact with the serous membrane; the instrument is thus prevented from changing its place, until the valve is made to resume its former position.

Mr. J. R. Hind addressed a letter to M. Faye, *astronome adjoint* at the Royal Observatory, Paris, in which he states that he had arrived at some interesting results relative to the large comet of January last, and that he had been favoured by a series of observations made by Mr. Sims at Columbo, in Ceylon, on January 5th, 6th, 7th, 8th, and 11th, which were published in the notices of the Astronomical Society, by Dr. Peters, professors Schumacher and Challis. He mentions the result obtained by Gaun's method for any conic section, and that of his calculations of M.M. Mauvais, and de Vico's periodical comet.

Mr. Cooper, previous to leaving Naples, addressed his recent observations on M.M. Mauvais, Darcet, and de Vico's comet.

Academy of Medicine. Sitting of the 29th April.—M. Caventou in the chair. Dr. Brachet of Lyons, corresponding member, was present.

On the health of workmen in Tobacco Manufactories.—Discussion on Dr. Melier's report.—Dr. Bricheteau did not consider the emanations from tobacco as injurious as stated, since he has examined men who have worked in these manufactories for fifteen, twenty, and even thirty years, without being inconvenienced; on the contrary, they were preserved from certain diseases, for instance, from bronchitis and rheumatism; moreover persons who are constantly in smoking rooms or who are inveterate smokers, do not experience any peculiar ailments. Dr. Londe asked whether the reporter had examined whether the number of diseases had increased since the monopoly had been established, and whether sickness is as

prevalent where this does not exist?* Dr. Melior in reply to the various questions and objections that were made, stated, 1°. *Relative to the proporti n of sexes*, this varies according to the kind of work done; in the manufactory in Paris, there are on an average, 800 women to 500 men, and when it was asserted in the report, that the number of sick was greater among the former than the latter, this was not lost sight of; perhaps the mode in which the females are dressed contributes to this result, and it might perhaps be useful to modify it. *Relative to the wages*, which, as was justly observed, exercises considerable influence on the health of the workmen; at Paris it is for the men, to from 2s. 6d. to 3s., and for the women, from 10d. to 1s. 5d. *Relative to the ameliorations obtained since the establishment of steam engines.* In five manufactories they have not been established, and in these, diseases are of most frequent occurrence, and are most serious, especially ophthalmia. *Relative to the existence of amaurosis.*—It has never been observed in the manufactories in Paris, and is not noticed in the reports of the physicians of the other establishments. *Relative to the quantity of urine, and the frequency of micturition.*—Both exist, and are easily explained by the diuretic properties of the plant. *Relative to the amniotic liquid presenting the odour of tobacco.* This case was observed in the clinical wards of Professor Stoltz, of Strasburgh: it is not the only fact recorded, in which similar effects were remarked; thus Haller narrates one of a woman who took, while in the family way, a considerable quantity of saffron, and whose amniotic liquid was tinged with and presented the odour of this substance; Levret that of another, who, while in the same state was submitted to a mercurial course, and the same liquid whitened a copper plate; these facts are re-published by Baudelocque, Maygrier, and Professor Moreau. *Relative to the coloration of the skin.*—If the skin were simply stained, lotions would suffice to remove the tint, but as this is not the case, and as two years are often requisite ere it disappears, it is evidently a species of cachexia analogous to chlorosis, so much so that in both steel is given with advantage. *Relative to the habit*, the opinion emitted by Dr. Rochoux is correct. *Relative to the omission of hygienic rules*; this is not the case, since several were proposed by him, and adopted with evident benefit to the workmen. *Relative to the gases disengaged*, the effects are not produced by ammonia alone, inasmuch as this substance is mixed with nicotine. Finally, Dr. Melier refused to admit having treated Parent Duchatelet too harshly. He appreciated his works, and was his friend, but, he considered that he, (Parent Duchatelet) had a tendency to exaggeration, and that he was an optimist more from kindness than aught else, and that he could not adopt his opinion relative to the harmlessness of tobacco emanations. He also combatted Dr. Londe's additional conclusions After some further remarks from Drs. Delens, Gase, and the reporter, the discussion ceased. Dr. Gerardin proposed to request the minister to employ steam engines in all the manufactories. This proposition combated by Professor Adelon and Dr. Nacquart was rejected. The conclusions of the report were then adopted.

* This question was first raised by Jean Raimond, the witty writer of the *causeries hebdomadaires* in the *Gazette des Hopitaux*, who, by his humour and repartees often succeeds where more serious writers fail, from presenting the subject in too solemn a style. Speaking on this subject, he expresses himself thus: "In a hygienic point of view, there is a question completely omitted in the report; viz.:—Is the fabrication of tobacco in small quantities, as is practised by private individuals, as injurious to the workmen as when it is manufactured in large quantities? Have comparative researches been made? Have similar effects been observed in other countries where no monopoly exists? For if from this comparison it results that the diseases are more serious and more frequent when it is manipulated in large quantities, the Academy ought evidently to point out the fact." In conclusion, I cannot but engage persons so situated as to be able to study this important question, to publish their observations in scientific periodicals.—G. de B.

PROGRESS OF GERMAN MEDICAL SCIENCE.

By Sigismund Sutro, M. D.

Poisoning by Cherry Kernels.—The daughter of a widow æt. 5 years, ate a considerable quantity of the kernels of sweet cherries (prunus acium). Her brother (a few years older than herself), also ate some. After the lapse of a few hours symptoms of poisoning appeared. When the author was called the next day, he found the girl so comatose, that she could not be roused by any means, The eyes were closed, the pupils considerably dilated, the skin moist and hot, respiration exceedingly hurried, pulse small and quick, urine and fæces discharged involuntarily; the child very restless. A saturated solution (probably citric acid, with carbonate of potash) was ordered internally, and cold fomentations to the head externally; after a few hours, vomiting of a greenish mass ensued, and was followed by retching, which lasted till death; the body was spasmodically contracted backwards. The illness lasted forty hours. On the *post-mortem* examination, the stomach externally was normal, and internally rather swollen and reddened; the intestines were strictured and invaginated, but there was not any inflammation. The liver, spleen, and large vessels, contained black tar like blood. The body was not examined further. The boy, who had eaten fewer cherry kernels, became likewise ill, but recovered in the course of a month. An eruption, analogous to urticaria, came out on the fore-arms of both children; they were both perfectly well (according to the statement of the mother) before eating the cherry kernels, and no other cause for the attack could be assigned. The kernel of the prunus avium (cerasus nigra MM.) containing amygdaline, and developing prussic acid, with ethereal oil in the stomach, is a very remarkable occurrence, and one which ought to serve as a warning.—*Mertens of Wangrowcit in der Medic. Zeit. f. Heilkunde, Prussic.*

On the Effects of Blood as an Antidote to Arsenic.—The desire of discovering in poisoning by arsenic, an antidote which could be obtained and employed under any circumstances, led the author to institute the following toxicological experiments:—Arsenic having a great affinity to the constituents of blood, the author administered at noon to a well fed healthy dog nine years of age, three grains of arsenious acid dissolved in diluted milk, after the animal had been eighteen hours without food; a quarter of an hour after, eighteen ounces of blood, taken from a calf just killed, were poured into its mouth. Considerable perspiration and trembling all over the body ensued, then thirst, dejection, and tendency to vomiting. At seven o'clock P.M., the dog ate and drank freely, was lively, and apparently strong; neither vomiting, nor stool, nor urinary secretion, ensued during the night. The following day the dog was left quiet. On the third day six grains of arsenious acid were given in diluted broth, after fasting for twelve hours: within ten minutes twelve ounces of blood were poured in, the animal's struggles preventing a greater quantity from being administered. It drank a great deal of water. No other symptoms appeared than those perceived at the first experiment, viz., perspiration, exhaustion, and trembling. In the evening the dog was quite lively. A day's interval was allowed for his recovery, and on the fifth day he had nine grains of arsenious acid in diluted milk; after a few minutes nine ounces of blood were poured into its mouth with great trouble. The symptoms were the same as on the former occasion, together with the singular fact, that a pterygium of the right eye, with which the dog was affected, contracted itself, and disappeared the next day; the right eye was then as clear as the left. On the seventh day the dog received twelve grains of arsenious acid given in broth, and no more than eight ounces of blood could be injected; the perspiration was so considerable, that the animal appeared as if it had been bathed; the thirst was great. The animal howled constantly with a hoarse voice, and evacuated fæces and urine, which had not been the case in the former experiment. After the lapse of twenty-four hours, that is, on the ninth day, the dog had eighteen grains of arsenious acid, and about six ounces of blood. The dose was increased this time by six grains, because the author wished to close his experiments with the death of the dog. The effects were now very marked, great thirst, restlessness, convulsions, and complete prostration. At about eleven P.M., the symptoms of poisoning had almost disappeared; after some days the dog recovered almost completely with the exception of hoarseness in barking. In order to ascertain the organic changes produced by the large quantities of arsenic which had been introduced into the system, the dog was killed. Neither the pharynx nor fauces were inflamed nor spotted; the venous blood was gelatinous, the arterial coagulated and not quite red; the liver was very hard and fragile; the lungs were inflated, and covered with bluish spots in some places; they scarcely contained any blood; heart unaltered. The blood contained in the heart was gelatinous and black; this was particularly the case in the right ventricle; stomach unaltered externally, thrown into deep folds, much inflamed internally; pylorus normal. Duodenum, ileum, and colon were also inflamed, and filled with digested food. In order to ascertain whether the arsenic had not entered the blood or the brain, the author collected the blood of the heart, evaporated it to dryness, powdered it, and mixed a part with an equal quantity of carbonate of potash, and half the quantity of coal powder, and to his great surprise he obtained two grains and a half of arsenic by sublimation. The other part of the dried blood was used for analysis by a liquid process, and arsenic was likewise obtained; the brain was also dried and powdered, and mixed with carbonate of potash, and again one grain and three quarters of arsenic were obtained; the liver,* muscles, &c., would also have been analysed in a similar manner, if the body of the dog had not been taken away during the night, and thrown into the river without the author's knowledge. Though the experiments appear imperfect in consequence of the urine and perspiration not having been analysed, still the author suggests in cases of poisoning by arsenic, to use the blood of a freshly killed animal as an antidote, if no medical treatment were readily obtainable. Should the nauseous character of the remedy be a great objection, it would be greatly removed by the patient having his eyes bandaged while taking the blood.—*Franz. Apoiger in Buchner's Repertorium.*

Observations of Buchner.—Apoiger's experiments have furnished a remarkable result, confirmatory of his theory, and of the highest importance in medical practice. It is well known that vomiting, and even death, is easily induced in dogs, by administering a few grains of arsenic; it must then be found exceedingly surprising, that the above-mentioned dog perspired so freely after drinking blood, but did not vomit, though the poison was absorbed into the circulating fluid; probably the arsenic formed a combination of proteine in the stomach with the blood. Similar experiments ought to be instituted with serum of blood and with albumen. If these combinations of proteine are found to have a less favourable affect, the specific efficacy must be ascribed to hæmataurine.

Semina Taxi Baccatæ as a Substitute for Digitalis.—Martin concludes from Dr. Rompinelli's experiments, that the seeds of taxus baccata produce a similar effect to, and may therefore be substituted for foxglove; the fleshy mallow enclosed in the seeds is inefficacious; the constituents of the seeds are, according to Martin, etherial oil, of a turpentine like smell, fat oil, a green very bitter resin, sugar, albumen, sulphate of lime, and vegetable fibre.—*Buchner's Repertorium.*

Carduus Nutans as a Remedy in Ascites.—From the following cases reported by Dr. Osberghaus, the Arabian thistle is in high reputation in the environs of Cologne. A young man of about thirty years of age, passionately fond of shooting, was, after frequently taking cold, affected with gout, later with hemorrhoids, and, lastly, with abdominal dropsy. After the inefficacious employ-

* This is greatly to be regretted, since probably the largest quantity of arsenic would have been discovered in the liver.

ment of several diuretics, Dr. Osberghaus was consulted and ordered a warm bath, with ash lye, and the internal use of elder-flower tea; a profuse perspiration broke out, with a more abundant discharge of urine, and the dropsy disappeared. When the health was restored, the patient again gave himself up to his former passion for shooting and drinking, and after the lapse of ten years the ascites re-appeared; the baths and diuretics were again employed but in vain, so that abdominal paracentesis was resorted to, and ten quarts of water were discharged; the water re-collecting, tapping was performed at four different periods. In this unhappy state the patient was advised by his acquaintance to try the domestic remedy, known under the name of Arabian thistle (carduus nutans), which is found everywhere as a biennial plant on sterile places, in hedges and ditches, and is distinguished by the over-hanging (or nodding) blossom-heads, with felting stalks; a handful of this thistle dried and cut, and boiled with a quart (thirty-two ounces) of water was taken by tea-cups full, and the dropsy finally disappeared. When the decoction of the thistle was discontinued, the urine was discharged more sparingly, and the abdomen began to swell, it was therefore necessary to continue the remedy for some time, and to use tonics after it was discontinued. The dropsy did not recur. The efficacy of carduus nutans in ascites has been confirmed by frequent trials. Professor Buchner mentions the following interesting case, which gained a great reputation for the Cortex rad. Frangul., recommended by Dr. Gumprecht, as a specific against hemorrhoids, in a former number of the *Repertory*. A citizen of Munich, who had suffered with gout and hemorrhoids, was at last affected with dropsy; the physicians gave little hope of recovery. A reader of the *Repertory* reminded the patient of the article in question—the rhamnus frangula (black alder) was consequently obtained, and administered to the patient in the form of decoction according to Dr. Gumprecht's prescription. The dropsy was absolutely cured by means of this remedy, and the fortunate convalescent of course, spread, its renown as much as possible amongst the public; he is, however, said to have lately had a relapse.—*Ibid.*

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN SCIENCE.

(The following are the principal articles of interest to our readers in two numbers of the *Medical Gazette.*)

Rheumatic Caries Vertebralis.—Mr. Solly believes that this disease is local, that it is, in fact, mollities rubra et fragilis, produced by rheumatic inflammatory action. The treatment he advises is rest in the recumbent posture, leeching, and the exhibition of calomel and the iodide of potassium in small doses.

Treatment of Hydrocephalus.—Dr. Blackmore is of opinion that venesection or arteriotomy would, in most instances of this disease, prove far more beneficial than the local abstraction of blood by leeches. He has bled a child eighteen months old, from the back of the hand, where alone a vein could be found, to an ounce and a half, with the best effect; and has seen stupor and obstinate febrile symptoms instantly relieved by a single bleeding from the jugular vein, when the most active medicines had been given in vain. Next in value to bleeding is the cold affusion, or a long-continued stream of cold water on the head, or applying a cooling lotion with a large paint-brush, which is preferable to laying a wet sponge or cold cloths on the head, the refrigerating effect being certainly greater. A spirituous lotion is not always so safe as plain vinegar and water; as the alcohol in the lotion has seemed to induce delirium. Of sedatives, Dr. Blackmore thinks colchicum preferable to digitalis; the latter remedy appears sometimes to have been mischievous in its action. In cases beyond the age of infancy, when there is much delirium with a tense pulse, narcotics have been given; they are safe and often highly useful after proper bleeding; but at the beginning of the disease, or during the height of the inflammation, they are decidedly hurtful; under such circumstances Dr. Blackmore believes the favourite combination of opium, with calomel, often unadvisable:—antimony with a purgative, and the steady effusion of cool water, are the best means of improving a hard, quick, sharp pulse in children, when bleeding cannot be carried farther. In the latter stages of the disease, when much mercury has been given, and the system is irritable, henbane or muriate of morphia is safe and beneficial; but when opium has been given, having appeared to be required by the intermittent headache, its effect has been a matter of regret. The extensive pustulation of the scalp by antimonial ointment has appeared a powerful means of lessening stupor; but its irritant action has induced delirium. Mercury, employed so as to affect the system, without previous bleeding, has not been successful. Its use by inunction, with small doses of calomel, has been more satisfactory than the enormous quantities of the latter which are sometimes given. Costiveness being a predominant symptom, violent doses of drastic purgatives are sometimes given with an unsatisfactory effect; the repetition of small doses of calomel and gamboge, or calomel dropped on castor oil, with a senna clyster, and cold affusion on the spine, are better means of acting on the bowels. It is not always advisable to seek to arrest the vomiting; it may be regarded as an useful criterion of the state of the brain, and has seemed to relieve the inflammatory tension of the vascular system. If it be thought right to arrest it, ether on the epigastrium is safe and efficacious. The spasms in the latter stage of the disease are relieved by giving a little spirit of ammonia, and an opiate, applying at the same time on the spine a cloth wetted with tepid vinegar; or by dropping elder flower water on the head, and administering a turpentine enema. For the depression of the circulation that sometimes attends the outset of the disease, cold affusion on the head, and a stimulant pediluvium are the best cordials. A state of exhaustion also sometimes occurs in the progress of the malady, and death is threatened by a sinking of the vital powers; in one such instance, in a boy seven years of age, Dr. Blackmore gave half a pint of sherry in a few hours with success. In such a state, of course, the cordial should be given in very small doses, repeated at short intervals. In a case where unequivocal symptoms of effusion seemed to forbid a hope of recovery, the child was restored by a combination of purgatives, mercurials, counter-irritants, and narcotics.

Eczema.—Mr. Phillips has published two cases of inveterate eczema successfully treated by the local application of warm water, and the internal exhibition of liquor arsenicalis. The first and more severe case was one of six years standing; the skin was greatly thickened and hardened, and it was intersected in all directions by deep fissures. It had been treated by various methods, with but temporary relief. It completely yielded to the above treatment, and within four weeks from its commencement the skin was as soft and as natural as that on any part of the body. The patient did not leave the hospital for a fortnight after the cure, in order to be assured that it was complete.

Epilepsy.—Dr. Blackmore points out among the peculiar phenomena of epilepsy, the spontaneous subsidence of coma after the fit; its persistence through a long life, without much disturbance of the general health, or of the mental faculties, even when congenital, or acquired in early childhood: its becoming a periodical and purely spasmodic disease, the comatose part of the affection having subsided, in some cases where it has occurred in the adult age; and that in some cases, after having become an established habit for many years, even after puberty, it entirely wears itself out. It occasionally, but rarely, causes hemiplegia: when habitual, and the fits increasingly frequent, it may end in fatal apoplexy. When properly treated before the age of puberty, it is often cured; and even when acquired after puberty, and become habitual for years; but when it appears in early childhood, and persists to adult age, it is very seldom cured. With respect to the recurrence of the fit, if the exciting cause is recent, and not inevitable, if the head does not shew irregular ossification, and if there is no family pre-disposition, there is reason to expect its non-recurrence, if proper precautions are taken. Probably no other disease is so dependent for its recurrence on the habits and physical circumstances of the patient. The coma may be distinguished from that of apoplexy by the character of the spasms, of the breathing, and the pulse, with the duration of the stupor. When consequent on other diseases, the prognosis is more serious than in the simple and primary affection; yet even when succeeding to apoplexy itself it is not incurable. Recovery is seen in young subjects, although coma has continued for eight hours, and after the vital functions have begun to fail. Hope is to be founded more on the nature of the predisposing and exciting causes than on the actual symptoms of the paroxysm. The proximate seat of the irritation is the corpora striata, the medulla oblongata, and the encephalic portion of the spinal chord; and this irritation is often the effect of disease in other portions of the encephalon, the influence of which in inflicting pressure on the basial parts is easily understood from the structure of the head. Various cases show, indeed, that disease in the same remote portion of the brain may occasion either apoplexy, hemiplegia, or epilepsy; the same sort or degree of influence is therefore not always communicated to the medulla oblongata and spinal chord; or, according to modern anatomical views, the cause of the difference in the effect is, that in epilepsy the organic portion of the spinal chord is irritable as well as the sensorium, and not in the hemiplegiac or apoplectic cases; and in the former disease, also, the nervous origin of motor power is more affected than that of the sensorial functions. The morbid appearances are, a general enlargement of the arteries and veins, with fulness of blood; sometimes a general softening of the brain; an encysted abscess in the hemispheres, or suppuration at the crura cerebelli; induration and tubercles; exostosis of the interior of the skull. The most constant, and, in a practical view, the most important, condition which may be regarded as the proximate cause of epilepsy, is excited circulation in the encephalon: this state is either transient or more prolonged, and constitutes an inflammatory condition, of which the convulsions are sometimes the first symptom. It is also primary and idiopathic, or symptomatic and secondary on irritation in other organs, particularly the gums and intestines in children, and the uterus and nerves external to the head in the adult. Confirmed habitual epilepsy has probably always its origin within the head. Morbid congestion in general is spoken of as active or passive, *i.e.* attended with high action of the vessels, or with atony and unirritability. Dr. Blackmore is not disposed to regard the latter state as capable of producing epilepsy, and he refers the attack when it occurs after exhausting diseases, or in weak constitutions, to a fulness of blood in the brain, with strong action of its vessels: an action strong, if not absolutely, yet relatively to the general powers of the vascular system in the individual patient, and by which the momentum of the encephalic circulation is for the time increased. The treatment during the fit should consist in the use of cold affusion; if bleeding be afterwards practised, it should be to a far less extent than in apoplexy; when excessive, it has only been the means of substituting one form of convulsions for another, or of inducing worse consequences. In that form of disease from a stroke of lightning, or a sun-stroke, or from a large quantity of spirituous liquors taken at a draught, experience shows that the best treatment consists of the cold affusion, followed by an emetic and ammonia, as soon as the power of swallowing has been recovered: bleeding in some such cases has been fatal. Besides the cold dash, an enema of turpentine is alone required in most cases. Compression of the carotids also has been found useful. In the intervals of the fits, the most generally curative treatment, in a vast number of cases has been the antiphlogistic, either evacuant or sedative. Small bleedings and cupping, shortly before the period of the return of the paroxysms, have had a most salutary effect, while profuse bleeding has served to make the returns more

frequent. Purgatives are especially valuable; *e. g.* elaterium and croton-oil. In relaxed habits a combination of colocynth with the gum-resin of Cornel has succeeded well. The oil of turpentine is a most useful adjunct in these cases to castor-oil. Emetics, particularly sea-sickness, are safe and wholesome. An issue in the calvarium has been of use in some cases. Sedatives, as colchicum and digitalis, have been often successful; and, when incautiously given, productive of equal mischief. The refrigerant sedatives, and the shower-bath, deserve more commendation; and as a means of keeping the head cool by night, the air-pillow is not contemptible. Terror is a sedative not easily managed. In many cases of chronic epilepsy, on the other hand, the most successful treatment is not evacuant or sedative, but tonic—not that tonic plan which fills the vessels with blood, but that which increases their contraction, and equalises the general circulation. Of this class, the more successful is turpentine, in small and frequent doses: the sulphates of copper and of zinc, and the nitrate of silver, appear to act similarly to turpentine, but not so efficaciously. When the fits recur in the night, the habit may be broken by an opiate at bed-time, and by the patient being awakened and leaving the bed. *Concubitus rite et legitime peractus* has proved a remedy, just as its abuse has been one of the worst excitants of the malady.

INCISION OF THE CALVARIUM.—Dr. Blackmore strongly recommends the making a deep incision in the scalp, and allowing the wound to bleed freely, in the treatment of spasmodic affections. He says he has used it several times with gratifying success in spasmodic cases of an encephalic origin, as well as in hemiplegia and mania. When there has been either a fixed pain in the head, or a tender portion of the scalp, so that gentle percussion has induced excessive pain, a convulsion or hysterical fit, his experience has shewn that the bleeding from the free incision is a far more powerful remedy than any other mode of depletion. The practice should not be confined, as formerly, to cases of disease in the pericranium, nor should it be adopted merely as a last resource in chronic affections of the brain and its membranes, or as a first step to making the enormous issue lately recommended. This latter Dr. Blackmore especially condemns. The incision should be about three inches in length, dressed with turpentine, and an emollient poultice applied for a few days afterwards.

PERICARDITIS AFTER SCARLET FEVER.—Dr. Snow believes that this disease arises only as a consequence of the renal disease, which is apt to follow scarlet fever, and that it does not occur at an early period of the exanthema.

EDEMA OF THE GLOTTIS.—Mr. Illingworth narrates a case of this disease caused by the local irritation of a hot potatoe, and cured by bleeding, the application of leeches, with calomel, aperients, and salines.

PRESBYOPIA.—A case of presbyopia which occurred suddenly in a boy, eleven years of age, is published in the *Northern Journal of Medicine*. The eyes were apparently healthy, and of the normal character in every respect, and no cause could be traced for the attack. The expectant plan of treatment was adopted by Dr. James Hunter, under whose care the boy was placed, and after the lapse of about six weeks, the sight began to improve, and in ten days was perfectly restored.

PERICARDITIS.—Dr. Durrant, in the *P. Med. Jour*, says—The consideration of the physical diagnosis of pericarditis is facilitated by a division into periods, or stages, according to the pathological characters, from which the distinctive phenomena derive their origin. *1st stage.—Effusion of Lymph.* Inspection.—Impulse of the heart visibly increased and jerking. Application of the Hand.—Heart's action impulsive and abrupt, accompanied frequently by a vibratory tremor; pain excited both by pressure between the intercostal spaces, and also by forcing the diaphragm upwards towards the pericardium. Auscultation.—In the earliest stage of the inflammation, prior to the effusion of lymph, the movements of the heart are quick jerking and tumultuous; its rhythm often becoming irregular and intermittent; a feeble and dry rustling sound, not necessarily permanent, is at this period occasionally audible. As the disease advances, and lymph becomes poured out, a friction sound, more frequently double, is heard accompanying both sounds of the heart; of greatest intensity during the systole of the organ, with its maximum generally over the apex. Percussion.—Slightly increased dulness from congestion of the heart, and effusion of lymph. *2nd stage.—Effusion of Fluid.—Inspection.*—In extreme cases, præcordial region rendered somewhat prominent by the circumscribed filling up of the intercostal spaces; movements of the heart invisible.—*Application of the hand*: No vibratory thrill; impulse feeble and indistinct.—*Auscultation*: Sounds of the heart, weak, deeply seated, and undulating; friction sounds diminished or extinct; reappearing occasionally, if the patient be directed to incline the body forwards; influenced also, in some measure, by lateral position.—*Percussion*: If the amount of fluid be considerable, the extent of dulness over the præcordial region is greatly increased, varying with the position of the patient, for which reason, a carefully conducted comparative examination, both in the erect and horizontal posture, must not be neglected.—*Signs of Resolution.—Auscultation*; Cessation of the attrition murmur; increasing regularity, and quietude of the heart's impulse and rhythm, unaccompanied by inordinate jogging and tumbling action, indicating adhesion. If serous effusion have existed, the friction phenomena may again return, as the result of its absorption, and sooner or later, ultimately cease.—*Percussion*: Extent of dulness gradually diminishing, until it reach its normal limits. *Adhesion of the Pericardium*: Signs doubtful, rendered, however, probable, if the previous history of the case afford evidence of a former attack of pericarditis. *Inspection*: Impulse of the heart abrupt, forcible, and very visible; intercostal spaces occasionally drawn inwards during its contraction; situation of the heart within the chest apparently stationary, and uninfluenced by the change of posture. In some instances, in consequence of adhesions, it appears higher than natural, as a result of which the præcordial region is rendered slightly prominent. *Auscultation*: Cardiac movements, abrupt, tumbling, jogging, or forcibly struggling; often rendered painfully acute, by their proximity to the ear. The co-existence of a bellows murmur, together with the phenomena peculiar to enlargement of the organ, not unfrequently obtains. *Percussion*: Abnormal dulness if the false membranes be thick and firm, extending in proportion to the increment of the heart itself. *Observations*: Notwithstanding the usually well-defined characters by which the physical phenomena of inflammation of the pericardium, as well as the lining membrane of the heart, are accompanied, and the amount of success which generally attends early, and decisive treatment, the number of cases of damaged heart, connected with rheumatism, especially among the young, which daily force themselves upon our attention, proves either that assistance is not sought until the disease has effected irreparable mischief, or that, in many instances, the important complication of heart affection is still overlooked at the only period, during which, in a curative point of view, remedial measures can alone avail. Rheumatic pericarditis seldom obtains without the concurrence of inflammation in the interior of the heart. In the event of a rapid and extensive accumulation of fluid within the pericardium, by which approximation between its two surfaces is prevented, the murmur of attrition is often preceded by a bellows sound, under which circumstances the latter sign, in connexion with dullness on percussion, becomes the most direct index to the supervention of the pericardial disease. Pneumonia, bronchitis, and pleurisy, are enumerated by authors as being occasionally liable to be confounded with pericarditis. Between the two former affections, and inflammation of the pericardium, a properly conducted and sufficiently careful examination should suffice to remove all doubts. The diagnosis between disease of that portion of the pleura, situated immediately over the heart, and chronic inflammatory affection of the pericardium, will, however, sometimes give rise to considerable hesitation in the mind of the auscultator. The greater influence of the cardiac movements in augmenting the attrition sound of pericarditis, and the similar effect produced by a deep inspiration on the friction phenomena of pleurisy, together with the previous history and general symptoms of the two diseases, will assist in substantiating a correct diagnosis. The seat of the dullness, with the normal character of the breath-sound over the postero-inferior part of the chest, will sufficiently distinguish pericardial from pleuritic effusion. The occurrence of cerebral symptoms in the course of an attack of acute rheumatism, should at once direct attention to the physical condition of the heart, and its investing membrane.

HÆMORRHOIDAL NEEDLE.—Under this name, Mr. Borlase Child, surgeon to the City Police Force, in a communication with which he has favoured us, describes an instrument which he has made for the purpose of applying ligatures to small tumours in the vagina and rectum, which he thinks is particularly adapted for the removal of hæmorrhoids, an operation not easily effected, when the tumours are not very prominent, have broad bases, and are situated very closely together. The ordinary mode of procedure in such cases is to pass the ligature around the tumour, with the right and left index fingers either aided by a tenaculum or not, as the operator may deem expedient. With the utmost precaution it sometimes occurs that the attempts to complete the operation are embarrassed by the constant slipping of the ligature, or, what is still worse, the operation may prove unsuccessful from the ligature embracing a portion only of the hæmorrhoid. Such accidents, in Mr. Child's opinion, are less likely to occur when the hæmorrhoidal needle is resorted to, for it enables the operator with great facility to keep the silk in close contact with the base of the tumour, and when two or three are close together and are situated high up the rectum, the ligature is readily passed between them. The instrument is of very simple construction, and in shape is somewhat similar to a button-hook; on its under surface is a groove for the reception of the silk, which latter must be well waxed before it is used; at each extremity is a slit or notch, for the purpose of nipping the silk and retaining it in its proper situation. The operator carries the needle, previously threaded, behind the tumour, with the handle slightly raised in order that the groove may be brought to bear immediately upon its base; he then gives it to an assistant to hold, directing him to keep a steady and firm pressure downwards and outwards. The operation is then completed in the ordinary way, the ligature as it is tied releasing itself from the groove of the needle. A modification of the same instrument might, he thinks, be advantageously resorted to for the removal of polypi and other tumours of the uterus.

THE TREATMENT OF SCROPHULA.—Dr. Sutro has sent us a communication on the treatment of scrophula, in which he defines the malady, as irregularity of the functions of the lymphatico-glandular system, causing an improper assimilation of lymph, and consequently imperfect nutrition, with obstruction and accumulation of lymph in the lymphatic vessels, irritation, and even local inflammation, and in consequence glandular tumours, induration, tubercles, and suppuration, beginning in the glands, and gradually invading the other organs. The scrophulous constitution is shewn by an unusually large head (particularly the occiput), a short, thick neck, compressed temples, broad maxillary bones, bloated face (particularly the upper lip and nose), light coloured hair, white tender skin, with red cheeks, generally blue eyes, and large pupils; the whole body fat, and apparently well-fed, but the flesh rather lax and spongy to the touch, the abdomen large, frequent bleeding at the nose, a tendency to an abundant secretion of mucus in the alimentary canal, to helminthiasis, and blenorrhagias of different organs; irregular stools; premature development of the intellect, with simultaneous retardation of the bodily powers, as in dentition, walking, &c. The symptoms of scrophula consist of glandular

enlargement in different parts of the body, which may either continue for years in the indolent state, or else may take on inflammatory action, suppurate, and lead to the formation of scrophulous ulcers, which secrete a watery acrid ichor : chronic inflammation of the Meibomian glands, frequent muco-purulent discharges, principally from the ears, uterus, or lungs ; eruptions on the skin, chiefly in children, distended tense abdomen ; cold abscesses, and disease of the osseous system, such as spina ventosa, and caries. Cretinism he regards as an indication of general scrophulosis of the whole system. The consequences of the disease are, atrophia mesentorica, tabes scrophulosa, phthisis tuberculosa, hydrops (particularly ascites and hydrocephalus), cancer, etc. Scrophula is generally a disease of development, beginning in childhood, and terminating at puberty ; but it sometimes commences at that period of life, and females occasionally become subject to it, after the cessation of the catamenia. It may be called into action by accidental causes, if the predisposition exists. The remote causes are scrophulous, or debilitated parents, sickly, scrophulous, or syphilitic nurses, artificial feeding during the first year, impure, moist, animalized air, want of cleanliness, bad, indigestible food, effervescing vegetables, sedentary life, want of exercise, premature exertion of the mind, strong astringent remedies, injudicious use of narcotics, etc. In respect to treatment, therefore, the remote, as well as the proximate causes, must be counteracted. With this view, an improved diet, proper exercise, fresh, pure air, and great attention to cleanliness, are strongly recommended. The medicinal remedy advised by Dr. Sutro is the exhibition of cod-liver oil (oleum jecoris aselli), which he regards as a specific in scrophula, and says it gently promotes the secretions of the skin, kidneys, liver, and bowels, on the one hand, and the functions of the lymphatic glands and absorbents on the other. He is uncertain whether the effects produced by it on the organism are to be referred to the animal gluten, resin, oil, or iodine it contains, or to their combined action. Its use must be persisted in for months, and appropriate treatment adopted at the same time to combat special symptoms. With regard to the unpleasantness of the taste of the medicine, he says, that although very disagreeable to healthy persons, it is not so to those labouring under this disease ; scrophulous children take it with the greatest ease and indifference. The dose is from one to two tablespoonsful (teaspoonsful for children) twice or thrice a day. The best time for its exhibition is one hour after breakfast, and several hours after the other meals. A little peppermint-water, or coffee without milk may be drank afterwards. Nine cases of scrophula out of ten, Dr. Sutro is convinced, will be cured by this remedy, and he details one from his own practice, in which a successful result followed its use.

NOTICES TO CORRESPONDENTS.

A. R. B. A Subscriber.—*Such Graduates will doubtless be allowed to register under the new Bill.*

Dr. Browne's *interesting "brochure" has been received.*

A Surgeon's Assistant, *could lose nothing by making the statement he suggests. We are, however, unable to foretell the result. Our Correspondent can receive no useful advice except from one who has made some advance in the alchemy of life, and will communicate his secret.*

Mr. Haydon's *letter has been received, and shall not be overlooked.*

X. Y. Z. *will oblige us by sending the abstract.*

A Constant Reader.—Paris. *The new Bill is not likely to cause any difference in the terms of graduation.*

An Enquirer.—*Edinburgh shall be inserted in an early number.*

Mr. Gill *has no remedy.*

Lucius *on Medical Reform, in a collected form, shall be noticed by us in a more kindly way than our Correspondent appears to anticipate.*

F K. S.—*There is some doubt about the question, but the best opinion is, that any man is legally a surgeon that pretends to be one.*

A Student.—*A letter should be sent to the Secretary to the Senate, Sir W. Hamilton Bart. He will return a courteous reply. The Dean of the Edinburgh Faculty (University) is Mr. Syme.*

A Member.—*Mr. Upton is the Clerk of the Society of Apothecaries. All the matters touched on, are completely under his direction. We think that the complaint originated in a complete misunderstanding.*

D. F.—*A reader may find the information he asks for in any almanack.*

A Tyro.—*The explanation of Mr. Stanley to the Medico-Chirurgical Society was conclusive. We see no good in re-opening the matter.*

We have given J. H's letter a very full consideration but without changing our opinion. We will not decry German or French Medical Schools, but God forbid that we should ever remain content under any system which despatches a student to the Continent as the only means of getting a good medical education. Our mis-governments have done much, very much to injure and degrade science, but let us still hope that of all the subjects of human study and enterprize, medicine is not the sole one in which England is in the rear of the nations. There can be no improvement without schools, no schools without students, and therefore we say again no foreign diplomas! It is the place of England as Milton long since said to teach the nations : not to be their pupil.

Justitia *sends us a letter, calling attention to the defects of the Bill, and pointing out the injustice done to General Practitioners by the recent Charter. He remarks very correctly, that Sir James Graham might achieve a high distinction by liberally dealing with the question of Medical Reform.*

X. Y. Z. *is thanked, but we are really vain enough to hope that we need no such defence. We can pardon readily the ill temper of a contemporary when we know it is traceable to no cause but the damage inflicted by our success. There is no reader, that has read our columns, who can deny that, at all hazards, we have supported each Government proposition (promising) the adjustment of our wearying and mischievous strifes with all the anxiety compatible with the discharge of our primary duty to the profession. We have done a justice to the Government measures under all their phases which we believe no other journal has exemplified ; and in the alterations that have recently occurred, our vanity sees something very much like a tribute of homage to our temperate and discriminating objections.*

P. S. *is right, the hon. member did make a mistake as to his ability, and a very serious one. Like one of Astley's performers he thought to ride at the same time two horses, Sir James Graham and the profession. He has lost footing on both ; he is kicked to the earth. Few men can sit on two stools without the breech reaching the ground. Will P. S. favour us with the article he refers to?*

Medicus.—*All will register at the Central board in London.*

Dr. Hooper's *paper on hydrophobia has been received, and will be inserted.*

Anxius.—*All M. D's. with degrees procured through examination, will register as physicians, and consequently will bear the legal title, Doctor. They can practise as General Practitioners, but cannot enforce any charge legally. Our Correspondent will not be molested by the Bill.*

The list of newly made physicians sent to us, and published, April 26th, is not quite correct. For George Rope read George Rogers : omit the name of Mr. Leman Bristol, and insert that of Edward Josh. Staples.

E. M. C.—*We do not conceive that the new Bill will, in its final shape, have any retrospective action of an injurious tendency on Medical Students. The Council of Health which will supervise the curricula of study and scale of fees will not of course raise them to the injury of pupils actually "entered" ; and on a proper representation, which will not be wanting, the Bill will doubtless be made to provide specially against any possibility of an opposite course being adopted. We shall on an early day consider the whole Bill in its relations to Medical Students.*

M. N.—*We do not touch general politics.*

We are sure H. would not ask for slips of his article, if he knew the extreme inconvenience compliance with his request would cause us.

An Old Reformer *is mistaken, at least, on the question of* consistency. *Sir B. Brodie carefully propounded, in almost the same words, the same scheme of Medical Reform before Mr. Warburton's Committee in 1834, that he has endeavoured to carry out in the Charter and New Bill. Subsequently he is said to have announced them in the two celebrated articles in the* Quarterly. *His best views are the question of Medical Education, where he is most at home. He is nearly always wrong where the excellence of a measure depends much on the feelings with which it may be received, or on its effects in some nice complication of circumstances not very palpable. With all his large practice, and frequent approximation to members of the Profession, he understands little of their real feelings and opinions. In fact, it is not given to man to be at once Eustachius and Lycurgus. We look to this incompatibility, rather than to the worse feelings suggested by our Correspondent, as the source of his ill-success. The letter of an old Reformer in the present stage of the Bill could do no good.*

A Constant Reader.—*There is no institution of the kind to our knowledge so supported.*

A Medical Student.—*Several pencillings are in our possession, but are delayed by press of medico-political matter. A pencilling of Mr. Pennington, the patriarchal president of the National Association, will be one of the first.*

An Enquirer.—*The difference originated in the best of causes. The number of our stamped copies are more than quadruple, those of our contemporary. Mr. Churchill does not deny the fact.*

M. D.—*Our lists of new books have unavoidably fallen into arrear. We shall, however, bring it all up in an early number.*

The communication read at the last meeting of the Royal Medical and Chirurgical Society was from the pen of Mr. Ilott, of Bromley, and not of Mr. Scott.

N. S. N.—*The application of a blister may be of service in causing absorption of fluid effused into the cavity of a joint, but its utility in cases of enlargement of a bone is doubtful. It may aggravate the disease, if there be any tendency to the heterologous formations in the system.*

T. T., *and several other Correspondents, will be answered in our next.*

A Handsome Portfolio *for holding the "* Medical Times.*"—very desirable to those who would keep the numbers clean for binding, and easy of reference—may now be had, by order of any Bookseller, or at the Office, price 5s.—An allowance is made to the trade.*

THE MEDICAL TIMES.

SATURDAY, MAY 17TH, 1845.

Ourselves and children,
Have lost, or do not learn for want of time
The sciences that should become our country ;
* * * And my speech entreats
That I may know the let, why gentle peace
Should not expel these inconveniences.
SHAKESPEARE.

Our readers learnt from us, a short time since, that a Deputation,* formed of Members selected in equal parts from the Society of Apothecaries and the National Association, was appointed with full powers to treat with Sir James Graham on the question of the New Charter of Incorporation. It is now our pleasing duty to announce, as the result of these negociations, the important fact, that *Government have offered such a charter as the Committee have felt it their duty to accept.* We proceed to detail, on the authority of the deputation itself, the principal arrangements which affect more particularly the body of General Practitioners. The College will be incorporated under the title of "The Royal College of General Practitioners in Medicine, Surgery, and Midwifery." Two of its Members will sit on the Council of Health. Its letters testimonial will entitle the holder to registration as a General Practitioner in Medicine, Surgery, and Midwifery. The College will itself prescribe its own

* The Deputation consisted of Messrs. R. R. Pennington, John Bacot, John Ridout, James Bird, Henry Ancell, and R. B. Upton, the Solicitor to the Deputation.

curriculum, and the nature and extent of its examinations subject, like other Colleges, only to the Council of Health. It shall have liberty to appoint for Examiners, whom it pleases, in or out of the class of General Practitioners. Preliminary examinations will be held by a Board of Physicians and Surgeons of all *students* beginning their studies, who shall all undergo precisely the same sort of examination, and shall derive from the *liceat* then conferred no right to practice. After this examination, students must decide on the nature of their future practice.* If they enter to become Physicians, they will have to conform to the regulations of the College of Physicians, and may be examined at 26. If as Surgeons, similarly under the College of Surgeons, and if as General Practitioner under the College of General Practitioners. No candidate for final examination, either as Physician, Surgeon, or General Practitioners will be admitted, who cannot prove that he has given five years to the study of medical science. General Practitioners will be left eligible to all public appointments they may now fill. The penal clauses in the Act of 1815 will be transferred to the new College, and none but General Practitioners can claim the privilege of Apothecaries. Such are some of the principal arrangements which have been come to, and in reference to which the deputation express a confident hope, that they will generally meet the sanction of their medical brethren. They believe, that they offer a favorable augury that an understanding may at length be come to which shall lead to a peaceful adjustment of our many differences.

Though an understanding has been thus come to by the Committee with Sir James, and though it is understood that the Charter in the worst hypothesis, will contain enough to make it worth the Profession's acceptance, it would be a great mistake to suppose that their negotiations are at an end, or that they will cease to exert their influence to effect the further modifications the well-being of the class of General Practitioners require. Nay, we go further. If it should turn out when the Bill is printed, that the concessions of Government are not as complete or satisfactory as the deputation imagined, and that they fail to secure the approval of any large portion of their constituents, we are quite certain the Committee will show themselves faithful to their trust, and respectfully announcing the circumstances to Sir James Graham, decline to participate in any settlement repudiated by those whose confidence they enjoyed, and whose power they exercised.

To show that we need anticipate no such unpleasing result, we now proceed *to announce precisely what are the* ALTERATIONS WHICH SIR JAMES GRAHAM HAS INTRODUCED IN HIS BILL.

Clause 1, repeals the 3rd Hen. 8, cap. 11; the 5th Hen. 8, cap. 6; the 32nd Hen. 8, cap. 40; 32nd Hen. 8, cap. 42; 1st Mary, sec. 2, cap. 9; 6th and 7th Will. 3, cap. 4; 18th Geo. 2, cap. 15 (making surgeons and barbers of London separate corporations); a portion of 40th Geo. 3, cap. 84; the whole of the 55th Geo. 3, cap. 194 (the Apothecaries act), with the 6th Geo. 4, cap. 50, sec. 2.

2.—Constitutes the Board of Health, to which two members are added, chosen by the College of General Practitioners, and one, a member of the Senate of the University of London, to be chosen by the Senate. Her Majesty will now appoint but four members.

3.—Her Majesty will appoint all the members of the *first* Council of Health, except those sitting *ex officio*. The members subsequently chosen by the Colleges or University of London, will go out of office after three years, in an order to be fixed by her Majesty.

4.—Official Members remain in the Council of Health during the term of their offices as before, and Crown Nominees during her Majesty's pleasure.

5.—Vacancies in *elected* members must be supplied forthwith; but her Majesty's sanction will be necessary to confirm all such elections. The term of office will be three years, but members will be re-eligible. No president, vice-president, or examiner of any of the Colleges will be qualified to act on the Council.

As in the former draft, the Colleges must settle their own mode of election of the aforesaid members.—Her Majesty may dismiss members of the Council for notorious misbehaviour or unfitness; and in such case, or in vacancies caused by registration or death, a new election shall take place for the term left unfulfilled. The appointment of clerks and messengers is arranged as before, and the lord high treasurer, or the commissioners of her Majesty's treasury, are empowered to pay necessary expenses.

The clauses 10, 11, and 12 are also left unaltered.

In clause 13 the term, General Practitioner, is substituted for Licentiate, and September is substituted for January, as the month of registration. The precise source of diploma is now to be added to the register of the qualification, and a printed copy of the Register published by the Council, will be legal evidence of registration. The absence of the name will alone be proof of non-registration until the contrary appear.

14.—All may register as General Practitioners who are entitled to practise as Physicians, Surgeons, or Apothecaries, and who within twelve months after the passing of the act, shall be entitled to enroll, and shall enroll himself as a Fellow of the Royal College of General Practitioners, or who, (being twenty-two years of age) shall have been examined in England by the College of General Practitioners, or in Scotland and Ireland by the Colleges of Physicians and Surgeons, and have proved *five years* medical and surgical studies.

15.—To be a surgeon, there must be age twenty-six; examination undergone before a College of Surgeons—proof given of five years study; or else he must have been twelve years a General Practitioner, or twelve years a member of some College of Surgeons, and undergone examination as a Surgeon.

In clause 16 we have this alteration. General Practitioners of forty years of age, or those *now* legally practising as physician, surgeon, or apothecary, and who have done so for *twelve* years, shall, on examination by the College of Physicians, be allowed to register as physicians.

17.—A preliminary board of six surgeons and six physicians, chosen by the Colleges, is appointed, whose liceat is necessary to all candidates for all diplomas. The fee is not to exceed two pounds, which is to be divided between the two Colleges.

18.—Excepts present medical students from the operation of the law in such cases as the Council of Health may see fit.

19.—Physicians and surgeons must be members of the Colleges of the country in which they reside; and defaulters will be struck from the register, and pay a penalty, not more than five pounds, for each month of default.

20.—All registered General Practitioners in England must become Fellows of the Royal College of General Practitioners, and so in Ireland and Scotland with the Licentiates; and all defaulters shall be fined five pounds each month of default.

21.—The Council of Health are to control and equalize qualification and fees, but are not to make any change in any curriculum without fourteen days notice of the motion made known distinctly to each member of the Council.

22.—Universities are not, without special license of the Council of Health, to confer medical degrees on any one unless after matriculation, with *residence* of at least two years, together with a strict examination. This is not to give further license to the Universities than they now possess, but partially to limit the faculty with which, without *any* residence, they now often grant diplomas. By the next clause, therefore, they are empowered to grant a licentiateship in the Faculty of Medicine to any of their students after *five years* study. By 23, 24, and 25, the restriction on bye-laws and management of students registering are left as before; and the same facilities are afforded two corporations uniting for examinations.

27.—The Council of Health are allowed their old power of securing efficiency of *examinations in Universities* as in Colleges. Any member or secretary may attend any examination, and report to the Council, which may then cease to recognize a Faculty-board of Examiners.

28.—The Registered alone will be competent to public medical offices, and the Council of Health will be empowered to say what are public offices.

By 29, 30, and 31, the registered have the privileges proposed in the former measure, and reciprocal rights and practice are granted to practitioners of each part of the Empire.

32.—General Practitioners may charge for medicines and attendance, may fill all public medical offices, and are not to be interfered with by the exclusive privileges granted by any statute or charter.

33.—All legally practising on the day before the passing of the Bill may register according to their present titles in a supplemental register.

By clause 34, none but General Practitioners will be allowed in law to enforce charges for medical attendance; by 35 the old penalties on the non-registered in public offices are enforced; by 36, the College of General Practitioners have exactly the same power of repressing quackery as the Society of Apothecaries, all apothecaries in practice in 1815 being exempted, however, from the general operation.

38.—The unregistered assuming to be registered, or the registered to be on the registry what they are not, are made guilty of a misdemeanour, and will be punished by fine or imprisonment.

By 39, those guilty of fraud or felony may be struck off the register; and by 40, the privileges of Oxford and Cambridge are left intact.

This, then, is the new Bill about which so much anxiety is being felt. We must own that it strikes us as a wonderful improvement, and asks from us our best thanks for the good temper and kindly disposition which could induce Sir James Graham to sacrifice considerations to which human weakness is too susceptible, in his very earnest desire to meet the wishes of the Profession, and give it, finally, an acceptable measure of Medical Reform. But we must delay further comment till our next number, with the single remark that the only alterations we are likely to suggest, are so much mere matters of detail, that

if our medical brethren agree with us in our estimate of the present measure, there can be no reason why it should not take the shape of a law this very session.

———————— For a drudge disobedient;
And too fond of the right, to pursue the expedient.
In short, 'twas his fate, unemployed or in place, Sir,
To eat mutton cold and cut blocks with a razor.
GOLDSMITH.

MR. BERKELEY with a generous feeling that does him honour, has brought the injustice done to Mr. Dermott by the College of Surgeons before the notice of Parliament and the country. It is strong—perhaps *too* strong—language, which denounces the exclusion of that eminent anatomist from the Fellowship as a "disgusting outrage;" but, if we were allowed to call things by their names, it would be neither unjustified by fact nor unrequired by justice. For the fourth part of a century has Mr. Dermott devoted his industry and large ability to the service of surgical science in its highest walks. He has laboured harder at anatomy than probably any other man in the empire, and done as much as most people to facilitate its practical study. Clothed with the mantle of the ever-to-be-revered Brookes—whose favourite pupil and lecturing assistant he long was—he has crowded the army and navy with his pupils, and in every corner of the metropolis there are surgical practitioners in the zenith of fame and practice, who owe to his zealous teachings much of that skill which, saving the lives of others, makes happy and honoured their own. Notoriously, and to his own loss, is he one of the most honest, least intriguing, and frankest surgeons of the day. There never was a man with his heart more entirely or purely in his profession. The evil fortunes, moreover, that have fallen on so many private schools—those instruments of immense scientific good in their day—though but gently touching, have not wholly left uninjured the establishment over which he presides; and as voluntary teacherships in all professions have little kindred with Mammon, the maker of fortunes for others, is fain to be content, in these latter and evil days on which he has fallen, if with the maintenance of some little of his ancient hospitality he can with increased industry, still maintain the even tenor of his scientific way. With any superabundance of manly or generous feeling in the council, how irresistible would have been such a Surgeon's claim to whatever honour their Fellowship could confer? At such a moment—so interesting to the man of feeling—with such a man—so worthy with all his faults, if he have them, to the eye of Science—one would have fancied that the Council would but too gladly rush to do the handsome thing, that amid the unhappiness no doubt caused them by the invidious distribution of their newly coined honours, they would cheerfully have seized as one subject of solace the power it gave them to do honour—or, at least, attempt it—to a fellow surgeon of such long standing, and a surgical teacher of such eminent and successful ability. What, if in times when a fiercer competition existed among teachers, he was a formidable and not unsuccessful rival! The generous mind would find in that very fact, now that the bitterness of the struggle was past, additional spur to the boon that kindness prompted and justice asked. But the Council in their majority have no kindship to the just, the kindly, or the generous? Many and many of Mr. Dermott's pupils did they raise to the Fellowship; but the honour that noted by its gift *superior surgical science*, they carefully withheld from the professor. As Fulvia mangled the dead tongue which alive had so eloquently opposed her misdeeds, so this Council, as though woman-hearted, finding their rival placed in their power by Royal Charter, have approached a meanness unparalleled, only by the insolence of folly that has characterized too many of their recent doings and have gratified at his expense, and with an utter loss of decency and right, their agedpique and weak-minded vanity. Indeed, indeed, this *is* discreditable.

Of course the respectable Council (a body of gentlemen repudiating in the aggregate, the code of gentlemanly conduct they would respect individually)—of course this conscienceless junto will not scruple by fiction to gloss over the wrong they have committed in meanness. But, fortunately for Mr. Dermott, their act of injustice stands condemned by themselves. Out of their own mouths are they convicted. Sir B. Brodie, their president, has, in so many words, washed his hands of the shameful responsibility, and the Council themselves, in doing Mr. Dermott the distinction of deliberately and officially recognising him through so many years as a fit and competent teacher of anatomy and surgery to the numerous candidates for their diplomas, have defined in advance the wrongfulness and ill-spirit of their recent contumely.

Now this, were peat is not a *respectable* nor nice trait in the government of this unpopular body. They may depend upon it, ill off as they now are in every body's opinion—aye, and at *last* in their own—that this exposure—brief and hurried—of the indefensible act to which they have condescended, in a desire to injure and wound an old and respectable teacher, their own rival, will do them no good. The spirit which bears *ill*-official insolence from the proud spirited and noble, sickens into disgust or relieves itself with contempt when the wrong proceeds from the vulgar-minded and mean. The Council, bad enough from their general feeling, even if supporting their character as gentlemen, become an intolerable nuisance when they present themselves as tradesmen and *roturiers*. They should be far, very far, above the impelling motives of some village gossip in anger. We know no Government the world would detest more than a parish vestry clothed with the powers, and exercising the functions of a Venetian Council of Ten. No—this ill treatment of their rival teacher—an honest man—is not generous, is not seemly—is not consistent—is not gentlemanly—is not manly. It is *most* unjust. It is as the pugilists say—"*unfair and foul*,"—very *foul*.

"Quidquid agunt homines
————discursus, nostri farrago libelli."—Juvenal.
"Velut aegri somnia, vanae
Finguntur species."

WE have said that the *diuresis* which the trepidation of anticipated public speaking often gives rise to, may be sometimes remedied by a slight opiate taken preparatory to the occasion. We have known a single lozenge, containing one-sixteenth of a grain of morphia, completely relieve this distress. We are not going to dispute with De Quincey, the mystic ground of expressing or explaining the wonderful operation of opium upon the animal and intellectual system, but we cannot help thinking, that if we do not know a stray fact or two about it more than he knows, we at least can say a few things that are not to be found in his writings. Here let it be understood, that the furthest desire of our heart would be to undervalue the reputation of that great man—*clarum ac venerabile nomen!* We have an infinite regard for his various scholarship, his genius, and the melancholy memories of his singular lifetime. In his peculiar mind are to be found, oddly arrayed, the choicest gems of exotic and native literature. Profoundly versant and fluent in the languages of Greece and Rome, he has also drank, deeper than the surface, of the streams of learning, more oriental and cabalistic. At one moment, penning a witty Greek epigram upon the bag-wig of a pedagogue, at another, he will be criticising the critics themselves, or wantoning, in the plenteous fulness of a refined joy, amid the tragic mysteries of Euripides and Æschylus. Now toying with the liveliest of Fancy's children, in an atmosphere all smiles and sunshine, anon, he will utter—*suspiria de profundis*—the breathings of a heavy, half-broken heart. To-day, a kaleidoscope, representing in every colour and contour, the mirth of existence—to-morrow, a solitary picture, marked in its solemnity and sorrowing. As it were *in extremis*, he exhibits the opposites of nature in marvellous pleasantry or pain. He has taken more opium, *en masse*, and continuously, than perhaps any other human being. At one time, eight thousand drops of laudanum daily, were his customary potation! And this narcotic mass, which would hold any ordinary man's reason an eternal prisoner, merely served to intellectualise him! It elevated his faculties, and gave a plenitude and pleasantry to his mind. Only when asleep, was he tortured by it, in occasional painful dreams. There he felt, in an uncontrollable mastery, the passion, and the pang of intellect—

Dearly bought the hidden treasure
Finer feelings can bestow;
Chords that vibrate sweetest pleasure
Thrill the deepest notes of woe.

To him belongs the solitary merit of having given a complete account of the action of this drug both upon body and mind. He has delineated, with a master's skill, and a martyr's suffering, "the pleasures and the pains of opium"—

As when some great painter dips
His pencil in the gloom of earthquake and eclipse.

He has felt its effects in all their phases, both sorrowful and mirthful, and has not only himself looked "on this picture, and on that," but has so held the "mirror up to nature," that even the learned in physic have not hesitated to paint from his original. He has dictated his personal truths to schoolmen, and to this day, the law of his self-experience is paramount in the profession. A veneration of antiquity and of great names, has been an occasional means of introducing a heterodox opinion and doctrine into the Materia Medica—at this very time, our established drug-legends and recipes, exhibit, here and there, the tracery of alchemysts, necromancers, and a meddling, polluted priesthood. To us the apothegm, *de mortuis nil nisi bonum*, seems to be especially sacred, and we receive, and quietly revere the exquisite nonsense of old, out of respect for the venerable medium through which it is introduced to us. It is thus that classical literature maintains its precedence, and that the facts which it contains, though in their essence exploded, still command the patronage of the scholar. But De Quincey's is the only modern instance with which we are acquainted, of a non-medical writer submitting, upon a medical subject, an opinion which the whole profession has acknowledged as orthodox testimony. And more especially is the fact remarkable, inasmuch as his theory of the *modus operandi* of opium, is in some sort opposed to that of the legitimate *pharmaceutist*. "For upon all

that has been hitherto written on the subject of opium, whether by travellers in Turkey (who may plead their privilege of lying as an old immemorial right) or by professors of medicine writing *ex cathedra*, I have but one emphatic criticism to pronounce—Lies! lies! lies!" That is just what he says, and a pretty tolerably cool specimen of contradiction we call it. There is an old story of two countrymen who waged themselves, each against other, to squeak like a pig. One of them, less confident than his competitor in his powers of vocal mimicry, covertly carried a sucking-pig under his frock. Having to lead in the contest, he slily pinched the animal, which thereupon uttered sounds that were declared by the judges to be exceedingly pig-like. But the other man, single-handed, or rather single-mouthed, squeaked in a manner so much more natural, to the taste of the adjudicators, that they unanimously declared him the victor. One and all agreed that he had squeaked more like a pig than a pig itself had done. So much for the competency of human judgment. Now, without desiring for a moment to draw any comparison between very opposite parties, we cannot help thinking that to make De Quincey, in the face of the whole profession, an exclusive authority upon the subject of the action of opium, great though his individual experience has been upon it, is, after a certain fashion, to place the contending parties in the humorous relation in which those stood who are named in the above joke. Though we are ready to confess that De Quincey has told us much about opium that we did not know before, and that we are indebted to him for many standard facts concerning it, yet must we also aver that he has often been too imperative and prejudiced in his statements. He has drawn a general inference from his single experience, and has made a solitary example the source of an universal law. Without any allowance for variations in intellect, temperament, strength of constitution, idiosyncrasy, he has deduced that such and such are the effects of opium, take it who will. Upon himself—a scholar and a genius, each of rare excellence—it produced certain intellectualizing effects—it made the senses more acute, the intelligence more comprehensive and brilliant, and seemed to elevate the whole man above the earthliness of his common nature. Even to his dreams it imparted a gaiety or a gravity, yet still of a perfectly *ideal caste*. The beauty was all expansive, light, lovely, and mental—an elastic amplitude, a rich and varigated drapery of thought—a diffusion, supreme and simple, of the choicest components of beatitude, floating in a delicious intermixture, and imparting joy chiefly by being called and collected at the inspired will of the intoxicated dreamer. The agony was of another dye—it borrowed the hues of Acheron, and the chorus of the Eumenides was its music. It was an Iliad of woes—a tribe of tortures greater even than those which visited the couch of Orestes. No happiness so exalted, no misery so profound: pleasure did its best, and pain its worst, in their harlequinade through the drugged brain of this martyred man. Had De Quincey administered to others as many doses of opium as he has taken himself, he would have learnt from each fresh experience, that his own instance is no index of the common operation of the medicine. He would see it send one man quietly to sleep with no dreams to disturb it—an easy repose like that of infancy, calm in the complete rest of all thought and sense. He would see another troubled with the agonies which himself endured—a disturbed imagination, horrifying a conscience innocent of the ideal iniquities preferred against it. A third would be kept awake, all smiles and laughter, redolent of philanthropy and universal love, and free to unbosom the dearest secrets of his heart to the first candidate for his acquaintance. Perhaps as liberal of his money as of his mind, and ready to go surety even for a stranger. A fourth would be the opposite of these things—sullen, morose, and suspicious—ill at ease with himself and all around him. He would see it produce pain in one case, and remove it in another, and indeed perform such various contrarieties, as could only be accounted for by supposing that the habit of the individual in some measure determined the action of the drug. And this knowledge is that, which alone is required to render De Quincey correctly conversant with the *modus operandi* of opium. Nevertheless, labouring as he has been under the difficulties which beset a course of practical inquiries, it is wonderful that the fidelity of his details should be so little liable to exception.

We have made this digression, because we felt that we could not touch upon a ground rendered sacred by the tread of genius, without pausing at the commencement with an episode to its praise. We look upon the "Confessions of an English Opium Eater" as one of the most masterly productions that ever issued from human brain—and great as it is both in the field of literature and physic, we have deemed the time not ill-employed which has been devoted to a brief, but we believe an original, analysis of itself and its distinguished author.

It would not consist with our purpose that we should in this place enter into a lengthened consideration of the physiological action of opium; we may some day do so, but our present object is simply to offer a prelude to certain cases we have promised to give, illustrative of some curious and rather 'unlucky' effects produced by opium taken preparatory to public speaking. These, however, must appear in our next article. But we cannot in the present instance withhold the record of an extraordinary delusion occasioned by an opiate, in the person of a gentleman with whom we have the pleasure of being most intimately acquainted. To relieve a laryngeal cough with which he was troubled, he sucked one night, prior to going to bed, a few morphia lozenges, he could not say exactly how many. He remembered to have retired and undressed himself as usual, and to have attended to all the particulars of the toilette, in which he was especially neat, for though a plain man, he had all the vanity of a handsome one. He placed his night-lamp on the mantel, and got into bed. He lay looking, as was his wont, at the taper, until it became slowly surrounded by a halo of thinnest mist, which gradually filled the whole room. At the same time he felt himself growing by degrees lighter, until at last he fancied himself to float upon the very wings of ether. He could move in any direction, and variously tried the action of his limbs, but every effort gave him a further and more fertile idea of his imponderosity. Shortly, the notion possessed him that his head was off. Though not painful in itself, the idea led to others of a most distressing kind. He wondered what he should do without it, what people would say and do to him, and whether his life were not at risk in the change. Strangest of all, though perfectly intelligent of every surrounding object, seeing the various articles in his room—hearing the church-clock strike—moving his limbs to and fro, and thinking of all these things—it never occurred to him to feel if his head were on, or to reflect that, without a head he should be in no wise sensible of its loss. The single delirium seemed to be imperative of every faculty and feeling that could lead to its correction. All this while the man was perfectly awake to everything save his delusion—it spell bound him. After lasting for upwards of two hours, during which time he carefully numbered the chimes, sleep hid the terror from his eyes, and it was at his breakfast-table the next morning that we heard him relate this strange incident.

Mr. Wakley brought forward his motion mentioned in the article we have elsewhere given from the *Chronicle*, last night, Thursday. The Government, with some difficulty, mustered a house for him, and after indulging him with his say, quietly had it counted out, Sir James Graham passing by the Hon. Member's speech as one not requiring any reply.

FELLOWSHIP OF THE COLLEGE.

To the Editor of the Medical Times.

SIR,—I herewith send you a copy of a protest I yesterday forwarded to the President and Council of the Royal College of Surgeons of England, from the metropolitan districts of Kensington, Brompton, and Chelsea, the receipt of which has been duly acknowledged by their Secretary, Mr. E. Balfour. I shall be obliged by your early insertion of the same in your truly valuable journal.

I am, Sir, yours most faithfully,
C. H. BARNES.

Belle Vue House, Notting Hill, May 3, 1844.

TO THE PRESIDENT AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

We, the undersigned, being Members of the Royal College of Surgeons of England, residing in the metropolitan districts of Chelsea, Kensington, and Brompton, feel it due to ourselves individually and collectively, to record our earnest and indignant *protest* against the recent proceedings of the Council in respect to the unfair election to the Fellowship.

We strongly and solemnly protest against the arbitrary election of a few gentlemen above those of their brethren who were previously their equals in professional rank, *senior* to many of them in their standing as Members of the College, and not *inferior* to any of them in scientific and practical knowledge and attainments.

We also consider the invitation to the mass of the members to undergo another examination, in order to obtain the rank of fellow, which has thus been most unjustly and unfairly conceded to a select few, to be an affront to the respectable Members of the College, under which, if we remained silent, we might be considered to have merited.

We cannot forbear expressing our astonishment at the degrading answer which has been very recently returned to the Committee of the National Association, by the Council of the College, and to record our regret, that the recent attempt at a reconciliation recommended by the Committee, and adopted by them at the express wish of the Home Secretary, Sir James Graham, has thus been rendered *futile* by the most insulting answer of the Council to the great mass of the members.

THE AMENDED BILL.

(To the Editor of the Medical Times.)

SIR,—I address you with no ordinary feelings of concern at this crisis, when the destiny of the profession hangs upon a thread, and evils are likely to be entailed by the next reading of the Bill, which will be with great difficulty removed hereafter; perhaps never.

This Bill, with all its most glaring sins about it, is ordered to be recommitted on the 9th of June, which recommittal may probably be the final stage of the Bill, because the Bill, as it now stands, or with any "amendments" which may then be introduced, may be agreed to the same evening.

Sir James Graham, in the commencement of his speech, said, "there are differences existing between the *general practitioners* of England, and the *great body of the College of Surgeons*, which it is his earnest desire to adjust!" Now the "differences" that do exist, and they are great, exist between the *Members of the College of Surgeons*, most of whom are general practitioners, on one hand, and the self-elect Council of the College of Surgeons on the other.

He says again, "if the general practitioners, a body so numerous and powerful, were to have the complete constituent power in returning the representative body, the governing body of the College of Surgeons would be nothing but a reflex of the general practitioners," and that it would be the means of "transferring the College of Surgeons to Apothecaries' Hall." Now the present Apothecaries' Company, in spite of their individual and collective merits, are a mercantile, wholesale, and retail drug company; the College of Surgeons are not, and cannot be made so. If the Council of the College of Surgeons were thrown open to the franchise, and the examination-board to fair competition of talent, it does not follow that they must examine in Medicine, and if they did, they would only be analogous to the Faculty of Medicine and Surgery in Paris—the highest medical tribunal as a test of proficiency in Europe.

Sir James Graham states, that he fears it will prove "vain to attempt to reconcile the differences between the two bodies"—vain, indeed, so long as he, having the means at his command, does not have recourse to it—the *franchise*—which may be effected either by throwing open the Council of the College to its members, or by incorporating the medical practitioner in one faculty of medicine and surgery upon the elective system, and in such a manner that they shall not be subservient to the Colleges of Physicians and Surgeons.

Sir James Graham states, that the members of the Council of the new incorporation, are to have the double qualification, *i. e.*, Diploma of the College, and License of Apothecaries' Company, so that if Surgeons enrol themselves, it is a question if they can be legally accepted; or, if so enrolled, they would only belong to the corporation nominally, without enjoying its rights, privileges, and honours. If they allow apothecaries, not having passed any surgical examination whatever, to register under the Bill, as Licentiates of Medicine and Surgery, surely those Surgeons who have not been admitted into the Fellowship, and who have already incorporated themselves (as I have done), or desire to incorporate themselves, ought to be admitted to all the rights and privileges of the New Incorporation. If this be not the case, those surgeons not included in the Fellowship, will be completely and doubly outlawed.

Sir James Graham states, that "it has been urged by persons, who are entitled to the greatest respect, that the elective principle in the Council of Health should be abandoned, and the power of nomination vested solely in the Crown, under certain restrictions!!!"

So far from this being true, Sir James Graham may rest assured, (and time will prove it) that nothing less will satisfy the profession than allowing the College Council to be chosen by the members, and an infusion at least, of the boards so constituted into the "Council of Health."

As to the other proposed amendments; the incorporation of General Practitioners will prove a failure in its present form subservient to the other two colleges. Teachers are to be placed by the Bill in perpetual collision with their pupils, by the registration being carried on in the several schools, instead of at the colleges, and a wide field opened for fraud or connivance. "Pure surgeons" who are not fellows, apothecaries, and those with a double qualification are to be huddled together in the registration, whilst the privileges and honours of the body as hereafter to be incorporated are to be specifically withheld from the former. The medical profession, as touching education, based upon the certificate system, is only to be opened by a *very heavy* golden key, and private patronage is to be more rampant than ever.

I say then to the members of the profession, *teach the principles of Medical Reform by documents and interviews*, by pouring PETITIONS into the Home Office and House of Commons, as numerous as possible, but short and perspicuous, in order to convince Sir James Graham that nothing short of the *elective system* comprehending *a full and fair enfranchisement will satisfy the profession.* This should be done preparatory to the 9th of June; but there must be no pause, no hesitation, no wavering, all the profession must act with energy and unity of purpose as one man! Wakley could, if he had a better character, render much assistance in such a final struggle. You have awakened the profession to their true position; cautioned and protected them against false friends, and at last have forced that honourable person to act and make at least the appearance of an attempt to do something. *If any permanent good is effected at last by him, it will be in a great measure attributable to your strenuous and untiring efforts.* The castigations you have judiciously administered to the idlers and evil doers have not and could not be without effect.

It is my intention, if necessary, to petition, to be heard by council against the Bill and Charter at the Bar of the House of Lords. Will any of the profession form common cause, and unite with me in this effort?

Your obedient Servant,
G. D. DERMOTT.

Charlotte Street School of Medicine, Bloomsbury, May 11th.

THE GIESSEN DIPLOMA.

To the Editor of the "Medical Times."

SIR,—In proportion to the respectability of any publication, so are the public safe from being made the subjects of false attacks. I was, therefore, surprised to find the pages of the MEDICAL TIMES devoted to the publication of a correspondence concerning the Giessen Diploma, between a Dr. John Bond and a Mr. Wilson, both of them disguised under assumed names, in which they have asserted the most gross falsehoods, and mentioned the name of Dr. Roberts, a highly respectable member of the Profession, in such a way as to induce persons to believe that this gentleman has not had the advantage of a regular medical education.

I am induced by a sense of justice to reply to these letters, though an impartial investigation of facts would prove that neither of your correspondents is worthy of confidence and notice. Mr. Wilson, though totally unknown, styles himself a friend of Dr. R's, and to show the nature of his friendship, states in one of his letters that, "Dr. R., must not expect to be regarded in the same light, or treated on the same footing as those who have undergone the usual medical education." The injustice of this remark will be evident, when I assure you, that Dr. Roberts is a legally qualified General Practitioner, received in London in 1836. His medical education commenced in 1826,—at which time he was articled to a surgeon in extensive practice; at the expiration of his articles, viz., in 1831—he entered as a matriculated student at King's College, London, where he studied medicine during five years. Of these facts your correspondents could not have been ignorant, for the proofs of which, his medical education, his success and extensive practice are of public notoriety in Paris. Indeed all this commotion on the part of the British M.D's practising in Paris with reference to the degree of M.D. is ridiculous. In the present day the education of the General Practitioner of England is equal, if not superior to that of the Physician or pure Surgeon, and natural talent, study, and practical knowledge, not rank nor title—are the only real distinctions, for genius knows no law.

JUSTITIA.

Paris, April 16th, 1845.

[We have of course been favoured with the writer's name. This correspondence must here close, with this single remark from ourselves, that unequal titles with *equal* education is the bane of British Medicine, and the source of more dissension and ill feeling, than almost any other grievances we have to complain of. The case of Dr. Roberts is a useful exemplification of the fact.—ED.]

THE MORNING CHRONICLE AND THE MEDICAL REPRESENTATIVE.

As might be expected, the Government project to create a new faculty of medicine in England is exciting no small sensation among the disciples of Hippocrates. Speculation naturally busies itself with the questions, What ground will the new corporation occupy? What importance will it attain? What are to be its privileges and powers, and what its ultimate results? On all these interesting points we can do little more than guess, until her Majesty's printer shall have favoured us with the *third* edition, revised and corrected, of the Home Secretary's *very successful* bill. One thing however, is clear. The Committee of the National Association will fail in policy as well as in duty, if they consent to accept any charter which may place them in an equivocal position, in reference to any large body of their constituents. The new college must start well. Standing before the public, untried, bran new—a *parvenu* corporation in hostile rivalry with the ancient colleges brightened with the fame which a hundred noble names have thrown around them—the Faculty of general practitioners, to maintain a fitting position of usefulness and respectability, will want every fair aid the state can give them. While nothing should be introduced in their charter which may detach

from them the sympathies of one member of the body of general practitioners (whose unanimous support is almost a primary necessity), it should be so framed also that the public may see nothing in it whence to infer against them imputations of inferiority or unimportance. The field of English medical practice being thrown open to the *alumni* of all the Irish and Scotch licensing bodies, the new faculty will flourish or fall according to its repute. As the public will *rate*, so will medical students *seek* its diplomas; and if it cannot start well, free, unfettered, and without the shadow of a stigma on its science or social standing, a thousand times better would it be to let the Minister fulfil his threat of abandoning his work in despair, and maintain their voluntary combination, awaiting patiently the turn of events.

The association should be the more vigilant and decided on this point, because it is not unlikely that Sir James Graham will spare nothing to save the College of Surgeons from the pecuniary losses which a really effective Faculty of general practitioners would be certain to inflict. Having himself involved them in much of their present unpopularity, he may be supposed somewhat anxious not to be the person to deal them too severe a measure of punishment. But the association can be influenced by no such feeling. Their business is to see that they suffer for nobody's faults but their own. The council of the surgical college have deliberately taken their stand on the ground of *pure* surgery, no matter at what cost to others: they must now be kept to it, no matter at what cost to themselves.

We see, by the way, that Mr. Wakley's motion for an inquiry into the affairs of this devoted corporation, has not, after all, as those learned in physic had prognosticated, given up the ghost. Despite the series of "accidents and offences," pitiable to chronicle, which it has gone through, it is to reappear this evening in guise more formidable than ever. Taking a lesson from the beggar of Gil Blas, whose appeals to pity were supported, as everybody knows, by an undeniable reference to a neighbouring musket, Mr. Wakley distinctly warns the House than he has ready loaded and primed for it a second speech, if it refuse him the prayer of the first. He is quite content to accept gratefully "the inquiry," if granted, but if refused—what then? Why, in the words of the order paper, "*Should* that resolution *be* negatived," he is "then to move the following:—That in any charter which the Crown may be advised to grant for the incorporation of the general practitioners, those gentlemen are fully entitled to enjoy an equality of professional station with the newly-created fellows; that a deep and lasting injury would be inflicted on many thousands of scientific men, if a College of General Practitioners were founded as an institution inferior to the College of Surgeons."

Now we will do the propounder of these motions the justice of owning that we can conceive circumstances in which they would do anything but waste time that could be better employed. But they are not the circumstances we have at this moment to deal with. The true time for enquiry about the College Charter was when it was granted; that is to say, much about the the time that Mr. Wakley's brother received from a Tory Government the lucrative position of official assignee of bankruptcy. The Charter was not published a week before the members, in whose name it was surreptitiously asked and conceded, condemned it as unconstitutional and unjust; and if at that period some member of Parliament had brought the matter before the House, it is not to be doubted that he would have saved the surgeons of this country much of the vexation and injury they have since suffered, and shielded the prerogative from doing *de facto*, what it cannot do *de jure*—wrong to the subject. *Now* the inquiry comes too late. The mischief is done; the injustice is known and acknowledged; and if reparation at the present late hour of the day is not to be made without Parliamentary inquiry, it is easy to see that it will never be made at all.

Nor is the alternative less ill-timed with which Mr. Wakley threatens the House in the event of a defeat—viz., a Parliamentary discussion on the new College. If the one be too late for any useful, the other is too early for any orderly purpose. The erection of a new national college is to form an important part of the amended bill; and it is scarcely fair in any isolated member to force the House, by a chance motion, *to be* discussed *in the event* of another being negatived, to decide, in advance, questions that are to be discussed in due course, on a fixed day, and while legislating on the Ministerial measure that actually contains them. The honourable member for Finsbury wishes, no doubt, to make up for lost time, but in this case he has not been fortunate in his selection of the occasion. On reconsideration, he will see, we are sure, that in his natural anxiety to have, however late, some share in the Parliamentary settlement of medical reform, he has been hurried into steps that endanger the cause be has at heart. He places, we fear, too much import on the worse than frigid reception that greeted him at the great meeting of the National Association of general practitioners held a few days back. Temporary alienations of popular confidence must happen at times to every public man, and the way to recover position in such cases, is to keep the even tenor of our way, and bide our time. Ill-placed activity and ill-timed restlessness only augment the suspicion they are used to ward off. The medical profession, like the rest of the world, if tempted to attribute the self description of "Comus" to their public men, will apply it if not one whit the less because augmented bustle covers what they may think attempts to mislead:—

"I, under fair pretence of friendly ends,
And well placed words of glozing courtesy,
Baited with reasons not unplausible,
Wind me into the easy hearted men,
And hug them into snares. When once her eye
Hath met the virtue of this magic dust,
I shall appear some harmless villager,
Whom thrift keeps up about his country gear."

GOSSIP AND NEWS OF THE WEEK.

Several physicians in Newcastle on Tyne have petitioned the House of Commons to refuse passing the Bill for newly Chartering the College of Physicians until the Charter be submitted to the Profession. They protest against the illiberal limitations contemplated for the Fellowships.

Zoological Gardens, Regent's Park.—It will be interesting to the lovers of natural history to learn that an American sea eagle (Haliœtus leucocephalus) is now engaged in the process of incubation, the male occasionally taking her place on the nest, and showing the utmost attention to his mate. A specimen of that extraordinary animal the Australian ant-eater (Echidna histrix), the first that has been seen alive in Europe, has just been added to the collection.

Gentlemen admitted members of the Apothecaries Hall, on the 24th of April, 1845:—Robert Manners Mann, Thomas Stevens Barringer, H. Alexander Nowell, and Thomas Harrison.

Gentlemen admitted members of the Apothecaries Hall, May 1st, 1845:—William Byers Sealy, John Gabb, William Withall James, Robert Sage Ellis, George Turner, George Williams.

Gentlemen admitted Members of the Royal College of Surgeons on Friday, April 25, 1845:—R. Roper, H. Birkett, C. F. Blackman, R. Horton, J. Ash, M. Walling, S. S. Dyer, A. Fergus, W. Cooke, W. H. Freeman, E. J. Wilson.

Middlesex Hospital.—The distribution of prizes to the successful candidates at the School of Medicine attached to this hospital took place in the early part of last month. In medicine the first prize was awarded to Mr. Tucker, the second to Mr. G. Foote; in surgery the prize was gained by Mr. G. Foote, the certificate of honour by Mr. Tucker; in anatomy, the prize was gained by Mr. G. Foote, the certificate of honour by Mr. Augustus Grant; in physiology, the prize was awarded to Mr. Grant, the certificate of honour to Mr. Bousfield; in practical anatomy the first certificate was awarded to Mr. A. Grant, the second to Mr. A. D. Home; in materia medica the first certificate, Mr. Johnson, second, Mr. Pates; in chemistry the prize was gained by Mr. Beyers, the certificate by Mr. Johnson; in midwifery the prize was gained by Mr. G. Foote; in forensic medicine the prize was gained by Mr. G. Foote, the certificate of honour by Mr. Tucker; and in botany the prize was awarded to Mr. Bousfield, the certificate to Mr. Spicer. In addition to these, the Rev. Dr. Laing's theological prize was gained by Mr. Frampton, and Mr. Tooke's first prize of £15 for general proficiency by Mr. G. Foote; the second of £10 by Mr. Tucker. The prizemen were successively complimented on their exertions by their respective lecturers.

At a late meeting of the Royal Society a paper was read, entitled, "Description of a self-registering thermometer," by Mr. Mansfield Harrison. The instrument is composed of two parallel bars, the one of iron, the other of copper, united at their lower ends, and registering their differences of expansion by heat, by means of a series of multiplying levers, carring a pencil which is made to press on paper wound round a cylinder moved by clock work.

Four Brahmins of high caste have arrived in this country for the purpose of studying medicine at University College. They are intended to take degrees, with the view of placing them on the same footing with the faculty of India, and at the same time enabling them, as natives, to spread in the interior the knowledge they have acquired in our institutions. Two of these students are sent over by Sir Henry Hardinge, at the expense of the East Indian Government, one by public subscription amongst the citizens of Calcutta, and the fourth by Dwarkanauth Tagore, an Eastern philanthropist.

Mr. Gill, of Syston, near Leicester, thus addresses us, offering Sir James Graham a significant hint on the wisdom of empirical liberty:—"Having been a reader of the *Medical Times* for the last two years, and looking upon you as the guardian of the medical profession generally, I am induced to lay my case before you, and to solicit your opinion thereon. A person who has passed neither Hall or College has commenced practice in my immediate neighbourhood, by contracting with certain sick clubs, to find leeches, medicines, and attendance for two shillings per member per annum! Have I any remedy, and if so, what is it?" There is no remedy but an appeal to the Apothecaries' Society, who, in the present unsettled state of medical politics, will not probably prosecute, and thus a worthy practitioner is injured, and the lives of the foolish club people kept in jeopardy. The present bill of Sir James Graham, we fear, will not meet cases like this.

Charing-Cross Hospital.—*Medical School.*—The annual distribution of prizes to the pupils and students most distinguished for their acquirements in the various branches of medical study during the past session, took place on Thursday, May 1, 1845, the Rev. G. H. Bowers, B.D., in the Chair. *Winter Session*, 1844-5.—Exhibition of £15 per Annum: Mr. Joseph Fayrer, Bermuda. Medicine—1st: Mr. Philip Harry Harper, Walsall, Staffs. 2nd Equal: Messrs. Thomas Mc Greal, West Port, Mayo, and Henry Watts, London. Surgery—Senior Class—1st: Mr. Frederick Nicolle, Jersey. 2nd Equal: Messrs. P. H. Harper, and T. Mc Greal. Junior Class: Mr. Joseph Fayrer. Midwifery—Senior Class—1st: Mr. Frederick Nicolle. 2nd: Mr. Thos. A. O'Flaherty, Tralee, Ireland. Junior Class: Mr. Henry Watts. Physiology: Mr. Joseph Fayrer. Practical Anatomy. Senior Class—Equal: Mr. Thomas Mc Greal, Mr. Philip Harry Harper. Junior Class—1st: Mr. Henry Lambden, Horncastle, Lincolnshire. 2nd: Mr. Joseph Fayrer. Chemistry: Mr. Joseph Holmes Buxton, Bishop Auckland. Materia Medica: Mr. Joseph Fayrer. Diligence and Good Conduct: Messrs. Harper, Lambden, Watts, and Fayrer.

Society for Relief of Widows and Orphans of Medical Men in London and its Vicinity.—The dinner of this society, on Monday, is likely to be very numerously attended, and those who intend to be present are recommended to give early notice. This will be the first dinner of the society since the election of Sir Charles Clarke as President. Although, of course, the managing

committee will have taken due precautions in the arrangement of the toasts, &c., to exclude, as much as possible, all obvious causes of irritation, yet, at this time, when opinions are so much divided, it will depend mainly on the good taste and good feeling of individuals, to preserve that temperate and harmonious tone which befits a social meeting, where men of various opinions are assembled to promote the laudable objects of the institution. No doubt, however, need, we hope, be entertained on this head.

Gentlemen admitted members of the Royal College of Surgeons on Friday, May 9th, 1845:—J. H. Wilkinson, F. J. Kent, W. B. Hay, R. Butler, S. B. Shaw, J. Nihill, F. Farr, T. Mc Cheane, J. Rogers.

Gentlemen admitted members of the Royal College of Surgeons on Tuesday, May 13th, 1845:—J. Pointon, J. A. Cooksey, H. Pelau, P. H. Harper, H. Mathias, G. Hazel, T. D. W. Wheaton.

Gentlemen admitted as Licentiates at the Apothecaries' Hall, May 8th:—John Alfred Graham, William Burrows Buller, John Hunt, Charles Bedingfield Wood, James Northcote Vinen, Valentine Hutchinson, John Kenrick Lewis, John Hayball Paul, Charles Sturges Jones, Edward Schaw Protheroe, John William Mountjoy, William Thornicroft Hardern.

Tumour in the right Fallopian Tube, Occurring in the Pregnant State.—Dr. Waddy in the *Provincial Medical Journal*, relates the case of a woman, to whom he was called, and found her presenting some symptoms indicative of pregnancy, together with pain in the right inguinal region. The application of leeches, and the exhibition of an aperient relieved her at the time, and he did not see her again for three months, when he found her suffering from pain in the same situation, in the region of the round ligament of the uterus. She was pale, sick, fainty, and suffered from symptoms strongly resembling those arising from strangulated hernia, or the lesion of some important organ. He ordered fomentations and leeches, and repeated aperient medicine, which again afforded relief. A few days afterwards he was again sent for, and found her in bed; she complained of the pain in the groin as much increased in severity. Leeches, fomentations, and aperients were directed as before and he again saw her in the course of two hours. The pain was then constant, and severe to the most extreme degree, and strongly uterine in its character. The face was pale, countenance collapsed, general surface cold and bedewed with perspiration; the mind anxious. On examination per vaginam, the uterus was larger than usual, the vagina plentifully supplied with mucus, as in early labour, but no motion of the child on ballottement could be discovered. The os uteri was closed. During the course of the day, the pains became, if possible, increased in severity, and without the slightest intermission; the countenance pale and exsanguineous; nausea; frequent vomiting; pulse about 140, small, wiry, and feeble, and there was every evidence of some important lesion of an internal organ. Leeches and large doses of calomel and opium were ordered, which mitigated the pain. The diagnosis was, rupture of the Fallopian tube of the right side, from extra-uterine pregnancy. Peritonitis ensued, and Dr. Evans, and afterwards Dr. Ingleby were called in consultation. The repeated application of leeches proved of some service; calomel and ipecacuana were exhibited, a blister applied over the abdomen, the denuded surface being dressed with mercurial ointment. Ptyalism having been induced, the pain and other symptoms were mitigated in severity, consequently some hopes were entertained of recovery; collapse however occurred again and again, and the patient ultimately sunk.

After death the abdomen was examined. The intestines were apparently healthy, but much distended by flatus; there was no effusion into the peritoneum. The uterus was gravid, containing a fœtus of the fifth month. There was a large tumour, of the size of a child's head, occupying the situation of the right Fallopian tube; it consisted of several cysts, filled with blood; some of them had burst already, and there was a small quantity of bloody purulent matter beneath the tumour, which strongly resembled the placenta in structure; in Dr. Waddy's opinion the case was originally one of twins. One child had found its way into the uterus, the other had been arrested in its course, and becoming blasted, the fœtal membranes had undergone the alteration just described. It is now generally admitted, Dr. Waddy observes, that uterine hydatids owe their origin to pregnancy. In this case the cells, instead of containing a watery fluid, were filled with blood. The sacs bursting from time to time had occasioned rents in the Fallopian tube and its investing membranes, which produced the deadly faintings, nausea, vomiting, hiccough, and general symptoms of abdominal lesion. The pressure of the diseased mass upon the cæcum and ileo-colic valve, had all the effect of stricture, and prevented a free evacuation of the fæces. Had any means of correct diagnosis been established, an operation might have been probably successful, as the whole mass was unattached, excepting by the Fallopian tube, to the uterus. The difficulty of diagnosis was much increased by the presence of the fœtus in utero, by the excessive tympanitis and abdominal tenderness, which repelled the slightest touch, and almost precluded any manual investigation.—The case is a very instructive one on many accounts. One opinion given was, that the mischief arose, in all probability, from stricture or other mechanical impediment existing at or near the cæcum, and to this judgment the patient's friends were most inclined; and there were symptoms which appeared to favour this opinion. The stoppage of the bowels, the difficulty in forcing a large injection with the syringe and the colon tube, the dulness of sound of the cæcal region, indigestion, aphtha, eructations, &c., all seemed to point out the cæcum or intestinal tube as the injured part. Another diagnosis, to which Dr. Ingleby strongly inclined, was, that the symptoms were those of peritoneal inflammation, the cause of which he thought not sufficiently made out. The question occurs, could any other examination or inquiry have discovered anything more? The extraordinary distention and pain of the abdomen were such as to preclude the use of the stethoscope. No examination could have been borne that would have discovered the fœtal sounds; and had they been discovered, the difficulty would not then have been met, for the question would still have existed,—Is the fœtus in the Fallopian tube, in the cavity of the abdomen, or in the uterus. In future cases of similar character, strict attention to the primary symptoms, Dr. Waddy says, will be found of the utmost service in diagnosis. It was this attention which led him to the approximative diagnosis he gave, which was founded on the following considerations:—1. The general symptoms of pregnancy, absence of menstruation, and the condition of the breasts. 2. The primary situation of the pain, in the region of the inguinal canal. 3. The uterine character of the pain. 4. The general symptoms attending rupture of an important organ, and 5. He explained the constipation by the pressure either of the tubal pregnancy upon the ileo-cæcal apparatus, or by its escape into the cavity of the abdomen, and entangling those parts either by mechanical interference or inflammatory obstruction.

Excessive Loss of Blood.—The symptoms which arise from excessive loss of blood, and constitute the stage of collapse, are as follow:—1. Vertigo, syncope, coma, dimness of vision, dilated pupils, præcordial distress, weakness, tinnitus aurium, sense of darkness.—2. Convulsions, jactitation, strabismus.—3. Feeble action of the heart; pulse slow, quick, weak, imperceptible; face and general surface, pale, cool; extremities cold; lips white features contracted.—4. Respiration suspirious, slow, irregular, imperceptible.—5. Nausea, vomiting, eructation, and 6. cold sweats.

We are authorized to state that Mr. Healey, the barrister, is preparing for the press an elaborate work "on the Laws of the Medical Profession." The time of its publication will naturally, depend on the fate of the new ministerial measure.

A SELECT PRACTICAL FORMULARY.

TRANSLATED FROM THE FRENCH OF M. FOY, PRINCIPAL PHARMACIEN OF THE HOSPITAL SAINT LOUIS, AT PARIS.

(Continued from page 72.)

Syrup of the Ferruginous Citrate of Potash: a syrup, containing one ounce of the liquid citrate of iron and potash to fifteen ounces of simple syrup. Mode of exhibition—half an ounce to an ounce in a little water, as tonic and astringent, in chlorosis, leucorrhea, &c.

——— of Codeine: a syrup, containing twenty-four grains of crystallized codeine in the pound. Mode of exhibition—by coffee-spoonsful evening and morning, for children labouring under hooping-cough. It is also successfully employed in severe nervous irritation of the stomach.

——— of Colchicum (Edinburgh formulary): a syrup prepared with one part of fresh colchicum roots, sixteen parts of vinegar, and twenty-six parts of sugar. Dose—from one to twelve drachms in the course of the day.

——— of Spilanthus Oleraceus (Beral): one pound of simple syrup, two ounces of tincture of spilanthus oleraceus, mixed together in a silver skillet, and all the alcohol evaporated; after which it is to be withdrawn from the fire, and allowed to cool. Mode of exhibition—half an ounce to an ounce in an appropriate menstruum, as tonic and anti-scorbutic.

——— of Cubebine (Labelonge, pharmacien): a simple syrup, containing in the pound forty-five grammes of the hydroalcoholic extract of cubebs, rubbed with twelve drachms of gum mucilage, mixed with peppermint-water. Mode of exhibition—by coffee-spoonsful in water, in gonorrheal affections.

——— of Cuisinier; a syrup prepared with sarsaparilla, borage, and white rose flowers, senna, aniseed, honey, and sugar. Mode of exhibition—two to three tea-spoonsful evening and morning, as anti-syphilitic.

——— Cyanic (Magendie): simple syrup, containing one drachm of medicinal hydrocyanic acid in the pound. Mode of exhibition—half a drachm to two drachms in a pectoral potion.

——— of Dessessart: a syrup, composed of grey ipecacuana, senna, white wine, red poppy-flowers, tops of wild thyme, sulphate of magnesia, sugar, and orange flower water. This syrup is employed for the relief of cough in children, from one to two ounces being given in the course of the day.

——— of Emetine (Magendie): simple syrup, containing one grain of emetine in the four ounces. Mode of exhibition—two to four drachms in an appropriate menstruum. It possesses the same properties as ipecacuana.

——— of Diacodium: a syrup, containing four drachms of the alcoholic extract of poppies to the pound. Mode of exhibition—half an ounce to an ounce, in potions, juleps, &c. *₊* In some chemists' shops, the syrup of opium is substituted for the syrup of poppies; the two syrups however are not identical.

——— of Tartar Emetic (James Morgan): one grain of tartar-emetic, three grains of cream of tartar, five ounces of simple syrup. Mode of exhibition—by coffee-spoonsful for children, and by spoonsful for adults, the dose being diluted in either case with equal parts of spring-water. Used in hooping-cough, bronchitis, croup, &c.

——— of the Etherized Acetate of Mercury (Virey): one drachm of the acetate of mercury, dissolved in four drachms of pure water, and two drachms of nitric ether, and a pound of syrup of gum arabic added. Mode of exhibition—one to three spoonsful daily, as an anti-syphilitic. *₊* This syrup is preferred by some practitioners to that of Bellet.

——— of Rhatany, Ferruginous (Ricord); syrup of tolu, containing two drachms of the sub-carbonate of iron, and as much extract of rhatany in the pound. Mode of exhibition—four to six spoonsful daily, in an appropriate menstruum, in blenorrhagia and mucous discharges.

——— of Gentian, Ioduretted (Ricord): one pound of syrup of gentian, one ounce of ioduret of iron; the ioduret is previously dissolved in a little water, and then added to the syrup. Mode of exhibition: two to four spoonsful daily in an appropriate menstruum, in lymphatic and scrophulous diseases.

——— of Gentianine (Magendie): simple syrup, containing one grain of gentianine to the ounce. Mode of exhibition—in the same cases as gentian.

——— of Tar (Peraire): four pounds of tar, one pound of boiling water, digested in a water-bath for two or three days, stirring from time to time; then poured off, and two pounds of sugar added. Mode of exhibition—three or four spoonsful daily, in chronic affections of the stomach.

——— of Hahnemann; eighteen grains of Hahnemann's soluble mercury, one drachm of powdered gum arabic, triturated together in a glass or porcelain mortar, with three ounces of marsh-mallow syrup gradually added. Mode of exhibition—one to two spoonsful daily as anti-syphilitic.

——— of the Hydrocyanate of Potash (Magendie): a syrup, containing eight grains of the hydrocyanate of potash in the pound. Mode of exhibition—half an ounce to an ounce in a potion, julep, mixture, &c. It possesses the same properties as hydrocyanic acid.

——— of Iodine: a syrup prepared with the lathyrus tuberosus, and containing two grammes of iodine in the pound. Mode of exhibition—one to two ounces daily, in hop-tea or infusion of fumitory, &c., for scrophulous children.

——— of White Hyoscyamus (Chevallier): simple syrup, containing one grain of extract of white hyoscyamus to the ounce. Mode of exhibition—half an ounce to an ounce in sedative potions or mixtures.

——— of Karabe or Succinum: syrup of opium of the codex, containing two grains of the volatile spirit of succinum to the ounce. Mode of exhibition—the same as the preceding.

No. 206 **SUMMARY.** May 24.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

Chorea, or *St. Vitus's Dance*, consists in involuntary contractions of the muscles; the power of the muscles ceases, and there are uncontrolable movements of the body. In the extreme degrees of this disease these movements take place spontaneously without voluntary motion, even during sleep; but in the slighter and more common forms the motions are excited only when the limbs are acted on by voluntary efforts, so that the motions so excited, instead of being exactly in obedience to the will, wander from it and become extravagant; the movements are of an irregular kind, and not precisely such as it is the desire of the patient to make. The efforts of the will are ineffectual in directing the movements, or of arresting them when they have once begun. This kind of affection is in some instances quite partial—only one set of muscles being influenced in this way. The parts most liable are the muscles of the hands and fingers, and the neck; and, though not to so great a degree, the features are often affected, so that the patient makes all sorts of grimaces. The involuntary motions are seen in the worst cases when the patient attempts to walk; in fact, the motions are generally such that he is unable to walk, and when he does, it is a tottering or dancing motion. The act of feeding, too, is very difficult; the motions coming on just as the patient attempts to raise his hand to his mouth, so that he makes a dozen trials before he can raise a cup to his lips. These motions may often be controlled by very strong efforts; they last for a time, and then seem to be overcome. On the other hand they are increased by agitation and excitement. This is a disease that affects children, and most nervous females. It is not at all dangerous in the general run of cases, although in a few extreme cases there have supervened convulsions and coma, arising from effusion into the cerebral or medullary centres, both of the brain and spinal marrow. The exciting causes which immediately bring about the attack in nervous children, and in children otherwise predisposed, are commonly the same,—irritation in the stomach or intestines, bad food, feculent accumulations, worms; but sometimes the cause is a mental one; moral excitement of any kind has been known in many cases to induce an attack of chorea when there has been a predisposition to it before. The precise nature of the disease appears to be an excessive irritability of the excito motory system, that part of the nervous system which is intermediate between the organ of volition and the muscles themselves, the voluntary nerves, or instruments by which they are moved. This remarkable excitability may be acted on either by irritation in the body, as in the alimentary canal, or mentally; where this excitability exists, then voluntary motion, when attempted, induces it in great excess—so that when the child attempts a motion of the mouth, the motion is too much [illegible] inability to keep it within bounds. The motions not only are not of the kind intended, but they are overdone. If the child attempts to raise the hand to the mouth it goes above it. It may be said to be an irregular exaggeration of the voluntary motion. When voluntary motions have to be performed, the muscles excited to action are obedient to the will, but they overdo their part. The excito-motory function may be brought into action by pressure on the incident nerves, as in irritation of the intestinal canal, and in the irritation of teething; and hence in bad cases there is not only excessive and irregular motion during involuntary acts, but altogether a continued motion at intervals, even when the cerebral system and all its connected parts are asleep. I believe this is the view Dr. Marshall Hall takes. There can be no doubt at all that it is essentially a disease of the true spinal system. Excitability is the term properly applied to this peculiar state of the excito-motory function. With regard to *paralysis agitans*, it is something more than mere excitability; there is a continued irritation; the motion is wholly independent of the will, and goes on whether the patient is sleeping or waking, and this is probably owing to the absence of the tonic power by which the motions are controlled. Now the subjects in whom this affection (chorea) occurs, illustrate the nature of the disease. It occurs in children in whom the excito-motory system is naturally very active; fidgetty, restless children, who will always have something of this kind. It is difficult to keep the child even in health perfectly still and steady. This may be said to be a nervous disease of children, which in older subjects would be called hysteria; and female children that have chorea when young, when they get older labour under various forms of hysteria. It is commonly preceded by more or less disorder of the digestive organs; constipation, acidity of the stomach, and with this, headache is often complained of. Sometimes it happens in children otherwise very healthy. Besides this, mental causes, fright, over-exertion, and other things, have been known to bring it on. Over-exertion consists in an undue excitement of the excito-motory system. Repelled eruptions have been known to induce it; injuries of the back, and rheumatism, have in many cases been followed by attacks of chorea. It sometimes occurs in females about the age of puberty from irritation, and in girls who have menstruated, but who have not lost the habit which as children they possessed. When the disease begins from irritation of the intestinal canal, it is not always removed by a removal of the irritation, but we must apply our treatment to the nervous system which seems to constitute a part of the disease where it has existed long. I have hitherto adverted to the disease as being altogether functional, not structural; but we find in some cases in children that sometimes the disease goes on to coma and convulsions. The disease occurring in adults is more generally connected with some inflammatory or structural disease, and very rarely as a general affection. In some remarkable cases of chorea, the patients are subject to violent fits of laughter which they cannot restrain, except by holding their breath, and there are other cases on record of hysterical affections that take on the character of chorea, and are called laughing chorea. I remember a very violent case, which was induced by the habit of carrying burthens on the side of the neck.

With regard to the treatment of chorea in children, it usually yields to purgatives and tonics; if the disease is very recent, purgatives will often succeed in curing the disease; but, subsequently, the addition of various tonics is required. Purgatives remove the irritation of the intestinal canal which I before adverted to, as tending to produce the disease. Derivants are useful, in preventing the local determination of blood, which is connected with most cases of excitement of the nervous centres, but the remedies that answer most effectually in most instances are tonics. I have seen cases cured by quinine, and by bark, but metallic tonics are most effectual. Sulphate of zinc, and sesquioxide of iron are the most useful, the former being adapted chiefly to the more plethoric subjects. In children who are active and who exhibit a tendency to inflammation, without any weakness of constitution, it may be given in doses of ten grains, three times a day, gradually increased. The salts of iron may be given in various forms; the sesquioxide is the favourite remedy; it does no harm, and may be put into the hands of any one. It may be given in doses of one scruple up to half an ounce, two or three times a day. The more effectual tonics are the more soluble ones: the sulphate of iron is a very good one, but the iodide of iron, in my own experience, answers best: it pervades the system more rapidly than any other, and keeps the secretions more free. It may be given in doses of one grain three times a-day, increased to four or five grains, taking care at the same time that the bowels are open. In obstinate cases, where there is functional disorder of the spine, and the membranes of the spinal chord, counter irritation by blisters along the costal spine, or tartar emetic ointment, or croton oil, or some other applications of that kind, are useful. In these cases nitrate of silver has been found of service. If there are any symptoms of fulness, or any local pain or tenderness in the region of the spine, local blood-letting should be practised; and if the disease has originated from rheumatism, it is proper to give colchicum, and iodide of potassium internally, at the same time that counter-irritants are used. There are some other affections closely allied to chorea, and diseases of the motor functions, that may be either functional or structural. To illustrate these, I may mention some experiments made by Magendie and others on animals; on removing the corpora striata of some animals, there was an irresistible tendency to move forward; on removing the cerebellum the tendency was to move backward and forward; and the removal of considerable portions of the crura cerebelli caused them to roll over and over. In the latter case the motion was very extraordinary, for it is recorded that the animal continued to roll over and over at the rate of sixty times in a minute, for eight days in succession. There is no doubt that injury done to certain parts of the nervous system produces an undue development of the motion of particular parts of the body. Structural diseases and func-

tional disorders may incapacitate various parts, and somewhat similar results may ensue. Irregularity of the circulation by pressure, or by congestion, may produce the same effects. This may explain many anomalous cases on record, in which persons in connexion with structural disease of the brain, sometimes without any structural disease, but apparently in connexion with functional disorder, have exhibited rotary motions; hanging and rolling the head about, and swinging the arms to and fro, and all sorts of absurd and fantastical motions. Hysteria presents a type of all these things, and of every other nervous disease. The subjects affected in those cases are nervous persons, and are observed to be subject to a sort of laughing ague, an infectious disease so to speak, which was prevalent in the north of Scotland for some time, causing people to shake and laugh in a most extraordinary manner. Again Tarantulism, supposed to be excited by a poisonous influence, seems to be very much of the same kind; it is an excited state of the excito-motory function, under some narcotic influence, in which the patients dance until they fall down perfectly exhausted.

The next disease to be adverted to is, *tetanus*, which is a more serious matter. It consists of a tonic continued spasm of many muscles, causing an unceasing or at least a continued rigidity of the limbs and trunk, the sensorium being unaffected, or not essentially so. This is a spinal disease unconnected with a mental cause. There are different kinds of this disease, and it is divided according to its origin or cause, into idiopathic, which arises from exposure to cold and wet, and perhaps, from intestinal irritation, and secondly, traumatic tetanus which follows an infliction of a wound, or a mechanical injury to a nerve. There are also varieties according to the part which is affected. Tetanus does not affect always the whole body. It may be general or partial. For instance, *opisthotonos*, where the muscles of the body are drawn backwards, *emprosthotonos* where a part of the muscles of the body are bent forwards; and, again, *pleuristhotonos*, the muscles of one side being affected; and another variety, affecting the jaw is called *trismus*, or lock-jaw. These different affections may differ, according to their direction and intensity, and hence they may be acute or chronic, and there are some that are called *sub-acute*. Now, the symptoms of general tetanus in bad forms, are, that it comes on very suddenly, with some previous general uneasiness of the whole body; restlessness, constipation, dry skin, and soreness at the back of the neck, and during sleep the limbs are straightened in a remarkable degree, the disease apparently beginning at the time the voluntary influence is least exercised, which is commonly the case with regard to diseases beginning in the spinal system. The voluntary motions exhaust their influence a good deal. There is felt more or less dryness and constriction in the throat, and symptoms of spasm referred to the sternum or the diaphragm, a stiffness, and sometimes a sudden closing of the jaws; there is difficulty in swallowing, a spasmodic dysphagia coming on from time to time; the spasms affect the muscles of the face, and cause most horrid contortions; the saliva becomes very viscid, and the patient complains of the throat being parched and dry or flabby; by the constriction of the muscles of the jaws, and by the muscles of respiration becoming more and more affected, dyspnœa comes on of the most severe kind, accompanied by a feeling as if a hot iron had been applied to the epigastrium restraining the motions of the breath. Sometimes in the midst of these horrible affections, the mind and the sensibility are quite free. The pulse is at first commonly hard, and full, but it soon becomes frequent, and at last irregular and feeble through exhaustion, and in the worst cases the beats are said to rise as high as 110. The spasm comes on at intervals, but there are general remissions, and spasms that never relax, and generally rigidity is continued in some of the parts. Death takes place generally in the severe cases on the second or third day. There are some extraordinary instances in warm climates of death taking place more rapidly. In the West Indies a negro having wounded his hand or foot, in the course of a quarter of an hour fell down dead with tonic spasms. If it goes beyond the fourth day there is a prospect of recovery; and, in fact, the greater number do recover, and then the disease may be said to be of the sub-acute kind. The most formidable kind of tetanus is the traumatic tetanus, which is of the acute kind, and is, with very few exceptions, fatal. The fatal result seems to depend, in some cases, on asphyxia: the muscles contract, and press the patient to death. In other cases, death seems to arise rather from exhaustion and syncope. The disease has nothing at all to do with the severity of the wound which may have caused it, as the slightest wounds have been followed by the most severe forms of tetanus. Tetanus has been caused by surgical operations; and it has been caused by the state of the weather, when cold or wet weather have supervened after heats. Idiopathic tetanus is most commonly brought on by sleeping on damp grass. Infants are affected with it from the irritation of improper food. A few cases resembling tetanus have been produced from tænia, or tape-worm. The morbid anatomy is altogether negative; nothing has been made out. In a few cases the meninges of the brain and spinal column have been affected, and sometimes ecchymosis has been found; but in the majority of cases, there is very little after death to account for the disease. In some few cases of traumatic tetanus the nerve at the wounded part has been found inflamed and thickened. In a few cases, some traces of gastritis have been found. Idiopathic tetanus, in some few instances, strongly resembles rheumatic neuralgia, affecting chiefly the sensitive parts of the nerve, and probably, under some circumstances, affecting the motor parts of the nerve. In some instances it has been known to follow rheumatism, and to occur during the progress of that disease, and it seems to be dependent on irritation of the spinal cord. And what is irritation? We hardly know; there is much yet to be made out about nervous irritation; but there are some facts to show that nervous irritation may occur independently of inflammation, or of any known condition of the vascular system. In tic doloureux, which is a neuralgic affection brought about by a sudden cold, or other circumstances, the spasm is too sudden and too transient to be connected with any alteration in the blood; it is something to be called, for want of a better term, irritation; we see the same thing exhibited in the action of certain poisons. Strychnia irritates the spinal system in a remarkable degree, so as to produce a kind of tetanus, but we cannot say how it does so, and must only take the fact as it is. Traumatic tetanus appears to be a violent exertion of the motory function of the cord connected with the tonicity of the muscles. In recent cases, where the disease has been caused by an injury of a particular nerve in a diseased limb, when that limb has been amputated the irritation has ceased; but this is not the case where the disease has gone on long; the irritation, then, has been transferred to the spinal cord, and the removal of the cause will not remove the disease.

Now with regard to the treatment,—opium has been given in nervous cases, as much as twenty grains every three hours. In other cases, stupor has ensued if the tetanic spasm had not relaxed. A case is recorded of a patient taking 110 bottles of port wine in forty-two days, and he was cured. Cold affusion has been said to have cured a few cases. Blood-letting is not curative, but it appears to be palliative in the acute cases. Hydrocyanic acid, mercury, digitalis, and ammonia have been tried without effect. Dr. Elliotson gave carbonate of iron in enormous quantities successfully. Hamilton and Abernethy have recommended purgatives, and each one recommends his own hobby. Turpentine has been considered one of the most effectual purgatives in this disease; but this, like others, cannot effect a cure. Indeed, very few of the remedies that have been tried have had any effect towards a cure. Looking rationally at the thing, I should attempt to cure idiopathic tetanus on the same principles as rheumatic inflammation, using the strongest counter-irritants, liquor ammonia, and calomel and opium in very large doses, with colchicum, my favourite anti-rheumatic remedy. In traumatic tetanus I cannot say much about the expectation of curing this form of the disease, but there are some cases recorded of cures having been effected by Indian hemp.

COURSE OF LECTURES ON SKIN DISEASES,

By D. J. Corrigan, M.D., Physician to the Whitworth, Hardwick and Richmond Hospital, Lecturer in the Dublin School of Medicine &c.

Of the class vesiculæ the last is scabies or itch. This, I am sure, is known to all of you, but not, I trust, from personal experience. (Laughter.) I shall not take up your time by entering upon it at any length. The vesicles in scabies cannot be confounded with those of any other disease but eczema, and from these they are readily distinguished by their greater size, by their appearing on an uninflamed surface, though in scabies the skin around the vesicles sometimes becomes inflamed; the figure of the vesicle in each will help materially to assist the diagnosis between them; *in scabies it is conical, in eczema round and flat towards the centre.* The conical character of the itch vesicle may not be readily seen at a casual glance; look at it in profile, and you will at once discern it. Itch appears on the inside of the wrists and between the fingers; eczema, as you see in this plate of eczema impetigenodes, appears on the back of the hand and along the back of the fore-arm. Itch is always a vesicular eruption, except in some very rare and aggravated cases, when it becomes pustular, but it never presents the mixture of scale and scab, which you see delineated here (handing round a drawing of eczema impetigenodes). With regard to its treatment I need say no more than that its specific is sulphur.

We now come to the third class, bullæ or blebs, comprising but two varieties, pemphigus and rupia. To these are sometimes added pompholyx, but, as I think, upon no very good grounds. When the disease is acute, it is called pemphigus, and when chronic, pompholyx. I see no reason why they should not be joined together just as well as lepra and psoriasis. And with this understanding we shall proceed to consider both as but one class of the order bullæ. The only difference between a vesicle and a bulla is size. This is the sole difference between them. Pemphigus, the first variety of the class, as I have already said, has been divided by some into pompholyx and pemphigus. Pompholyx they would call the disease when the skin around the bulla, or on which it is seated is inflamed; and pemphigus when otherwise. As I have remarked already, this is erroneous. In talking thus, they seem to forget the essentials of the disease. Redness of skin may or may not accompany it; the bleb itself is the only *essential* feature of the disease, the redness being merely an *incidental* complication quite unconnected with it. Pemphigus generally attacks children, and sometimes adults. It commences with some slight degree of fever. When this has lasted for a day or so, bullæ begin to appear on various parts of the body; over the chest, abdomen, nates, and along the lower extremities. These bullæ are of a size varying from that of a hazel nut to a pigeon's egg. If the child is of a good constitution, and if care be taken not to injure them, they soon dry up, and the skin peels off, leaving a new skin underneath, just as if the part had healed up after the application of a blister; but when the child's constitution has been shattered by bad nursing, long illness, or bad treatment of any kind, these vesications acquire the character of so many troublesome ulcers. When a child is brought to you, labouring under this disease, so like is the appearance of these vesications to the effects of a scald, that at first sight you would be tempted to suppose the child had met with an accident of that nature. Here is a specimen of the disease, which represents faithfully its appearance. (Exhibiting a cast of a child's leg attacked with pemphigus.) This cast was taken by me, many years since from a patient in the Whitworth Hospital, a child who had been admitted with symptoms of fever; shortly after its admission into the hospital, the eruption made its appearance. This cast shows you the affection at its height; and in this drawing (sending it round), taken from the same patient, you perceive the appearance which these bullæ assume when broken. Pemphigus when seated over a bone, or upon the lobe of the ear, is very apt to extend to the bone

rendering it carious. This affection is liable to appear in adults toward the close of fever of a gastro-enteritic type. The nurse, or whoever is in charge, will call your attention to it, by stating that while turning him in bed she has discovered these blisters, as she calls them. On making a closer examination you perceive these blebs in greater or less number, scattered over the body, and of a size varying from that of a split pea to a hazel nut or pigeon's egg. When it occurs in broken down constitutions the vesications are apt to take on a gangrenous character, and from the fact of this termination having been observed with so much greater frequency in children than in adults, it has been termed pemphigus gangrenosus, or infantilis. Some years ago this form of the disease was very prevalent among children of a particular class in the county of Wicklow, to such an extent as to fully warrant its being called an "endemic" disease. At the time I speak of, the County Wicklow contained a great number of foundling children, sent out there to nurse. There was no house, however poor, that had not two or three of them. The consequences may be easily guessed. The children were badly nursed, and ill-treated in every respect, stinted in food of a good and wholesome quality, and deprived of a sufficiency of warm clothing. Under these circumstances it was, that the present form of this disease appeared among them, and such havoc did it commit among them, that fully ninety-three per cent. were carried off by it. And among the whole number you could not reckon more than seven per cent. who were of an age from twelve to eighteen months. But we now-a-days see nothing of its virulence compared to that of the time I speak of.

TREATMENT.

When the bullæ have been broken, and the child is of a good constitution, the parts beneath present the same appearance as in so many blisters. These soon heal up. In such cases do not apply ointments to the parts, they will only irritate, and neither should you apply lead lotions; they will not hasten the formation of new skin one jot. The best application you can now use is goldbeater's skin, which you know is a fine animal membrane; this cut into slips, so as to cover each spot, will serve as the best substitute you can use for the loss of the cuticle. Underneath this the cutis vera will soon produce new skin. In France a very common application to excoriations of this sort, is the inner skin of an egg; that of a turkey egg is generally preferred. What their motive may be for using this instead of goldbeater's skin I do not know; perhaps it may depend upon the greater scarcity of the latter article with them than with us. In cases where these spots have taken on an ulcerative action, the best application to them is the ung. hyd. precip. rub., diluted with spermaceti ointment, conjoined with the internal administration of decoct. sarsæ, with acid. nitro-mur. dil., infus. cinchon., quinine, &c. When they assume a gangrenous character, they require the same treatment as gangrenous ulcers from other causes. Here you will prescribe for the patient bark, ammonia, wine, porter, &c. in moderate quantities, to support the patient's strength, joined with strong broths, soups, animal jellies, &c., suited in quantity and quality to the age of your patient. Of the applications to the ulcerations themselves, I have found the undiluted red precipitate ointment the best. Dr. Stokes, father to Dr. William Stokes, during the time that this form of pemphigus prevailed among the County Wicklow foundlings, turned his attention very much to its history and proper treatment. He composed an ointment, which was found extremely useful in treating the gangrenous ulcers; it has since obtained a place in the Pharmacopœia, under the title of "Unguentum scrophulariæ nodosæ." We seldom or ever now meet with this disease of pemphigus in a gangrenous form.

The last of the class bullæ, is rupia: a case of which some of my present class cannot fail to recollect as having occurred at the Whitworth some short time since. This disease most commonly arises from the conjoint effects of the poisons of mercury and syphilis; when secondary symptoms have harassed the patient for any considerable length of time, the consequence is that from both causes, the constitution is broken down, and this disease, rupia, makes its appearance. However, it sometimes comes on when no mercury has been taken, and I am led to think that this was the case in the instance of the disease lately cured at the Whitworth. The history of the disease is this—you enter the wards of a hospital (and there is no one which you can enter where you will not find one or more cases of it), you turn down the bed-clothes from off a patient, and you see scattered over the body, trunk, and extremities, patches of a dark red colour. These are so from a degree of venous congestion having taken place in these patches. In a very little time they are found elevated above the level of the skin, owing to the extravasation of some dirty serum beneath. This constitutes the bullæ, and unless you pay particular attention in watching the progress of this stage, you will not be able to distinguish this bulla at all. This, if not irritated, forms a soft dirty scab, which becomes flattened at top, constituting one variety. Underneath this soft scab what do we find going on? The skin and cellular tissue beneath have taken on ulcerative action, matter is secreted, and according as this dries, it adds to the structure on the top. In another variety of it, which has been styled from the figure of the incrustation, rupia prominens, the scab thrown up assumes a conical appearance, somewhat resembling the shell of a muscle; this is produced in the following manner:—The vesicle in the first instance is small, the inflammation causing this, travels to the skin and cellular tissues beneath, causes there ulceration, which assumes a circular form, or one analogous to that of the primary vesicle. These rings of ulceration gradually extend themselves as each portion of tissue becomes successively implicated; while this ulcerative action is going on at the base, fresh portions of scab must be thrown up, each succeeding layer larger than the previous one, the effect of which must be to give the whole the conical form so characteristic of it.* I think that as far as practical purposes are concerned, you need not trouble yourselves about these divisions of rupia—it is quite unnecessary. All that you need be anxious about, is to be able to detect the disease when you see it, as none of its forms require a plan of treatment differing from the other. This disease, I think, you could scarcely mistake for any other with which I am acquainted; you might, if you saw the vesicle of rupia, be led to confound it with pemphigus, but any one who has ever seen either could never make such a mistake. As I have said before, you very seldom see the vesicle in rupia; when you do, it is flattish and ill-defined: whereas in pemphigus this is always tense, and circumscribed; but the grand characteristic between both is the state of the parts underneath the bulla. In pemphigus the surface beneath is red, vascular, and of a healthy character, healing kindly under goldbeater's skin or emp. lythargyri, softened in oil, which you place over each vesication, as a substitute for the true skin. In rupia, when the scabs are removed, you find an irregular, jagged, irritable ulcer, discharging a fœtid sanies. The question is how are you to remove these scabs? And this brings us to the treatment.

You cannot apply poultices over the number of sores which you meet here all over the body. If you wish to remove them, get some litharge plaister, thickly spread on linen or leather, cut it into pieces large enough to cover each of these incrustations; apply one such to each, and in twenty-four hours it will come off, leaving the surface beneath exposed to your scrutiny, and fit for applying the proper dressings. This litharge plaister acts by confining the perspiration to the part, which when thus confined acts as a vapour-bath to the scab, so that it becomes softened, and disconnected from its attachments, and finally comes off in twenty-four hours, adhering to the piece of plaister. If the ulcerations beneath should be in an irritable state, the best application you can use to them is the ung. cerussæ albæ, with or without opium, as you may think necessary. After this state of irritability has been subdued, you may venture to employ stimulants and among this class of remedies there are but two articles on which I can place confidence in this disease. These are iodine and argenti nitras, the former used in the proportion of five grains, and the latter in the ratio of from five to ten grains to the ounce of ung. cetacei. With these local means of cure, you must in all instances take every care to support the constitution; for do not fail to bear it in mind, that this disease invariably sets in in broken down constitutions. For this purpose, you will place your patient on a nourishing diet of animal food, with broth, soups, &c.; with or without porter and wine, as the case may seem to require. In every instance your aim should be not to stimulate the patient, but to support him with nutritious, easily-digested food. Among the medicinals from which you will derive most advantage, are those of a tonic character—cinchona, quinine, ammonia, sarsaparilla, the mineral acids, &c. Under this treatment, and by discontinuing the use of mercury, in cases where this disease has come on while using the above mineral, you will often have the satisfaction of finding your patient's case progress favourably. These ulcerations will heal up, and no new bullæ will appear. In all the cases where the bullæ have healed, you will in every instance be able to point out their previous situation: a depression in the skin, accompanied with a permanently white cicatrix, tells where they had previously existed.

It does happen that the plan of treatment, just now recommended, fails in curing the disease; under these circumstances, I have seen the most marked benefit derived from the external employment of an ointment, composed of from five to ten grains of argenti nitras ad ℥j. ung. cetacei, coupled with the internal administration of the same mineral tonic in doses of one grain, thrice daily. Under the use of this most powerful tonic, I have repeatedly seen persons recover, who had been brought to the brink of the grave by the irritating fever set up by the disease. Some of the gentlemen who now hear me, will recollect at once, that it was under the use of the above salt, that the woman improved, and finally got well, whom we had lately under treatment at the Whitworth. But the remedy, though possessing such highly curative power, and deservedly laying claim to the character of a powerful tonic, unfortunately possesses a drawback, which, in the majority of instances, completely prevents its administration. I allude to the property which it possesses of leaving a dark colour on the rete mucosum, which can never be removed, nor obliterated. But even this is not the worst; you can never be certain that it may not appear, though the discolouration be not visible while the remedy is being administered. Thus, you may have a patient taking it in January; he lays it aside without the least change in his usual complexion having been induced by it, when, lo! in March or April, three or four months after its discontinuance, this dinginess of colour may suddenly set in, never to be removed. Unfortunately, we have no means of counteracting this most disagreeable consequence of a remedy, otherwise so highly valuable, nor can we either tell, whether it will produce this discolouration, or when it will take place. These circumstances necessarily limit its administration to a class of persons—a very narrow one indeed, gentlemen,—persons, such as the old lady at Whitworth, about any future change of colour in whose skin, we feel not the slightest uneasiness, they being coloured and dyed pretty deeply before (laughter).

The next division of skin diseases is the class PUSTULÆ; of this, there are seven varieties:—Variola, Varicella, Ecthyma, Acne, Mentagra, or Sycosis, Porrigo, and Impetigo.

In making an examination of any pustular disease, of which you are ignorant, it would be well for you to ask yourselves the following question:—Is the disease before me, chronic, or acute? This you can readily learn by making enquiries into the length of time it has existed, and you will find it a piece of information which will be of very great service to you.

If the disease be chronic, it cannot be either of he first two, for these run their course in a

certain determinate length of time, and if, on the other hand, it be acute, it cannot belong to any of the remaining five, perhaps I should have said the remaining four, for porrigo, one of these, possesses characters so peculiar, that I think it should be placed altogether out of the class, pustulæ, and be made a distinct class of, *per se*. However, as general usage has sanctioned its arrangement as above, I shall not remove it thence. That arrangement has been made for the purpose of considering each of the above diseases with regard to its acute or chronic character; and, for this reason, we shall take the different varieties as they succeed each other in the list, along with the light which a knowledge of the acute or chronic character of a skin disease, throws upon its history. You will derive an additional gleam, in understanding whether the pustule be a phlyzacious, or psydracious one. To the distinguishing marks between them, I have fully adverted already, in the Lecture Preparatory to Treatment, &c., of Skin Diseases; but shall not here take up your time by repeating them, I shall merely remark that the character of the psydracious pustule belongs to one disease, impetigo, and that, wherever you find pustules possessing the characters which I have described as peculiar to the psydracious pustule, you may make up your minds to the belief, that such pustular disease cannot be other than impetigo.

In speaking of small-pox I shall not enter into minute details of the disease; for information such as this I shall refer you to systematic works, contenting myself with laying before you some points of practical importance which, as far as I am aware, are unnoticed in such works. The latent stage of small-pox, as closely as we can calculate, is about twelve or fourteen days; that is, of about the same duration as in measles and scarlatina. On the third day after a person has sickened, of small-pox, numerous stigmata, of a bright red colour, appear. On the second or third day of the eruption, the fifth or sixth of the disease, these stigmata become elevated, and contain an opaque lymph in the centre. This lymph is contained within the vesicle in different cells; it gradually softens down to real pus, and in doing so, gives rise to that appearance which is familiar to all of you, under the name of the central depression of small-pox. In a few days more this vesicle becomes more tense, and elevated above the surface, while that portion of it which surrounded the central depression shares also in this elevation, and about the eighth or ninth day the genuine pustule of small-pox is fully formed. It is now nothing more than a phlyzacious pustule, with an inflamed margin, and hardened base.

I do not know that at this stage you could mistake it for any other disease with which I am acquainted, but at its onset, you might so confound it. Suppose scarlatina, measles, and smallpox are raging conjointly as epidemics, and you wish for some criterion to distinguish at its onset, one disease from the other; by attending to, and bearing in mind the following distinctions between the premonitory fevers of each, you will scarcely ever make a false diagnosis. Recollect, that measles sets in with symptoms of severe catarrhal fever. You have watering of the eyes, sneezing, and discharge from the nostrils, irritation along the conjunctivæ and Schneiderian membranes, travelling thence to the trachea, there giving rise to croupy breathing; and finally, reaching the bronchi, where it causes either bronchitis or bronchopneumonia. In scarlatina, you have catarrhal fever, an inflamed state of the fauces producing sore throat, and difficulty of swallowing, and in bad cases it is attended by purging and vomiting, in addition to the former signs. The characteristic symptoms of the premonitory fever of small-pox, are violent pain of the back, and vomiting, which continue until the eruption comes out. After tomorrow evening we shall resume this subject.

Mr. Tuson, Mr. North, and Dr. F. Hawkins, have resigned their respective lectureships at the Middlesex Hospital School of Medicine and Surgery, and it is currently reported that Mr. Erasmus Wilson and Dr. Fownes intend following their example.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES—MORBID AND HEALTHY,

By Dr. Knox, F.R.S.E., F.R.C.S.E., Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

Lecture VI.

On the Form and Proportions of the Human Cranium

In this lecture I propose, first, examining the views of Retzius, Von Tschudi, and Van der Hoeven, as I find them stated in a memoir in the *British and Foreign Quarterly Review*; secondly, detailing, with observations thereon, the result of a careful examination of about two hundred and sixty crania of many nations and races collected in the rooms of the Phrenological Society—to which valuable collection the members of the society afforded me the readiest access in the most handsome and liberal manner, and for which I beg leave to express to them my warmest thanks.

Anatomists are greatly indebted to the editor of the *British and Foreign Quarterly Medical Review* for the partial translation of some very valuable memoirs by Retzius, Von Tschudi, and Van der Hoeven; the first, on the Form of the skull in the Natives of Northern Europe; the second, on the Original Inhabitants of Peru; and the third, on the Natural History of the Negro Race. I shall here take the liberty of making some remarks on these very valuable memoirs.

The authors of the three remarkable memoirs, partly translated, or given in extract, in the *Quarterly British and Foreign Medical Review*, seem to me, in a great measure, to keep a distinction in view, which the reviewer does not: I mean the distinction between "race" and "nation."

1° Retzius examines the comparative length of the skull and prominence of the jaws—one object in this being to determine the size of the posterior cerebral lobes, and to what extent they do or do not overlap the cerebellum; it being a well-known fact, that generally in the lower animals these posterior cerebral lobes are very short, and thus leave the upper surface of the cerebellum more or less exposed, or, at least, visible when the whole mass is looked on from its upper surface. It is right, however, to observe, that in some of the cetacea this arrangement is by no means so remarkable as in some animals placed much higher in the scale, or at least presumed to be of superior intelligence.

Retzius divides the "nations of men," (these are the reviewer's words) into the "long-headed" and "short-headed;" these terms have a reference to the greater or less over-lapping of the cerebellum by "the posterior cerebral lobes;" in the former the lobes completely cover or conceal the cerebellum from above; in the latter they do not. Each of these divisions is again subdivided into the:

Orthognathæ—upright and little projecting jaws
Prognathæ—prolonged or more projecting jaws.

The whole arrangement is as follows:—

Class I.—Long Headed.

Order 1.—Orthognathæ: Gauls, Celts, Britons, Scots, Germans, Scandinavians.

Order 2.—Prognathæ: Greenlanders, various North and South American Indians races—such as the Caribs, Bolocados, &c.—Negroes, New Hollanders.

Class II.—Short Headed.

Order 1.—Orthognathæ: Sclavonians, Finns, and other Icelandish races, Affghans, Persians, Turks, Lappes, &c.

Order 2.—Prognathæ: Tartars, Kalmuks, Mongols, various North and South American races—such as the Incas, Carracas, &c., Papoos.

Conclusions arrived at by Retzius:—1° That the form of a Swedish skull is quite different from that of the three neighbouring nations, and that they also widely differ from each other.—2° The Swedish head does not seem to have altered in any way during the last six hundred years; the posterior lobes of the brain completely cover the cerebellum. Besides the measurements to which I shall presently advert, he remarks, that the surface on which the cerebellum rests lies altogether at the base of the skull. Two hundred Swedish skulls were examined, but only four Sclavonians, or slaves; in this race, M. Retzius includes the Tschukt Poles, Russians, and many other *nations*, and, as appears to me, *races*; these, as regards the face, resemble the Swedes somewhat, but the cranium is rounded and of a quite different sh[illegible]. The number examined, however, is evidently too scanty to admit of any sweeping conclusions being based on them. Six crania of Finns were examined; they differed from both the preceding, still they were rounded. In five of the six specimens, there is an elevation in the course of the sagittal suture, which is also mentioned in the only account of the skull of the Finns proper, hitherto published.

This "elevation in the course of the sagittal suture" is "a crest;" I have been in the habit of describing these crests on the human cranium here spoken of as appearances of accidental elevation, or at least of frequent occurrence. This elevation, as it is called here, is sometimes double, sometimes single; but single or double, it forms a part of a system of crests very largely developed in man, but not limited to any race, nor apparently more remarkable in any one race than in another. It is on the head of the Oran or Pongo that such crests may be seen in all their perfection.

That the Swedish skull should differ from the Finlander or Finn was, I think, to be anticipated, but no doubt it is vastly preferable to prove such opinions by a direct examination of facts. Six skulls were, on the whole, rather few. The few Finns I have met with were alive, and were most intelligent; Dr. Roussell was one of them. He told me he came from Finlandia; he was a highly polished, cultivated, and superiorly educated person, such as you seldom meet with amongst even my own countrymen. He was evidently not a Russian, nor a Pole; my own idea was, that the race is descended from the ancient Goths or Huns; that they are not a Sarmatian, nor Sclavonian, nor Teutonic race, but *Gothic*, or Hunnish, whose chief seat is *now*, where it always has been during all the historic period, namely, in *Austria*, (their present chief seat), Hungary, and the Banks of the Danube.

M. Retzius examined sixteen Lappes' skulls; they differ from the other races, but in all these races, as well as in the Lappes, the face is European. In twelve "the elevation" (superior parietal crest) was found extending only forward however into the frontal bone. The mastoid processes are small; this seems to me a character of eastern skulls, and both in this respect and in others they seem to me to belong to an eastern race.

Greenlanders.—Of these M. Retzius examined two. In these skulls he remarks that the nasal bones are extremely small. The malar bones are of great size and give to the whole head a singular pyramidal appearance. But the term Greenlander is too vague in expression, and it is not, I think, saying too much to assert that the Greenlanders, as they are called, form neither a nation nor a race; it is quite otherwise with the Esquimaux, who seem to form as distinct a race as now anywhere exists.

That the Lappes are the remains of the ancient Scythians—the "greatest of men"—is possible enough; but not of the "warlike Scythians;" these must have been of a different disposition. I just remember seeing one Lappe family—reputed so—they seemed to me to differ from all the other races I had ever seen. Comparative enquiries of this kind could only be instituted successfully upon "large numbers," and by observers who had "travelled far," and who had observed much.

Von Tschudi endeavours to prove that among the ancient skulls of the aborigines of Peru, there are three distinctly different forms in different localities, and that in the present Peruvians the general form of the skull presents a union of the features of all the three. To this proposition there are physiological objections; if the different

forms indicate races, these races would not so amalgamate: if they merely indicate varieties, then their distinctive characters are unimportant. The observations of M. Tschudi will no doubt interest many, and will be examined whenever a translation of his work appears. He shews that the irregularly formed skull, found amongst the ancient Peruvians, occurs in children unborn, and could not, therefore, have been in them the result of pressure. The most remarkable circumstance I find in the extract from M. Tschudi's work, is his evidence in respect to the peculiar formation, or rather mode of development of the upper angle of the occipital bone; it is called by him an inter-parietal bone, and is supposed to have been peculiar to the Peruvian race. This arrangement was found by him in a very great number of young crania, and he thus called the bone *os Incæ*. The observations of M. Van der Hoeven, also noticed in this review, have a reference chiefly to the skulls of Negroes and Chinese. Ten Negro skulls were examined, but the number of Chinese has been omitted. A tabular view has been given, which we here copy, with the reviewer's explanation of certain terms; these are: "height of the skull," which means the distance from the foramen magnum to the vertex; "*length*," from the globule to the farthest part of the occiput; "*length of the vault*," from the naso-frontal suture over the vertex to the margin of the *foramen magnum*.

No. I.*

	Europeans.	Negroes.	Chinese
Height of the skull	5,66	5,47	5,70
Length of the skull	7,04	6,96	7,00
Greatest breadth of ditto ..	5,47	5,11	5,48
Breadth behind the external angular process........	3,74	3,74	3,66
Length over the vertex ...	14,67	13,81	14,71
Circumference	20,51	19,75	20,38
Length of foramen magnum	1,41	1,37	1,37
Breadth of ditto	1,18	1, 1	1,15
Greatest distance between the zygomata.†........	5,15	5,03	5,23

No. II.

	Europeans.	Negroes.
Height of the forehead.........	4,92	4,83
Breadth of ditto	4,72	4,36
Length of ditto...............	4,92	4,72
Distance between the temporal bones....................	5,47	4, 9

These measurements were taken from the meatus auditorius externus to the highest part.

With respect to this tabular view it is to be regretted:—1° that the number of Chinese skulls has not been stated;—2° that the European skulls were of no particular race, embracin gnearly all the modern kingdoms of Europe.

M. Van der Hoeven examined carefully the crania of five Kaffir skulls, and concluded from this that they belong to the negro type. This is true only to a certain extent, as I explained in 1820 and 1821, when having sent three Kaffir crania to Paris through the French naturalist, Lalande, and brought three crania with me to Britain, of those who fell near Grahamstadt, the anatomical characters of the cranium of this interesting race were first made known to the scientific anatomists of Europe.

In the course of the observations read to the American Society, it was shewn that the Kaffir differed in many respects from the true negro, but that the jaws were large, and indicated the strict affiliation of the race with the other dark races of Africa, without the smallest admission of Jewish or Arabian blood, as Sir John Barrow had conjectured to be the case, drawing his conclusions from ceremonies they employ,—such, for example, as circumcision, the abstaining from the flesh of fowls, pigs, &c., and from fish.

The following gentlemen were admitted Members of the Apothecaries Hall on the 15th May, 1845.—Samuel Taylor, Henry Julian Hunter, John Webber, Henry Edward Nankivell, Charles Ede, William Lea.

A special meeting of the Royal Medical and Chirurgical Society is about to be held, to elect a vice-president in the lieu of Dr. Thomas Gordon, deceased. Dr. Babington is recommended by the council.

OBSERVATIONS ON VARIOUS DEBATABLE QUESTIONS ON THE PRINCIPLES AND PRACTICE OF MIDWIFERY.

By Dr. Clay, Piccadilly, Manchester.

No. IV. Second Series.

Subjects:—*Uterine action in irregular contractions of the Uterus considered, commonly styled hour-glass contractions—Erroneous views of Paralysis of the Uterine Fibres—Retardation of Delivery not advisable—Rupture of Uterus—Case—Dr. Alison's views of Uterine Action—Where wrong—Dr. Churchill on irregular contractions of the Uterus.*

Having in my last observations shewn, that irregular contractions something analogous to the hour-glass in form, do exist in the uterus, I shall now proceed to shew how far these actions are governed by the principles before laid down. It is well known that hour-glass contractions take place generally after many rapid deliveries, and most frequently perhaps, where the delivery is accomplished in the absence of the accoucheur; then, the question naturally arises, why is this? Presuming the double action of the uterus I have been contending for, it is evident that the process of labour in its first stages may be perfectly natural, that is, the transverse and dilatory pains may run their proper course, and the longitudinal expulsive efforts may follow in natural order, but the latter may be so powerful as to suddenly eject the child; the consequence will be, that by the too sudden removal of the child *the pelvic pressure, on which the presence of the longitudinal action entirely depended* is removed also with the child; in connection with this pressure as a cause of excitement, there is an immediate cessation of the longitudinal action, whilst the transverse fibres are continued in action; thus a stricture is formed across the uterine mass immediately below the contained body, (the placenta) which will be immediately above the os and cervix uteri, and not in the middle of a bag, with an equal capacity at either extremity, as in the strict hour-glass form. This immediate cessation of action of the longitudinal fibres, has been called a species of paralysis, but this is not a correct term; it is more strictly an atonic state of one series of fibres, whilst another series continue in an active state; it is a mere *want of* action, not a morbid action. If it were paralytic, the natural action would not be resumed so immediately, when the stricture is overcome, which is invariably the case. Some have argued that it is a partial paralysis; this term is equally inexpressive of the truth; though it is true, only a part of the uterine fibres are in the atonic state. Another writer states that the cause of hour-glass contraction "is a want of balance between the muscular power of the fundus, and that of the centre of the uterus, the former being in a state of paralysis, and the latter in a state of spasm:" to justify this opinion it is argued that opium overcomes the spasm of this species of contraction; this however is not a sufficiently satisfactory explanation, as opium will also often control the natural action of the uterus, which cannot be called justly spasm. This opinion however, as to the double action of the uterus, is exactly what I am contending for. To prevent hour-glass contraction, it has been recommended to retard the process of delivery, by checking the advancement of the child's head; now I contend that this species of contraction very seldom if ever, takes place in the hands of a prudent, and experienced practitioner, simply because he takes good care not to have his patient placed in any outrageous position or circumstances likely to favour its coming on. It usually happens in a practitioner's absence, the patient often self-delivered, whilst perhaps standing, or walking, or from some indiscreet efforts on the party assisting, and therefore is not an uncommon occurrence in the practice of midwives. Retardation of birth then, is inapplicable in almost all cases of this description, for if the practitioner is not present he cannot apply it, and if hour-glass contraction occur, *he having been present* in the earlier stages of the labour, it is probable his own practice is wanting in experience and capable of improvement. As to checking the advancement of the head, it is necessary this should be done *with great caution*, if the efforts of expulsion are very powerful, and a determined resistance be given against the quick advancement of the head, a much greater evil than hour-glass contraction may in all probability take place, which is neither more nor less, than *rupture of the uterus*. The frequency with which the head advances, and retires, in first labours, has been advanced as a natural process of retardation, admitting of a better dilatation of the parts; this, however, is no justification for a similar process, under different circumstances. I will not pretend to say but that retarding the advancement of the head may be unattended with irregular contractions of of the uterus, yet I have no hesitation in stating that such a practice (as a general application) is most pernicious, and its adoption will, in all probability, lead to a fearful responsibility; for if one case of rupture of the uterus could be traced to its application, it is enough to condemn it in practice. A circumstance of this nature occurred to a young friend of mine. some years ago, he was attending a case, and as the dilating pains were few, and far between, he went down stairs, and throwing himself on a sofa, soon fell into a sound sleep; two hours elapsed, when the pains suddenly changed to the expulsive character, violent, and rapid, so much so, that one of the females placed her hands externally, and forcibly prevented the advancement of the child's head, whilst another female went to rouse the medical attendant (which was not very easy, he being much fatigued); on going up stairs, he heard a most terrific scream, and soon became aware of the awful fact,—the uterus had ruptured, with the head on the perinæum, against which, the female was still forcibly exerting herself. On the whole, I question the propriety of retarding the advancement of the child's head, with the view of preventing irregular contractions of the uterus subsequently; indeed, I believe it altogether unnecessary, even with the idea of preventing lacerations of the perinæum; which, I think, is satisfactorily shewn in my essay on that particular question, in a former volume of the Medical Times. In cases of very rapid deliveries, I am strongly disposed to conceive, that if the uterus continues entire, there is a great difficulty in checking the advancement; the commencement of the pain is so instantaneous and unlooked for, and the result so immediately after, that the mischief is often accomplished before any pressure could be applied; it must also be considered, that most frequently in these cases, the patient is in some awkward position (standing or walking, &c.) and the person to assist, generally absent. It is better, therefore, to avoid retardation of the process of delivery. But to return to the question of uterine action; the views I have hitherto advanced, are, in a great measure, borne out by practical facts, and I have no doubt of their correctness. In the year 1841, Dr. Alison read a paper before the Medical Society, On the Immediate Causes of the Contraction of the Womb, &c., &c. Dr. Alison's views are, in respect to the supply of nerves, exactly those which I have given in the early part of this paper; but he seems altogether to have misunderstood the application of his doctrine; he denominates the whole action of the uterus, *expulsive*, and the stimulus to that action, *to be the uterine contents*; than which, nothing can be further from the truth. I have shewn that the first *natural* efforts of the uterus are dilatory, which are brought into action, not by *the uterine contents*, but by the arrival at, of a *certain degree of tensity* of the transverse fibres of the uterine structures. The second efforts of nature are expulsive, and the excitants to the latter action, are the contents of the uterus, producing pelvic pressure, and thereby exciting the longitudinal fibres; and that frequently, hardened fœces, tumours, and vaginal explorations, will produce the same result. It is evident that the contents of the uterus cannot be the exciting cause of expulsive action, since that action continues long after the contents are entirely expelled, and this is very satisfactorily shewn in cases of severe after-pains, which are of the *expulsive character*; it is true, the contents of the uterus no longer pro-

duce pelvic pressure, but the uterus has become entirely pelvic in its situation after labour, and is, for some time subsequent to labour, abnormal in its size; it, therefore, is *itself, as an organ, the excitor of its own contractile efforts*, which continue until its normal size and position are attained. *If*, in the first action of the uterus, we discard *the maturity of tenuity of the transverse muscular fibres*, and attribute the immediate cause to the *uterine contents alone*, to what absurdities and uncertainties it would ultimately lead us.

In Dr. Churchill's very able work on Practical Midwifery (a work which I have no hesitation in saying ought to be in every accoucheur's hands), the chapter on irregular contractions of the uterus, is not so fully drawn out, or so well illustrated, as the other parts of the work. In my next communication, I shall conclude this essay by pointing out where I respectfully differ from Dr. Churchill's opinions, and illustrate my own views by practical illustrations.

(To be continued.)

OBSERVATIONS ON HYDROPHOBIA; WITH A CASE OF SUCCESSFUL TREATMENT.

By John Hooper, M.D., M.R.C.S., &c.

At a very early period after the commencement of my professional studies, I had the good fortune to see a very interesting case of this disease, which occurred at Chatham. Never shall I forget my first entrance into the chamber of the afflicted little girl. All was silence until the door was opened, when her watchful and suspicious eyes were directed towards me with an expression of horror and a loud exclamation; the admission of a current of air produced her distress. She soon recovered and talked most coherently, complaining of pain in the stomach, excessive thirst, frequently putting her hands to her throat, and begging for drink, which her attendants feared to give her, on account of the distress it invariably produced on being presented. She had made numerous efforts to swallow fluid without avail; now, in consequence of her vehement entreaties, they gave her some water, the sight of which produced so severe an attack of spasm, that it required the combined efforts of her mother and friends to keep her in bed. I well remember the contorted countenance and foaming mouth; in a few minutes she appeared to recover her senses, and had much trouble in spitting out the cohesive saliva. She was very solicitous to be held fast when the fits occurred, lest she should bite, and communicate the disease to others, crying out in a peculiar croaking voice, "I am sure I shall bite you if you do not hold me." Everything was done that skill and the united experience of the most renowned medical gentlemen of the place could devise to alleviate the dreadful sufferings of the poor patient, without success. Opium, mercury, antispasmodics, and bleeding were tried; she died about fifty hours after the attack. The wound which had cicatrized, became painful a few hours after the seizure; before her death the wound discharged freely. This case made a strong impression on my mind, and was the cause of my selecting hydrophobia as the subject of the required inaugural thesis at my graduation. The whole subject of treatment does not appear less difficult and afflictive now than then. Long was the catalogue of medicines, many, in their day of great repute (some accounted specifics). With what confidence have the following been recommended by men standing high in the profession:—Radix mundo, eau de luce, cantharides, lichen terrestris cinereus Raii, in consequence of its supposed specific properties named by Linnæus Caninus; 1721, admitted into the London Pharmacopœia, combined with black pepper, under the title of pulv. antilyssus: musk, opium, belladonna, nux vomica, tobacco, stramonium, arsenical preparations, alysma plantago (madwort plantain), genista tinctoria (butcher's broom), and mercury. Of all these remedies, the latter *a priori*, appeared the most efficient antidote; it was first brought into repute by M. Dessault, a Frenchman, who, in the early part of the seventeenth century published four cases of persons who had been bitten on the same day by the same mad wolf; two had all the symptoms of hydrophobia. These were successfully treated by the free use of mercury, until salivation had taken place. Many years subsequently seventeen persons were bitten by a mad wolf: these cases were under the care of Dr. Wolf, of Warsaw; two only were treated with mercury; ung. hyd. ʒi was rubbed over the cicatrices daily, and they were purged with calomel; no antispasmodics given; ptyalism was not effected; they died. Dr. Wolf after such inefficacious treatment, ventured to discard mercury, and therefore again brought it most undeservedly into disrepute; in every case in which it has been tried since, wherein the patient was really labouring under entasia lyssa, or hydrophobia, the consequence of a bite from some rabid animal, the sufferer has been carried off by the nervous symptoms before ptyalism had taken place. I therefore resolved that if a case should ever come under my care, to give it a fair trial; removing the spasms by stronger antispasmodics than had heretofore been given. During the existence of this disease, there is every indication of an inflamed state of the mucous membranes of the trachea, bronchia, and of the stomach; and the like indication of meningitis. *Post-mortem* examinations evince an inflamed appearance of these membranes. For arresting inflammation of this kind we have not a more powerful remedy than mercury, assisted by topical and general blood-letting. Independent of its supposed specific properties, a virus is certainly introduced into the system. Infection is communicated through the medium of saliva, and the recipient has fresh virus again poured forth by the salivary glands; no medicine, certainly, has so powerful an effect upon the glandular system as mercury, therefore if it has the power of destroying the virus, it must here be brought into conjunction.

I had not been in practice many years ere an opportunity occurred for adopting my plan. One Friday, about eleven o'clock, P.M., in the month of September, 1825, I was requested to visit Reuben Piper, aged seventeen, groom to Mr. Holbrook, of Aspeden Hall; on my arrival the latter described the state of his servant, who, he informed me, had been bitten by a mad dog, about three weeks since. The said dog had bitten a man in the leg, who immediately went to a surgeon, and he extirpated the part: no ill consequences ensued—a cow, pig, and another dog had been bitten—all were killed as soon as rabies was manifest. The offending dog, immediately on its showing ferocity, was chained up in the stable. Reuben Piper, the groom, who with his arms bare had been rubbing down the horses, unfortunately approached too near the dog. It seized his arm and inflicted a severe wound. Mr. Holbrook and family were then at Tottenham. Reuben, without consulting his master, rode to Puckeridge to obtain some drink from an old veterinarian of that place, who long had the reputation of preventing ill consequences accruing from the bite of rabid animals; the wound shortly healed; and he continued to take most copious potations of the said drink until the day before I was summoned. I was now introduced to the poor fellow; for some days antecedently he had laboured under great nervous agitation, and considerable depression of spirits; he was now in a violent paroxysm, requiring four persons to hold him, struggling from side to side. The spasms were most severe, with the most horrid and terrific distortion of countenance. He foamed at the mouth, an abundance of viscid saliva flowing thence; he made a noise, which the attendants compared to the howling of a dog; he attempted to bite those who were holding him; the attack continued about six minutes, during which the pulse was so quick that it could not be counted; as soon as he ceased struggling and the spasm subsided, he was perfectly conscious and his ideas collected; was very watchful, urging us to be careful lest he should bite; he would be very sorry to do so, but had a great inclination when, to use his own expression, "he was very bad." Occasionally he complained of great thirst, and pain in the stomach, tightness across the chest; one of the servants poured some water into a vessel behind him; the sound of the fluid brought on a spasm; between the attacks, his nerves became exceedingly sensitive; the least noise in the room, walking by him, moving any article, the slightest current of air, the door being opened, increase or diminution of light, moving of a shadow on the wall, appeared to distress him. The sight of a glass tumbler brought on a paroxysm; the fits would cease for a quarter of an hour. He had pain in the pit of the stomach, which would be discontinued, then he had a pain in the bitten arm—these pains frequently alternated; on examination it was found red; there was no discontinuity of surface; a large cicatrix was evident. I was informed that at breakfast he drank two cups of tea; all the day he had complained of itching of the cicatrix in the arm which had been bitten; he had frequently rubbed it. At one o'clock he sat down to dinner with the servants, but could neither eat nor drink, yet complained of parching thirst; four o'clock, being excessively thirsty, he went to a public-house for some beer—attempted to drink, it produced a sensation of horror; he then asked for water—when produced he shuddered and turned away, leaving the house without attempting to drink. The jaws were separated by a piece of wood placed between the molares. I then with an iron spoon conveyed into the pharynx two drachms of tincture of opium and the same quantity of spirits of camphor; a few drops were forcibly ejected by the violence of the spasm; ten grains of calomel mixed with honey were placed under the tongue; three drachms of mercurial ointment were rubbed into each axilla, and the same quantity on the thighs; in half an hour the same dose of laudanum and camphor was repeated, the convulsions having returned with pain.

One o'clock a.m. Saturday.—Paroxysms not so severe.

> ℞ Tinct. opii
> Sp. camphoræ aa ʒj.
> fiat haust
> Quamprimum habeat
> Admoveantur hirudines xii scrobiculo cordis
> Mittatur sanguis ad ℥xx saltem

2 o'clock a.m.—More tranquil, free from pain; thirst; on being asked to drink some tea, with horror he shuddering exclaimed, "O no! O the tightness in my throat." The cicatrix in the arm has given way; he has a slight discharge from the wound.

4 o'clock a.m.—No sleep, perfectly sensible, restless; thinks he must die; free from pain; although he has taken within four hours 300 drops of laudanum and the same quantity of spirits of camphor, there is not the slightest tendency to delirium; he has had no paroxysm for an hour.

10 o'clock a.m.—He did not sleep until 5 o'clock; he continued in a sound sleep until 9, when he asked for drink; they gave him some water, which he drank without inconvenience.

> ℞ Pil aloes, ℈i
> Pil hydrarg. gr. x, fiant pil vi
> Statim sumendæ.
> ℞ Magnesiæ calcinat, ʒi
> Mannæ, ʒiv
> Tinct. hyoscyami ʒij
> Mist. camphoræ, ℥v; fiat mist.
> Capiat quartam partem omni quadrihora.

Six o'clock p.m.—Ptyalism has commenced; he has been sleeping nearly the whole day, and perspired most profusely; has taken gruel occasionally.

Sunday morning.—Mouth very sore; copious flow of saliva; bowels have been well opened; dejections very dark.

Repetantur mist et pilulæ sine hydrarg. pil.

7 p.m.—Bowels have been well evacuated; less thirst; pulse 95, small; only complains of weakness; has eaten some pudding; no unpleasant sensation when he drinks.

On Monday he returned to Tottenham convalescent; mouth sore.

I saw him about a year after his recovery; he was then suffering from some aberration of the digestive functions—continued under my care a few days.

Case III.

September 7th, 1829, I was requested to see Sarah Knights, ætat. 13, at Standon.—11 o'clock, p.m. This poor child had been under the care of Mr. Packman, of Puckeridge, whom I met in consultation; she was labouring under all the

symptoms of hydrophobia, the consequence of a severe bite she had received in the face about four weeks prior to my visit, from a mad-dog belonging to the Rev. H. Law, rector. It is scarcely necessary to record the symptoms, which corresponded in every feature with this most terrific and appalling disease.

The bitten parts were somewhat inflamed and painful; pulse 160, intermitted considerably, very small. The sight of glass produced the same distress as water,—the slightest agitation of the air; some persons present happened suddenly and carelessly to withdraw his handkerchief from his pocket, even this produced a severe attack of spasm, with horror; she frequently attempted to spit out the accumulation of viscid saliva. It was quite evident there was little prospect of success; the poor sufferer had been struggling with this direful disease twenty-eight hours; she was nearly worn out. I administered the following draught, taking the same precautions as in Reuben Piper's case:—

℞ Sp. camphoræ
Tinct. opii aa ʒj.
Aquæ font ℥ij.—fiat haust.

The whole was swallowed; five grs. of calomel, with honey, were placed under the tongue. A drachm of blue ointment was rubbed into each axilla.

I remained with the little sufferer an hour; before leaving, gave the same dose of laudanum and camphor; and requested that it should be repeated during the night, if the same consecution of distressing symptoms continued; also, that the mercurial friction be repeated in four hours. I called the next morning; the poor mother reported that she passed a more tranquil night: there had been no delirium; she slept for a short space; paroxysms less frequent and violent; yet it was evident to them she became weaker, and was sinking; she drank fluid two or three times, with little difficulty; frequently during the night had repeated her persuasion, that if the same treatment had been tried before, she would have recovered; that now she must die:—she resigned her spirit about 4 o'clock, A.M., five hours after my first visit; no symptoms of ptyalism had taken place.

It is quite clear, large doses of opium or laudanum only, are of service, and can be given in this disease without danger.

If administered in the form and proportion recommended, or combined with ether, on the supervention of the disease, simultaneously with plentiful mercurial inunction, that is to say, for an adult, not less than ℥j. within a few hours, and in such parts of the body, where it will be with most facility absorbed; with general and topical depletion, I am sanguine that the treatment will be successful, and shall be amply rewarded, if by my professional brethren it is found so.

Buntingford,
May 12th, 1845.

PROGRESS OF FRENCH SCIENCE

FROM OUR OWN CORRESPONDENT.

Paris, May 8, 1845

Acute Phthisis.—R—, ætat. 5 months, for the first six weeks of his life, was not suckled, the mother having no milk; after this, however, he took the breast, and though there was a plentiful supply of milk, he still remained weak, and puny. On his admission into the wards of Professor Trousseau, at Necker Hospital, the 31st January, 1845, the little patient presented the following symptoms:—cough, which was not by fits, and had none of the characters of pertussis; no diarrhœa; mucous râle; here and there, sub-crepitant rhonchus. A blister was applied on the chest. 21st Feb.—The sub-crepitant râle had disappeared; the mucous râle alone existed; in other respects, the child was much the same, the cough being paroxysmal. 22nd.—Appearance of several aphthæ, which yielded to an application of the sub-boras sodæ. 23rd.—Fever intense; dyspnœa. 24th.—Sub-crepitant rhonchus in both lungs; blister on the back of the thorax. 25th.—Face pale; body cold; dyspnœa extreme; alæ narium considerably agitated; pneumonic furrow highly marked; pulse frequent; sub-crepitant rhonchus not so minute; no bronchial respiration; patient cannot take the breast, and swallows with difficulty. Draught, with syrup. ether. ʒj. No change; died at 7 P.M. *Autopsy*, fifteen hours after death. *Thorax.* The lungs were crowded with an innumerable quantity of small tubercles, not yet softened; in one of the lobes there existed a tubercular mass, in its nascent state, about the size of a bean; both the inferior lobes, almost all the middle lobe, and the posterior and inferior portion of the upper lobes, were of a red colour, were easily torn, and seemed to be affected with red hepatization. All the lymphatic glands of the bronchi were tubercular, but not tumefied. *Abdomen.*—Spleen full of tubercles; mesenteric glands not swollen, but containing tubercles; tubercular granulations in Peyer's glands; liver, kidneys, and stomach, healthy. *Cranium.*—Nothing abnormal; no granulations in the pia mater.

On Resection of Portions of Bones.—In a memoir read by Dr. Chassaignac, before the *Societie de Chirurgie*, the author examined the differences presented in the length of the coronoid process of the lower maxilla; for instance, sometimes when the lower jaw is placed on a flat surface, the condyle is higher than the coronoid process, whilst in others, the contrary is observed, the latter being as much as an inch longer than the former. This last circumstance led Dr. Chassaignac to divide the coronoid process ere he disarticulated the condyle, and he founded this opinion on the following reasons:—That when it is not done, the point of the bistoury being hid from the operator, it acts with considerable difficulty, and inconvenience. That the direction in which the instrument must necessarily be placed, is more and more parallel with the process, according to the length of the latter, and it acts most unfavourably in dividing the aponeurosis, and strong tendons, which cover the process to a certain extent. Finally, the condyle, being still fixed in its cavity, prevents the operator performing the movements requisite to facilitate division of the temporalis. These difficulties may be avoided, by operating as follows:—1°. Divide the coronoid process with Liston's pincers. 2°. Disarticulate the condyle. 3°. Remove the remaining portion of the coronoid process. The author next gives the rules which ought to guide the operator in resections in general, and which consist in making, as much as possible, but one incision, generally rectilinear, sometimes curvilinear; in sawing through the bone before disarticulating it; in removing separately the bones, when two or three compose the articulation; describes a modification he has adopted in the needle invented by A. Cooper, by which the application of the chain-saw is made much easier, and the way in which each operation (clavicle, acromion, head of the humerus, elbow, wrist, metacarpal bones, femur, knee, instep, metatarsal bones, lower maxilla) ought to be done, and finally concludes, that the methods he proposes are more advantageous than those hitherto employed. 1°. Because there is less tearing of the soft parts when a single incision is made. 2°. Because the deformity resulting from the multiplicity of incisions is avoided. 3°. Because the most difficult part of the operation, viz., disarticulation, is performed with greater rapidity and facility, for when the bone is divided, the mobility of the parts renders enucleation easier. 4°. Because the operation is not so long, there being fewer parts to be dissected. 5°. Because coaptation is easier, the chances therefore of union by first intention, if not being greater of the whole wound, at least in the greater part of its extent; the cure therefore is much more rapid. 6°. Because the division of a great many nerves, tendons, and vessels, is thus avoided, for the incision being generally longitudinal, *i. e.*, parallel to the axis of the limb, the bistoury cuts the skin, and subjacent parts, in the same direction. Now, in the ordinary methods, by a transverse incision, the operator runs the risk of wounding these important parts. 7°. Because sometimes before commencing the operation, it is impossible to say how much bone it may be necessary to remove; if there be but little, fewer parts are wounded when a single incision is made, and it is for this reason that, in applying the trephine, a curvilinear incision, or one in V, ought to be preferred to a crucial; besides which, in commencing with a single incision, the operator can always make others when he finds them absolutely necessary.—(*Annales de Chirurgie.*)

On Aphtha Infantum.—In a series of articles published in the *Journal de Medicine*, Professor Trousseau and M. Delpech give an elaborate and practically useful description of this disease. After stating that the characteristic eruption is formed of a fibrinous pseudo-membrane, situated on the mucous membrane of the digestive organs; the authors study the affection under the following heads—I. SEAT—in the various portions of the digestive canal from the mouth to the rectum; as to the opinion of its existing simultaneously throughout its whole extent, the facts are not sufficiently evident to authorize attaching such importance to it as is generally done. II. CAUSES—are divided into—1° *Local causes:* uncleanliness of the mouth; acidity of the saliva; normal desquamation of the epithelium; use of teats; friction of the cheeks on the alveolar edge while sucking. 2° *Those which produce only a local action, though acting on the whole system* (*a*) *age;* most authors consider this disease as peculiar to children; Dr. Valleix never witnessed it in children upwards of two months old; others deny its existence in adults, but the authors observed it in nine children from two and a half to twenty two months old, and in the mouth and vulva of adults affected with phthisis. (*b*) *Confined air in hospitals:* Dr Lebat states that it exists but at the Foundling and Venereal Hospitals, but cases are recorded which prove that it may exist in other localities. (*c*) *Climate and temperature;* further researches are requisite ere a positive conclusion can be drawn. (*d*) *Contagion;* though it may be propagated by contagion, yet in the generality of cases it is produced by an epidemic influence. 3°. *Those which act primitively on the whole system, and secondarily on the mouth.*—(*a*) *Puerperal diathesis.* In the mother it shows itself by the development of metritis, metro-peritonitis, uterine phlebitis, phlegmasia alba doleus, &c., and in the child by phlebitis ombilicalis, erysipelatous peritonitis, ophthalmia purulenta, aphthæ. (*b*) *Enteritis.* According to Dr. Valleix aphthæ form part of this affection, and increase the danger; the author considers that in general the simultaneous appearance is merely a coincidence, and that the danger is augmented from their complicating each other. Sometimes, however, enteritis may precede aphthæ, when the patient is weakened by the long continuation of the diarrhœa and vomiting; this is principally observed in somewhat older children, and it then produces the eruption in two ways—in irritating sympathetically the buccal mucous membrane, and in predisposing, by the modification of the blood, the organism to the formation of pseudo-membranes. It is in this latter mode that this affection is produced in phthisical patients, from the intensity of the febrile symptoms, the sympathetic action of the intestinal phlegmasia on the buccal mucous membrane, and the action of the saliva, which is always more or less acid on this surface. If aphthæ are more frequently observed in children, it is probably owing to the peculiar circumstances in which the patient is placed, the fragility of the integuments, and the greater plasticity of the blood.—(*c*) *Certain cachexiæ*—III. SYMPTOMS. 1°. *Of the idiopathic form.*—A few days before the eruption takes place the mucous membrane becomes dry and shining; conical eminences are perceived, giving to the parts a granular aspect; colour varies, sometimes of a dark red, at others pale; the membrane appears thicker and velvet-like, is infiltrated with a greater quantity of serosity, and is affected with inflammatory œdema; after the precursory symptoms, some whitish semi-transparent spots make their appearance retaining the form of the eminences on which they are developed; sometimes in the course of three or four days they run through their different periods; in the last stage their colour may be of a brilliant milky white, or a dirty yellow or brown; the two last however, are owing to the remedies employed; the pseudo-membrane is very adherent at the commencement

of the disease, so much so, that it cannot be removed without producing a slight hæmorrhage; at a later period it can be detached with facility. This takes place more or less rapidly according as the spots increase in size or remain stationary, because, in the former case, the spots which develop themselves around the old ones prevent their being removed; the adherence is also different according to the age, being greater as the child grows older; the pseudo-membrane separates sooner when the salivary glands secrete abundantly, or when the child drinks freely; the parts it affects are principally the lips, the tongue, and the cheeks, seldom, if ever, the fauces and œsophagus. The danger is not always greater when the eruption is confluent than when it is discrete, for the latter may sometimes be productive of serious consequences, whilst the former may go through its various stages without giving rise to any accident; the heat of the mouth did not seem to be notably augmented; pain, evident from the cries of the child whenever it took the breast; no general symptoms. A curious phenomenon took place when the disease disappeared; it consisted in an eruption of small red spots, some of them above the level of the skin and terminated by a small vesicle; this eruption does not appear on any particular spot, and soon disappears. The duration is, on an average, from eight to twelve days; its termination is never fatal. 2°. *Of the symptomatic or dangerous form.*—In addition to the symptoms just enumerated, others here exist. (*a*) Diarrhœa may appear at the same time as the thrush, or be consecutive to it; in the former there may be a solidarity of causes, but in the latter this is no longer the case. (*b*) *Erythema* is peculiar to infancy, though it may sometimes be observed in exanthemata; it presents two stages:—in the first the skin is of a dark violet red colour, which disappears partly on pressure and becomes dull brown; it sometimes covers the buttocks and part of the thighs; as to the secondary eruption, the authors, with Ketelair and Arneman, consider it to be vesicular; in some few, however, it was difficult to assert that they were not papular; be this as it may, it is but transitory, the epidermis soon disappears and leaves superficial, round, and dark red excoriations. The cause of this eruption is the irritation produced by the urine. (*c*) *Ulcerations of the malleoli* or, rather, *ulcerous diathesis*, never manifest themselves except in very young children, in whom the change which takes place in the skin after birth is not yet finished; the redness becomes transparent, is excoriated at an early period without being preceded by a vesicle; these ulcers are produced by the pressure of one ancle against the other. According to Dr. Valleix, of these three symptoms, erythema shews itself first, for, in seventeen cases out of twenty-three, it preceded the aphthæ six days on an average; in five cases, the diarrhœa appeared first, in four both together; the researches of the author led to an opinion diametrically opposite, since the diarrhœa was, in the generality of cases, the first symptom that appeared. (*d*) *Ulcerations of the buccal mucous membrane* are situated generally on the roof of the mouth or the gums; more or less deep and numerous; edges irregular, soft, red, or whitish; in their intervals the mucous membrane is of a dark red, sometimes violet-colour, and very painful. (*e*) Enteritis and its concomitant symptoms, such as swollen abdomen, and painful diarrhœa, vomiting, and fever. When the disease terminates fatally, the pulse gradually loses its force, the emaciation is very great, skin as if stuck on the bones, that on the forehead full of wrinkles, Hippocratic facies, torpidity, with convulsive movements from time to time, and finally, death. IV. TREATMENT.—The different measures may be comprised under the following heads:—1°. *Preservation* may be classed thus—(*a*) *birth-place:* children born in the wards of hospitals are more frequently and dangerously affected; this may be avoided by diminishing the number of beds in each ward, by isolating persons suffering from contagious or epidemic diseases; and even if the contagious principle be not admitted, still may not the penetrating odour emitted by a woman recently delivered, if not neutralized by appropriate measures, become the cause of this disease in individuals who are pre-disposed? (*b*) *Abode:* The unanimous opinion of the various authors who have written on this subject, proves how necessary it is to make a good choice. (*c*) *Alimentation:* lactation has an immense influence on the termination of this disease; thus, out of fifty-one children, twenty-nine were suckled by their mothers, and twenty-two not · the deaths were—of the former, seven; of the latter, seventeen. Lactation may, therefore, be considered as beneficial, whilst other modes of alimentation are more or less injurious; and it may not only render the termination favourable, but is likewise an excellent remedy, and in this respect it acts in two ways—in improving the general health, and in furnishing an aliment appropriate to the physiological condition of the digestive organs. (*d*) *Temperature:* the child must be clothed so as to avoid all sudden changes from hot to cold. 2°. *Local Curative.*—On the appearance of the eruption, to the hygienic means, the following must be added—℞. Sodæ borac. mell. optim. aa. p.e., the parts to be rubbed with this mixture; if this be insufficient, alum may replace the borax, or what is still more efficacious, hydrochloric acid when the patient has no teeth, or the azotate of silver in substance or solution—℞. Nitr. argent. ʒss. Aquæ distill. ℥ss.—in the intervals of the cauterisations, the mixture of borax must be employed. Dr. Bretonneau covers the parts with calomel mixed with a mucilage of gum arabic. 3°. *Treatment of the constitutional condition and complications.*—When enteritis exists, the most appropriate remedies are ipecacuanha in doses so as to cause vomiting—℞. Bismuth. subnitrat. gr. ij. gr. iv. sacchar. alb. gr. xviii. pulvis. Pulvis calculi cancrorum.—℞. Calomel gr. j. sacchar. alb. grs. xviij, M. ft. pulvis, in doses equales ij. vel. iij. dividendi:—or, ℞. Calomel gr. ij. carb. calc. ℈ij. tinct. opii. gtt. j. M. ft. divide in doses pulv. vj.—Decoctum album.;* rice water, starch, enemata. When the symptoms are still more intense, we must have recourse to monesia, bistort, ratanhia, catechu, and tannin in enemata, and azotate of silver, as follows:—℞. Argent. nitr. gr. 1-5th., syrup, simpl. ʒ v., aq. distill ℥j., M. ft. haustus—vel. ℞. Argent. nitr. g. j. aquæ distill ℥vjss. M. ft. enema. Against the erythema frequent lotions with ℞. sulph. zinc. ℈j., aquæ distill ℥iiss. M. ft. lotio., or with a weak solution of acetas plumbi. Finally, to prevent the ulceration of the malleoli, the limbs must be kept carefully separated by soft linen; and should this not suffice, the feet and insteps must be carefully covered with strips of sticking-plaster. V.—STATISTICAL TABLE. Of the fifty-eight cases related, there were thirty-one boys, and twenty seven girls—the termination, cures 23, deaths, 25: of the remaining ten, eight left still ailing, and in two the result is omitted. The age varied from four days to twenty-three months.

In two, the precise epoque of the commencement of the disease was unknown. In fourteen cases there was no complication; thirteen recovered, one died (the mother was affected with icterus). As to the complications, in twenty-one the diarrhœa appeared first; in nine others as a sequela; in eight the first symptom was the erythema (five of these patients presented no diarrhœa); in seven others it was a sequela; in seventeen cases intense vomiting took place. Two cures—two left the hospital after the disappearance of the thrush, but still dangerously ill; one was affected with tubercles; one, when apparently well, was seized with pleuritis, which proved fatal; eleven died. In fourteen cases ophthalmia existed. The duration varied; it was in the fatal cases—in eleven, from two to five days; in two, from five to ten days; in seven, from ten to twenty days; in three, from twenty to forty days; and in two, for three months. In the patients who recovered: in three, from four to five days; in six, from five to ten days; in five, from ten to twenty days; in five, from twenty to thirty days; and in one, two months and a half. Finally, as to the month, in which it was the most prevalent, the result was:—

Hygiene des Femmes.—Dr. Desbruères has, under the auspices of Dr. Tanchon, (who, as physician to the Dispensaire St. Genevieve, has frequent opportunities of studying the diseases to which the sex is subject,) just published a little volume, in which he indicates, in a clear and simple style, the precautions a female ought to take in order to preserve good health. This work, preceded by some remarks by Dr. Tanchon, is divided into three parts: in the first are comprised the diseases which may be caused by disturbances of the catemenial flux, by pregnancy, by accouchement, by the cessation of the menses, and the means by which they may be cured:—in the second, the diseases of the breast are described:—finally, the third includes all the hygienic means especially useful to women. In conclusion I will add, that it may be usefully and safely placed in the hands of every married female.

Academy of Sciences.—Sitting of the 5th May. M. E. de Beaumont in the chair.—Received. "On the Physiology of the Human Voice," by Mr. F. Romer. "Proceedings of the Academy of Natural Sciences of Philadelphia," Jan. and Feb., 1845. "Athenæum" Jan. and Feb., 1845.

Dr. Jobert de Lamballe writes to request, that his two memoirs, read before the Academy, and entitled "On the Electric Apparatus of the Torpedo," and "On the Establishment of Nervous Action in Autoplastic Flaps," be submitted to the Committee, for the prize of Experimental Physiology.

On the Utility of the Diapason in Diseases of the Chest and Head. By A. Latour, M.D. M. Desprez, at the close of his memoir, read at the last sitting, expressed the hope that his communication would cause researches to be made, so as to prove the utility of the diapason in pathology. The wishes of this learned Academician have been forestalled, for in two articles, published in 1843* I drew the attention of practitioners to the application of the diapason to the diagnosis of diseases of the chest. There are numerous cases in which percussion cannot be performed, for instance, when issues or blisters have been applied, and when an eruption, caused by friction with the unguentum tartari emetici, has been produced on the thoracic parietes, the diapason may be employed advantageously, instead of this previous mode of diagnosis. The vibrations of the instrument are more or less intense, according to the permeability of the pulmonary tissue, and effusion in the cavity of the pleura may be recognized, and perfectly limited by its application. Since I indicated this method, I have had numerous opportunities of verifying its utility, nay, more, a few trials, although not in sufficient numbers to authorize a positive conclusion, lead me to hope that the application of the diapason may be useful in diagnosticating fractures of the cranium, and that its importance will not be overlooked by surgeons. Finally, M. Desprez states, that the diapason may be useful in diagnosticating the degree of deafness, but this method has long since been advantageously employed by Dr. Vidal de Cassis.

On Abrasion of the Cornea. By Dr. Malgaigne,

* *Decoctum album* is thus prepared in the Parisian hospitals—℞. Cornuum. ust. ʒij. mic. pan. alb. ʒ vj. acaciæ gumm, aquæ cinnam. aa. ʒij. syrup. simpl. ℥ij. aquæ lb. ij. Triturate the hartshorn and the bread crumb in a marble mortar, add the gum and water, boil for half an hour, strain, and finally add the syrup and cinnamon water. This preparation may advantageously replace the mistura cornu ust. of the London Pharmacopoeia.

* Vide *Gazette des Hopitaux*, No. 49, April 1843, and *Bulletin de Therapeutique*, May, 1843.

surgeon to the Hospital de St. Antoine.—Two years ago, the author addressed the details of an operation, which proved to be useful in cases of opacity of the cornea, which had resisted all other remedial measures. In this operation, one half of the cornea having been dissected, was removed, and immediately after the patient was capable of distinguishing surrounding objects. Numerous objections were made as to the final success of the operation; for instance, it was said,—that the cornea, though transparent immediately after the operation soon become opaque again; that the cornea, being much thinner, would form a staphyloma; that this membrane would never be as smooth as in its normal condition; that the rays of light broken by the numerous inequalities of its surface would produce imperfect and confused images on the retina; that even in admitting that the cornea would remain transparent, still sight would never be restored. The immediate results of the operation refuted some of these objections victoriously, but time alone could decide as to the real value of the remainder. Two years have now elapsed, and the author in the present communication shews how groundless all those objections were, and indicates this case as a physiological fact hitherto unknown, viz., the regeneration at least apparently, of the cornea. The examination of the eye reveals the existence of curious phenomena; first, the projection of the iris has completely disappeared, and evidently by its movements, the adhesions it had contracted with the cornea, no longer exist; secondly, the elevation formed around the cornea and which existed seven months after the operation, is no longer present, and the membrane is as smooth as its fellow, with the exception of a small cicatrix, situated at its upper and inner edge, and which was produced by an ulceration of the cornea caused by subsequent ophthalmia. But it may be asked, was the cornea really regenerated? Or was it, on the contrary, the elevation which was separated, so that the cornea, instead of growing thicker, had become thinner at its circumference? The former opinion, according to the author, is the more probable, but experiments on animals are necessary to remove all doubts. *En resume*, it is evident—that the cornea has not become opaque again; that it has not been distended so as to form staphyloma; that the sight is so good that the young woman can do needle-work with facility; and that, though the cornea is affected with a slight opaline tint, still she can read small print with the greatest ease.

On the Presence of Sulphur in the Bile.—Professor Liebig wrote to request M. Pelouze to inform the Academy of a very important fact in the history of secretions and principally of bile. One of his older pupils, M. Redtenbacher, now professor at Vienna, having analysed anew the *taurine* (*asparagine biliane*) of M. Gmelin, found that there was twenty-six per cent. of sulphur in this compound, one of the most remarkable in organic chemistry for the regularity of its crystals.

On the Mode in which pure Saliva acts on Fecula at the Normal Temperature of Mammiferæ, and at 167° F. by M. Lassaigne.—In this memoir the author does not purpose examining the peculiar principle which M. Mialhe states having extracted from human saliva (*diastase salivaire*), but to ascertain if pure saliva obtained by dividing the Stenonian duct acts like diastase on fecula at the normal temperature, or at 167° F, and from experiments detailed, concludes:—1° That the saliva of man and the horse at the normal temperature (100½° F) does not dissolve fecula, and that this substance is changed either in its shape or in its other physical or chemical properties;—2° That exposed to a heat of from 158° to 167° F, and kept thus for about three hours and a half, the saliva of the horse acts like water on fecula—that is to say, the grains distend and swell, but are neither transformed into *dextrine* nor *glucose*;—3° That human saliva converts fecula rapidly into *dextrine* at a temperature of from 158° to 167° F, and finally into *glucose*;—4° That during the digestion of uncooked amylaceous matter, saliva, at the normal temperature, does not possess the influence attributed to it by M. Mialhe, it contributes only—as almost all ancient and modern physiologists have announced—to moisten the food, and dissolve some of the principles soluble in the water it contains.

On the Action of the Pancreatic Juice of the Horse on Fecula. By the Same.—The experiments of the author prove that the pancreas placed in boiling water for five or six minutes, so as to be par-boiled, has no action whatever on starch at the normal temperature of the body, whereas before it was placed in the water the *pancreatic tissue dissolves* the starch at the same temperature, and changes it into dextrine. This result is obtained in one or two minutes at 100½° F. if to the par-boiled, a small quantity of raw pancreas is added.

On the Sesqui-chloruret of Chrome. Memoir read by M. Pelouze, M.A.S.—Contrary to the opinion of M. Peligot, the author states that pure sesqui-chloruret of chrome is dissolved in boiling water very slowly, it is true; the solution is obtained with greater rapidity according as the temperature is raised. He performed likewise several experiments; thus, a few grains of sesqui-chloruret previously washed in boiling water, were placed in a closed vessel, with five or six times their weight of water, and exposed for an hour in oil to a temperature of from about 302° F. to 392° F. The liquid obtained at the close of the operation was of a beautiful dark green colour, and contained a considerable proportion of chrome. With concentrated sulphuric acid, the sesqui-chloruret disengages hydrochloric acid, and a green compound is obtained, in which there is a good deal of chrome, and which is soluble in water; but, considering the length of time requisite to obtain this solution, it is probable that it is not simply dissolved but decomposed, and that the hydrochlorate of the sesqui-oxide of chrome is formed. The solution of the sesqui-chloruret of chrome by the proto-chloruret of the same metal, is not a chemical combination, but a physical phenomenon produced by a change in the disposition of their molecules. Neither the sesqui, nor any other chloruret can dissolve the violet chloruret, this being the exclusive property of the proto-chloruret. M. Loewel states, that this is because the proto-chloruret combines with a part of the chlorine; to ascertain if this were correct, the author took other compounds, which were as readily combined with chlorine, and the result was the same. The substances employed were—the proto-chloruret of tin, prepared by dissolving gr. ss. of that metal in hydrochloric acid, and the solution was sufficient to dissolve ℈j. of sesqui-chloruret—proto-chloruret of iron and copper, and the hydrosulphate of soda; in these, however, the result was not so rapid. The alcaline chlorurets, sal ammoniac, and perchloruret of tin were without any action.

On the Insolubility of the Sesqui-chloruret of Chrome, and the Sulphate of the Sesqui-oxide of Iron. By M. Ch. Barreswill, communicated by M. Pelouze, M.A.S.—According to the author, the violet sesqui-chloruret of chrome combines with the proto-chloruret to form a double salt (violet solution), which is decomposed by the water into a sesqui-chloruret (green solution), which is incapable of producing the double salt, and into a proto-chloruret, which acts anew on the violet sesqui-chloruret. In like manner, the sulphate of calcined peroxyde of iron, when dissolved in a corresponding salt of protoxyde, produces a double salt, easily decomposed by water into sulphate of peroxyde, not susceptible of forming the double salt, and into sulphate of protoxyde, which combines with a new quantity of peroxyde of iron.

On some Salts of Chrome, by M. H. Loewel, chemist, at Munster, Upper Rhine. The experiments performed by the author were—1°. In precipitating the violet-blue solution of the neutral sulphate of chrome ($Cr^2 O^3, 3SO^3$) by a solution of an excess of chloruret of barium, and filtering; sulphate of barium remains on the filter, and the blue liquid which passes through contains the hydro-chlorate of chrome $Cr^2 O^3$, 3 Cl H and the excess of chloruret of barium. This solution, when boiled, becomes green: but remains limpid, and no precipitate takes place, all the sulphuric acid contained in the salt of chrome having been previously precipitated by the chloruret of barium. 1° If the violet blue solution be boiled for a few minutes, so as to change its colour to green, and allowed to cool, a very different result is obtained: the liquid precipitated by an excess of solution of chloruret of barium and filtered, sulphate of barium remains on the filter, and the green liquid which passes through is at first limpid, but soon becomes turbid, and that even before the whole quantity is filtered; on boiling it, sulphate of barium is precipitated, and easily separated. 3° The hydro-chlorate of the neutral sesqui-oxyde of chrome is procured with difficulty from the violet-blue solution, but it is easily obtained by decomposing the violet-blue sulphate by a slight excess of chloruret of barium. If the violet-blue hydro-chlorate is decomposed by a solution of azotate of silver, and filtered, so as to separate the chloruret of silver, the violet-blue liquid which passes through contains the azotate of chrome $Cr^3 O^3$, 3Az O^5, and the excess of azotate of silver: when boiled, it remains limpid. 4°. If, on the contrary, the violet blue hydro-chlorate of chrome is boiled until it becomes green, and when cool is precipitated by an excess of azotate of silver, and the chloruret of silver separated by filtration, a green liquid is obtained, which, when boiled anew, precipitates a considerable quantity of chloruret of silver.

Academy of Medicine, Sitting of the 6th May.—M. Caventou in the chair.—The assembly was far more numerous than usual, on account of the election of a titular member in the section of anatomy and physiology, several persons who seldom, if ever, make their appearance but on similar occasions being present. The chairman read the speech he had the honour of addressing His Majesty, and the reply he received.

Election.—The list of candidates presented by the committee comprized, Drs. Longet, Manec, Baillarger, Denonvilliers, Chassaignac, and Belhomme, number of votes 110, majority 56. Dr. Longet obtained 79 suffrages; Dr. Manec 19; Dr. Baillarger 11; Drs. Chassaignac and Belhomme, each 1. Consequently Dr Longet is proclaimed a member of the academy, when his nomination is ratified by the approbation of His Majesty.

M. Henry read a report on some mineral waters, of which it was impossible to hear a syllable; the conclusions were adopted nem. con.

On the treatment of Involuntary loss of Semen by Compression, by Dr. Brachet of Lyons, corresponding member. The author after mentioning the useful work of Professor Lallemand, of Montpellier, who by his researches has rendered this disorder one of the most familiar to practitioners, proceeds to state that it is not his intention to discuss the numerous important questions raised by the learned Professor, but merely to make known the result of compression performed on the prostate gland in spermatorrhœa. The author quotes four cases produced by different causes, which were cured in the space of two or three months by pressure, and though they cannot authorize him to establish it as a general rule, still he considers them of sufficient importance to be worthy the attention of the academy, and to induce other practitioners to give it a trial. He admits however, that pressure cannot be employed indiscriminately in every case, and that often in removing the cause we cure the disease, but he thinks that it will succeed in all cases of atony, produced by venereal excesses, onanism, or blenorrhagia, if they last long and are frequently repeated. He seeks to demonstrate that the injurious effects of spermatorrhœa are owing to the loss of the seminal fluid, and that in consequence it ought to be prevented by every possible means, to the augmentation of the secretion of the prostatic fluid, which he considers similar to that secreted by the follicles of the vagina during coitus, and in some cases of leucorrhœa. As to the effects produced by compression, in his opinion they are of two kinds; in the first place it keeps the seminal fluid in its reservoirs, which are thus accustomed to its contact and enabled to retain it longer; secondly, it modifies the physiological condition of the urethra, the prostate, and excretory organs of the semen. It is thus that a cure is obtained, that is to say, by modifying the pathological state of the diseased organs, and causing them to return to their normal condition. Finally the author gives a

description of the bandage by which he exercises pressure; it is composed of a waistband in leather, the extremities of which unite on the abdomen from its centre posteriorly descends a strap which on reaching the genitals organ bifurcates, and finally is buckled in front to the preceding: it is on the latter that a small cushion is placed opposite the part on which pressure ought to be made; and he concludes by stating the advantages it presents over the other methods recommended.

On the state of Veterinary Medicine in France, by M. Hamont. In this memoir the author criticises the mode in which veterinary medicine is taught, and proposes a plan which he thinks would be productive of very beneficial results. The chairman proposed inserting the memoir in the Bulletin, which after some remarks from M.M. Barthelémy and Renault was adopted.

GARLAND DE BEAUMONT, D.M.P., B.L., & S., &c. *Honorary Physician to the Spanish Embassy.*

PROGRESS OF GERMAN MEDICAL SCIENCE.

By SIGISMUND SUTRO, M. D.

Cure of Phthisis Pulmonalis by Sugar of Lead combined with Opium and Cold Water.—The author was called upon to treat a young female, the wife of a locksmith, who was labouring under all the symptoms of advanced pulmonary consumption. The patient, who had married very young, and was pregnant soon after, had had repeated attacks of cough, pain in the chest and hæmoptysis, the consequence of great exertion in dancing. The cessation of lactation was followed by a renewal of the pain in the chest, hæmoptysis and fever, and was also attended by rapid emaciation. The respiratory murmur was weak, and accompanied with rhonchus mucosa; there were also hoarseness, expectoration, a frequent, small and rather hard pulse, the face livid, lips red, and dry; circumscribed redness of the cheeks, eyes large, skin pale, urine turbid, fæces fetid and acrid; tongue clean, appetite good. The author diagnosticated the disease as *phthisis pulmon. subflorida* near its third stage, caused by neglected chronic pneumonia. Rest both of body and mind was prescribed, besides the utmost cleanliness of the room and air, and a cool couch; cold sponging was allowed during the height of the fever. The beverage consisted of linseed tea, with lemon-juice. Her diet was six raw eggs daily, and cow's milk with stale bread. The remedies were, ℞. nitr. depur. gr. xi.. opii. gr. j. gumm. arab. gr. vj. gumm. myrrh. gr. iij. sacch. lactis. drachm. ij. Divide in part. æq. viij. one to be taken every three hours. After these medicines had been persisted in for a week, the perspiration and diarrhœa were diminished, but all the other symptoms remained unabated. The author ordered according to Wolf's recommendation: ℞. plumb. acet. gr. ½. aq. meliss. unc iv. tinct. opii. simpl. gutt. vj, syrup. unc. ½; a tablespoonful every two hours; the dose of the sugar of lead to be gradually raised to three grains. Instead of bread and milk, flour-soup was allowed. Under this treatment she soon improved. The fever and perspiration became less, respiration more quiet, expectoration free from blood, more frothy and floating on water; diarrhœa ceased; all the symptoms in fact gradually improved. Water-cresses with sour, thick cream and poppy-oil, lentils with fresh black-pudding, and raw ham agreed very well with the patient. Towards the fourth month, the patient was completely recovered, with the exception of the voice which never became perfectly clear. During that time 22 grains of sugar of lead, and 4 scruples of tinct opii. were used.—Though this plan of treatment does not cure in every case, it always affords relief. It is particularly indicated in the period of colliquation in purulent, florid consumption, and in chronic pneumonia tending to suppuration.—(*Dr. Ruppius in Hufeland's Journal.*)

The Leaves of Belladonna as a Palliative in Hæmoptysis.—About a drachm of the cut and dried leaves of belladonna is thrown on glowing coals, and the vapours inspired by the patient, when the bleeding is immediately arrested. Having seen this remedy used by a layman, the author employed it in seventeen cases of hæmoptysis, and each time with success, the vapours not being productive of any inconvenience. They rarely occasioned even a slight cough, and in two cases a feeling of peculiar ease in the chest was experienced. The inspired vapours of the saturated decoction of belladonna leaves were inefficacious, as was also the internal use of extr. belladonnæ. The smoking of belladonna leaves mixed with tobacco has been long recommended in spasmodic cough and asthma, and *Schonlein* advises the use of the leaves in hæmatemesis to diminish the great irritability of the stomach. The above experiments should be repeated, as it would be a great advantage to be able to do without venesection in such cases, as the additional loss of blood tends to favour the development of tuberculosis.—*Dr. Schröder in Osterr. Medic. Wochenschrift.*

On the Efficacy of Crystallised Nitrate of Silver in the Diarrhœa of Children.—According to Trousseau's proposal, nitrate of silver was employed in the policlinic of Berlin, by Romberg in cases of obstinate diarrhœa of children. The usual formula was: ℞. argent. nitr. crystall. gr. ½-j. solve in aq. destill. q. s. mucilag. rad. salep unc. 2½, syr. diacod. unc. ½. A teaspoonful to be taken four times a day. The author details twelve cases of acute and chronic diarrhœa in children from nine months to twelve years of age, which were treated generally with complete success; and without any subsequent injurious consequences. Even when the symptoms indicated the presence of tuberculosis intestinalis, the nitrate of silver displayed an equally good effect. The remedy does not seem to have been used at all in the form of enema.—(*Dr. Henoch in Journal fur Kinder krankheiten.*)

Intermittens Tertiana Regularis, complicated with Morbus Maculosus Werlhofii.—Amongst the many complications of intermittent fever, the morbus maculosus of Werlhoff seems to be the most rare. The patient was a strong woman of thirty-two years of age, existing in needy circumstances for some years. The regular tertian was combined with gastric irritation, when the author saw her on the 10th of June, after the fifth paroxysm. She afterwards perceived red spots on the legs, abdomen and chest, and in the night of the 18th of June some blood was discharged from the mouth, and towards the morning a greater quantity was lost by hæmoptysis. The patient became much dejected, although the febrile symptoms were lessened by means of bitters. The whole body, particularly the lower extremities, was covered with pale red, round spots. The mucous membrane of the mouth was of a pale red colour, and lax, and near the lower lip, on the right side, there was a small ulcer, whence thin dark blood oozed out; the gums were red, spongy, and inclined to bleed. Quinine, bark, acids, and ultimately, cortex salicis in decoction, with sulphuric acid, effected a cure, both of the fever and the complication, so that the patient was perfectly recovered by the middle of July.—(*Dr. Grosskopf of Waidhofen, in Osterr. medic. Wochenschrift.*)

Cyanosis.—A weakly, irritable girl, nineteen years of age, in whom the catamenia occurred early, lost them suddenly in consequence of a violent fright, and was affected with palpitations of the heart, vertigo, fainting, and convulsions. The application of a blister, and the use of anti-phlogistic treatment gave momentary relief, but the palpitation and the other symptoms soon returned; lips, nose, and cheeks became blue, the conjunctiva beset with dark blue veins, the nails of hands and feet livid. Powerful antiphlogistic remedies did not afford any relief. The author, who was afterwards consulted, found, besides the above symptoms, strong pulsation of the abdominal vessels, hysterical spasms, offensive perspiration, and great fear of death, as also violent pulsations of the heart and large vessels, the chief veins much engorged, and the pulse quick and frequent. The author considered the arrest of the catamenia as the primary cause of her complaint, and ordered her to be cupped on the inside of the thighs, and over the sacrum; poultices on the abdomen, baths, with nitric acid, and large doses of aloes dissolved in aq. laurocerasi, internally, besides castor and crocus. The spasmodic symptoms were soon removed, but the menstruation not being restored, tinct. chenopod., valerian, aloes, and saffron, were ordered internally, besides baths, and friction of the upper part of the thighs, by which means the menstruation returned, and the cyanotic symptoms were removed. The hysterical affection was also cured. In conclusion, the author observes that the functions of the heart may be disturbed without any organic changes, every derangement of a distant organ occasioning sympathetic morbid symptoms. The natural tone of the blood-vessels being weakened at one place, they are over, charged at another, and thus the equilibrium between the pressure of the blood and resistance of the vessels is disturbed.—(*Dr. Teitteles, of Prague; Ibidem.*)

Eneuresis Paralytica.—With two women the pressure of the child's head on the bladder was the decided cause of a paralytic state of the muscular sphincter vesicæ. Acting on this opinion, the author cured the eneuresis in a few days, by administering pulv. secal. cornut. (gr. iv.) with pulv. canthar. (gr. 1-6th), one powder to be taken every three hours, besides external frictions with tinct. canthar. and mist. oleos. balsam. In the case of an old man, who had been formerly affected with hemorrhoids, and in whom the eneuresis was produced by sudden cold, abstraction of blood, and the anti-hemorrhoidal treatment was of no use, so that the author ordered—℞. Decoct. secal. cornut. (ex drachm ½), unc. iv. inf. herb. bellad. (ex scrup. i.) unc. ii. acid. phosphor. drachm. ii. extr. nuc. vomic. gr. v. syr. mann. unc. i.:—a tablespoonful to be taken every two hours. In all these cases the disease rapidly improved, so that, after a few days, the following was ordered—℞. Extr. bellad. gr. iv. extr. nuc. vom. gr. vi. acid. phosphor. drachm. fifteen drops to be taken three times a day. A tonic, with aromatics, completed the cure. —(*Dr. Steinbeck in Casper's Wochenschrift.*)

Cure of Diabetes.—S., at B., a labourer, ætat. forty six, formerly strong and healthy, has complained, since the summer of 1838, of fatigue, and constant perspiration during work. Digestion disordered; acid retching; disagreeable sensation at the pit of the stomach; great quantities of urine passed, particularly during the night, and great thirst. Appearance of the patient cachectic. The urine, which was of a greyish yellow colour, and sweetish taste, was evaporated one half; the abundant honey-like sediment was further treated according to Frank's method, till it assumed the colour, taste, and purity of sugar. The author thus obtained six drachms of sugar from about six ounces of urine. The other half of the urine was preserved, together with healthy urine, and became acid, depositing a white flaky substance, whilst the healthy urine became putrid. The diagnosis was thus made clear. The author therefore ordered animal diet, and the use of Peruvian balsam, in the dose of from forty to fifty drops, to be taken from three to four times a day. The patient soon improved, and the medicine was given, in gradually increasing doses. After three weeks the thirst was removed, urine was only discharged once a night, and in another fortnight he completely recovered. His complexion is now as healthy as it was previously cachectic, and the urine presents the usual normal properties.—(*Dr. Van Nesin Mingn, Hannover. Annalen.*)

Helminthiasis.—The following observation shows how many worms the human body may contain without considerable reaction. A girl, ætat. fourteen, who neither felt ill, nor displayed any objective signs of ill health, was seized, on the 22nd of August, 1839, with violent vomiting, discharging several ascarides lumbricoides. On the 23rd she discharged twenty-five worms by vomiting. Whatever she took occasioned sickness. Purgatives afforded no relief. The abdomen was hard and tense in parts, and she complained of occasional violent lancinating pains. On the 30th, in consequence of powerful enemata and internal remedies, she had several stools, containing thirteen worms. After taking inf. senn. and cinn. cum extr. cin. æther. the next day, a great quantity of worms were passed, per anum, without fæces, altogether about 184. Worms being discharged daily, the infusion of senna and cinnamon was continued for a fortnight, and by that means great quantities

of worms were got rid of, amounting, within seventeen days, to the number of 808. Generous diet, and preparations of steel, soon restored the patient to her former health, and she has not had a relapse since.—(*Dr. Volz, in Heidelberg. Annalen.*)

PROGRESS OF ENGLISH, ITALIAN, AND AMERICAN MEDICAL SCIENCE.

CHARACTERS OF THE HAND-WRITING.—In an anonymous communication, published in the *Northern Journal of Medicine*, under the title of—"Account of the Alleged Art of Reading the Characters of Individuals in their Hand-writing;" it is stated that the physiology of handwriting lies in its connexion with Temperament.—When the hand is small, close, without freedom or fluency, the hair and eyes are almost always black, or very dark, the complexion pale or cream-coloured, or if the hair be lighter, the person is spare and dry, the complexion brown or sallow, free from colour. Not unfrequently very black-haired persons write a different kind of hand, in which case they are commonly florid, or at least of fuller habit. Sir Walter Scott's autograph is almost an exception, for, notwithstanding his fair complexion, it approaches closely to the hand of the dark-haired. In this case, the small and confined turn of the hand may have been the result of that delicacy of health under which he suffered in early life. This is a kind of case in which an error cannot be avoided without precaution. But the adept is ever on his guard, and strives to shun such errors by making cautious approaches by means of indirect questions, and his wariness is commonly rewarded by the timely disclosure of the hazard to which his art would have been exposed by a too rash application of its rules.—When the hand is large, free, and flowing, or large, straggling, and irregular, it may be generally pronounced that of a fair-haired person.—The two opposite kinds of handwriting belong to different kinds of temperament, for these opposite complexions mark different temperaments. And as certain mental characteristics, not indeed of a particular but of a general kind, on physiological grounds, can be assigned to the several temperaments, a foundation is thus obtained for the discovery of some points in the mental habits of the individuals under examination, which, with a little skill, may be dressed up into a plausible account of their prevailing modes of thought and action.

THE UTERUS OF THE MARSUPIATA.—The uterus of the marsupiata is very peculiar, and exhibits in the several genera varieties which, however, are not very remarkable, so that its structure in the kangaroo may serve as an example. The oviducts are at their abdominal extremity surrounded with a folded crown of fimbriæ, and each, very delicate at its commencement, expands into an elongated uterus, in which the small embryos are developed, and attached by a short umbilical cord. Both uteri open into the vagina, which is likewise double, and very peculiarly formed, as it frequently forms a cæcal sac, which is often divided by a septum, into the commencement of which the uteri open. From this arise superiorly the vaginal canals, two handle-shaped and intestiniform membranous tubes, frequently contorted, which coalesce in front of the external sexual opening, or kind of cloaca. Through these the small and still imperfectly developed fœtus unquestionably reaches the exterior, and is conveyed by a process not yet known into the pouch.

COLON STRANGULATED BY THE MESO-COLON.—Dr. Gilman Davis, of Portland, Maine, relates, in the *Boston Medical and Surgical Journal*, an interesting case in which fatal strangulation of the colon occurred in an aperture in the meso-colon. The patient was a gentleman, twenty-six years of age, who was attacked on the 18th October 1843 with paroxysms of pain in the epigastric region, without tenderness; but with remarkable tonic rigidity of the abdominal muscles, and constipation. By the use of cathartics, enemata, and opiates, after three days' suffering, evacuations were produced from the bowels, and the other symptoms then yielded. He then enjoyed moderate health after this until the 5th May 1844, when he experienced another attack similar to the first. There was superadded to the previous symptoms constant vomiting; every thing swallowed was instantly rejected. There was no thirst; the firmest pressure on the abdomen caused no pain; there were extreme restlessness and nervous agitation, and he complained that there was a stoppage in the epigastric region, and said he should feel better if he could only have an evacuation from his bowels. Various remedies were employed, but he got worse and worse, and died at midday, May 9th. On the *post-mortem* examination a large knuckle of intestine, of a deep port wine colour, composed of thirteen inches of the colon, was found strangulated in an aperture about the size of a shilling in the meso-colon. From the strangulated intestine to its termination in the anus measured four feet. It was in a complete state of mortification. The aperture was rounded with even edges. No reasonable conjecture could be formed as to the cause of its formation.

EVULSION OF THE LEFT ARM AND SCAPULA.—Dr. King narrated the particulars of the following case at a meeting of the Medico-Chirurgical Society of Edinburgh. The patient was a stout boy aged fifteen, whose left arm got entangled between the wheels of a grain mill, and was torn completely off. He fainted immediately after the accident, but soon recovered sufficiently to be carried home, a distance of half a mile. No blood flowed from the wound at the time, and the whole quantity lost did not exceed two tea-cupsful. The wound left by the accident extended from an inch from the sternal extremity of the clavicle to the right side of the upper portion of the dorsal vertebræ posteriorly. The axillary artery projected two inches and a half from the wound, and pulsated strongly to within an inch of the orifice, but gave exit to no blood. Its external coat was divided into three irregular pieces, which encircled each other, and held a small coagulum in their embrace. The artery was secured by a ligature, and the ragged edges of the wound approximated by adhesive plaster. Very trifling reaction followed, the wound granulated kindly, except a portion of the skin, and the mass of the end of the nerves, which sloughed. Touching the latter caused great terror to the patient. The recovery was complete in about six weeks.

EXTERNAL RUPTURE OF THE STOMACH.—Dr. Watson informed the Medico-Chirurgical Society of Edinburgh, of the case of a young woman, a patient of a friend of his in the country, who had an aperture from the stomach externally. After having severe dyspeptic symptoms for two years, this opening burst externally four months ago, and continued to give exit to fluid and solid food after eating. It was gradually contracting, and the patient was apparently getting well.

FRICTION VIBRATIONS IN PERITONITIS.—Dr. Spittal at a meeting of the Medico-Chirurgical Society of Edinburgh read some observations on the mechanism and diagnostic value of the friction vibrations perceived by the ear and by the touch in peritonitis. The following were the principal conclusions at which he arrived:—That the mechanism by which the fricton vibrations are produced are of three kinds, viz. *1st.* By the respiratory movements of the diaphragm chiefly; but also by the action of the abdominal muscles; the vibrations being synchronous with these movements, though sometimes only perceived during inspiration. *2nd.* By artifical movement of the parts by pressure with the hand or otherwise; the vibrations corresponding to the movements produced. *3rd.* By the peristaltic motion of the intestinal tube; the friction having a peculiar continuing, rustling, creeping character to the ear and the hand, corresponding to the vermicular motion of the intestines. That the immediate cause of the vibration is the rubbing together of two peritoneal surfaces physically altered by inflammation, and although the effusion of lymph has been considered necessary for their production, it appears highly probable that at a prior stage of the disease, when the peritoneum is merely drier than usual, friction vibration may take place. That the amount of motion between the inflamed surfaces, necessary for the production of the friction vibration, is very limited; and that the different modes of friction as to *rapidity* and degrees of *pressure*, may not only modify the intensity, but also the tone and quality of the vibrations. That the present state of our knowledge does not permit us to connect any particular species of vibration with a certain physical condition of the serous surfaces, although reasonable grounds exist for this expectation. That although the friction vibration cannot be required as evidence of the existence of adhesion between the peritoneal surfaces, it has not been proved that, in the case of partial adhesion, and even when the adhesions are general, provided the effused lymph be recent, soft, and extensible, an amount of motion sufficient to produce friction vibrations may not occur. That the respiratory abdominal friction vibrations are chiefly manifested at the upper part of the abdominal cavity, where the more solid contents are situated, and in the case of a large organic tumour, and may be regarded as indicative of the inflammation having its site over a solid organ or tumour. That the indications from artificial movements of the parts have been perceived, both over solid organs or tumours, and over the intestines. That the *peristaltic* friction vibrations indicate with *certainty* that the peritoneum investing the corresponding portion of the intestinal tube is the part effected; and that wherever these peculiar vibrations are very distinctly perceived, they may be regarded as indicative of a lively and free motion of the folds of intestine upon one another and upon the parietes, or that no adhesions exist between them; at all events, that they are not generally adherent, nor matted together into an adherent mass, nor to any great extent adherent to the abdominal parietes.

ENLARGED HEART.—Dr. Shearman at a meeting of the Sheffield Medical Society presented an enlarged heart, which weighed fifteen ounces and a half. The auricles were greatly dilated; the right auriculo-ventricular opening was larger than natural, and the left was so contracted as only to admit the tip of the little finger. The pericardium was partially adherent to the heart, and contained a considerable quantity of fluid. The patient was a female, aged fifty-two, of remarkably small stature, and was first seen by Dr. Shearman, in the year 1838, when she was suffering from a severe attack of pleuritis, which terminated by fluid effusion. He did not see her again till two months before her death, when she was suffering from severe dyspnœa. The whole of the right side of the chest, which was the seat of the former pleurisy, was solid, and immovable, and measured three inches and a half less in circumference than the left. There was great jugular pulsation; a murmur was heard with both sounds of the heart at the third rib, over the sternum, and also at the bottom of the sternum, and about an inch and a half to the axillary side of the left nipple, in which situation the apex of the heart was observed to pulsate. The right lung was found, on the *post-mortem* examination, to be condensed and compressed into a small space at the top of the chest, and the pleura closely adherent.

DISEASE OF THE BLADDER; GRANDULAR KIDNEYS.—Mr. Law at a meeting of the Sheffield Medical Society, exhibited the bladder and urethra of a man, aged 64, who died in a state of coma, three days after admission into the Infirmary, on account of urinary disease. Great hypertrophy of the bladder existed, and it was partially sacculated; a tumour of about the size and shape of a hazel nut, was found over the verumontanum, having a broad base, and being of a fibrous structure; the kidneys exhibited granular disease, and the ureters were considerably dilated; emphysema at the edges of the lungs, and there was slight opacity of the arachnoid. For seven years he had laboured under some urinary obstruction, presenting some of the symptoms of stone, but there was nothing of the kind detected on passing the sound. No anasarca, nor any circumstance which led to the suspicion of the existence of Bright's disease, during life; but the urine removed from the bladder after death readily coagulated. Coma came on about eight hours previously to death.

SYPHILITIC ULCERATIONS OF THE CERVIX UTERI.—Dr. Henry Bennett says that the real classical chancre, presenting its ordinary physical characters, is excessively rare on the cervix uteri. Ulcerations presenting the characters of the inflammatory ulceration are, on the contrary, exceedingly common in patients labouring under blenorrhagia, or primary, secondary, or tertiary

syphilis. Some few of these ulcerations may be primary or secondary, but the very great majority are merely inflammatory.

PUERPERAL FEVER.—Mr. Storrs, of Doncaster, read a paper at a meeting of the Sheffield Medical Society, "on the contagious effects of puerperal fever on the male subject, or on persons not child-bearing;" in the course of which he laid down the following proposition:—That puerperal fever is capable of imparting to any person not in the puerperal state, by actual contact, or close approximation, the following diseases. I. Inflammation of the peritoneum or other serous membranes, accompanied by low fever, both in the male and female subject. II. Erysipelas, either local, as in the hand or arm from *post-mortem* inspections; or general, as in the face or person. III. Typhus fever, with its various accompaniments, and in a variety of forms.

EXTRACTS OF CANNABIS INDICA.—Dr. Inglis has examined two extracts of this plant, one pure, and the other much adulterated. He thus describes their essential properties. In spring water:—pure extract wholly insoluble and immiscible. Spurious extract partially soluble and quite miscible; a dirty green sediment separates on standing; supernatant fluid, amber coloured.—In a solution of caustic ammonia: pure extract almost insoluble; the ammonia acquires a light yellowish green tinge, which, when neutralized with acetic acid, deposits a brownish green precipitate; the extract left is imperceptibly altered in weight, becomes softer, and assumes a paler green colour than before. Spurious extract almost wholly soluble; solution of a dark, dirty brown colour; a small green insoluble residuum is left on the filter, which is the portion of pure extract present in the specimen.—In a solution of caustic potass: pure extract almost insoluble; tinges the liquor potassæ of a light brown amber colour, which, when filtered and neutralized with acetic acid, deposits the colouring matter in light green flakes; the insoluble extract remains unaltered, retaining its fresh bright green colour. Spurious extract almost wholly soluble; solution of a dark reddish brown colour, a brighter brown than with the ammonia; the potassa brings out a strong decided flavour of green tea, which completely overcomes that of the small quantity of gunjah present.—In alcohol: pure extract entirely soluble; solution—bright grass green, which deposits on standing, a precipitate of light green colouring matter; when dropped into water, the tincture deposits its extract, and gives to the water a milky opacity, having also the green tinge of the gunjah; this is again rendered transparent by liquor potassæ, and re-rendered opaque by excess of acetic acid. Spurious extract partly soluble; solution—dirty green, precipitates on standing, a large granular deposit of brown and green matter; this tincture when dropped into water, gives it a brownish green tint, not milky, which, on addition of liquor potassæ, becomes amber-coloured.—In dilute spirit: pure extract insoluble. Spurious extract almost wholly soluble; solution—deep, dirty brown, which deposits a large brownish green sediment; liquor potassæ added, brings out the strong flavour of tea.—In strong acetic acid: pure extract insoluble; the extract becomes of a lighter green colour; the acetic acid remains colourless. Spurious extract almost wholly soluble; solution—dirty green; precipitates a green deposit, which seems to be the small portion of gunjah present in the spurious extract.—In wood naphtha: pure extract entirely soluble; solution—fresh, bright, emerald green; very little deposition of green colouring matter. Spurious extract almost wholly soluble; solution—olive brown, throwing down, on standing, a mixture of brown and green precipitates.

GANGRENOUS INFLAMMATION OF THE MUSCLES.—Dr. Blackmore in the *Provincial Medical Journal*, describes several cases of gangrenous inflammation of the muscles, some of which terminated fatally. The first was that of a man of industrious and sober habits, aged forty-five, of a robust and muscular frame, who had been hard at work plastering the ceiling of a room, which made his arms ache severely; after which he was attacked in the afternoon of August 12th, 1831, with severe rigor, sickness, and pain in the middle of his arms and calves of the legs. The pain continued unmitigated, and in the evening of the next day, as he manifested a tendency to stupor, he was bled. On the third day he complained of headache, the pain in the limbs was less severe, but he had much pain in the belly, and vomited. On the evening of the fourth he was still suffering in the belly and limbs, without much fever. On losing a pound of blood he fainted; the blood buffed, not cupped. Twelve leeches were then applied to the abdomen, ten grains of calomel, with some Dover's powder, a saline purgative, and colchicum. The morning after, his manner expressed alarm and restlessness; breathing hurried; tongue loaded; urine high coloured; the bowels had been purged; the abdomen bore pressure well; each arm at the middle of the biceps was tumid, livid, and very tender; gangrene had manifestly begun: the pulse had ceased at the wrist. He died in an hour. Inspection twenty hours after death. The body presented externally the appearance of health, except at the arms, which were black and vesicated; an extravasation of bloody serum, in the subcutaneous cellular texture around the bicipites muscles; sanious matter flowed from the orifice in the vein, the exterior of which was livid, but did not appear diseased. The substance of the bicipites was gangrenous; the legs were similar to the arms. On opening the chest fœtid air escaped; the right lung was a little turgid with dark blood; the heart pallid and collapsed; the peritoneal coat of the small intestines showed a diffuse livid vascularity; they contained fœtid air; the other viscera were sound. The second case was that of a labourer, aged sixty, who was attacked with rigors and severe pain in his limbs and body generally, followed by headache. On the third day he had the most agonising pain in the middle of the anterior part of the right thigh, which quickly became tumid and tender. At five p.m. he was bled to eight ounces, and twenty leeches were applied on the thigh; after which ten grains of calomel with opium were given; the pain was rather mitigated. The next morning the pain at the thigh was so severe, in paroxysms as to induce syncope; in the remissions the pulse was natural; the tongue whitish; thirst intense; no pyrexia; headache gone; the thigh was scarified to relieve tension; the usual quantity of blood did not flow on the incision; a poultice was then applied, and purgatives given. The next day, at one p.m., he was pulseless; the respiration hurried; the mind collected; the sartorius, which the incision had exposed, was gangrenous. Cordials and opium were given; but he died in a few hours. The third case was that of a poor woman residing near the last patient, in whom gangrenous inflammation of the pectoral muscle was followed by extensive, unhealthy suppuration, and ultimate, but slow recovery. The fourth case was that of a labourer in the lime-stone quarries, who died from gangrenous inflammation of the muscles, about the right shoulder, neck, and also about the sacrum. The following were the *post-mortem* appearances:—Among the muscles around the shoulder joint, an infiltration of two pounds of unhealthy pus; an abscess among the pectoral muscles; in the pleura much turbid bloody serum; the lungs hepatised and tuberculated at the upper part; the tubercles hard; in the pericardium a large quantity of serum; the heart small and flaccid; the liver hepatised and tuberculated, of a nutmeg appearance; the small intestines, externally, much inflamed; their interior not examined, as the body was very fœtid. Other cases of this peculiar inflammation were met with at this time by other practitioners. A case, similar to case one occurred at the same time to a medical friend at Plymouth; and in the same month an experienced surgeon in the neighbourhood met with a fatal case, which caused great consternation. The patient had had the influenza shortly before, and after it complained of severe pain in the legs; in a day or two, when thought to be recovering, he died unexpectedly. The legs had become gangrenous in twenty-four hours. In the middle of the autumn, similar cases occurred at Launceston, in Cornwall, thirty miles north-west of Plymouth, and excited great alarm by their novel and extraordinary character. The wife of a respectable tradesman was attacked in the evening with severe pain in the wrists; the next morning the parts were gangrenous; and she died. Dr. Blackmore adds scarlet fever and influenza also prevailed in the same season, and were fatal in some cases from malignant inflammation in various parts of the alimentary canal. He remarks that it is obvious that this singular affection was not a pure inflammation; its primary element was constitutional; its origin atmospheric. He conceives it to be analogous to the plague, and to erysipelas, which Sauvages rightly placed among the exanthemata, and Cullen after him, although doubtingly.

PUERPERAL FEVER.—Dr. Blackmore, in the *Provincial Medical Journal*, mentions the case of a woman subject to dyspepsia, who was attacked by puerperal fever, of which she died. On examining the body two pounds of puriform serum, containing albuminous flakes, were found in the abdomen. The parietal peritoneum at the iliac region (the chief seat of pain), and at the hypogastrium, was very vascular; the uterus healthy; the stomach distended with air and fluids, its texture very lacerable, and at the cardiac end very livid, from extreme vascularity in the peritoneal and muscular coats; the mucous coat healthy. Of the small intestines also, the peritoneal coat was vascular; the mucous natural. Here the stomach was the seat of the more intense inflammation, the foundation of which had been laid in the previous dyspepsia.

POISONING BY PRUSSIC ACID.—An interesting case of poisoning by prussic acid, which occurred at Warkworth, is noticed in the *Gateshead Observer*. The deceased, Jane Hume, aged 17, was servant to Mr. Turner, of Warkworth, Northumberland, chemist and druggist. Early on Tuesday morning, the 29th ult., (only a few minutes, indeed, past midnight,) Mrs. Turner, while passing to her bed-room, heard a *moan* from the room of her maid, and, pushing open the door, saw her *struggling, apparently in great agony, and insensible*. A candle was burning by her bedside, and she was fully dressed, except that her shoes were off. Mrs. Turner alarmed her husband, who quickly brought Mr. Leithead, a surgeon, to the house, who found her still breathing, but pulseless. She breathed thrice after his arrival. Mr. Leithead thought he perceived the odour of prussic acid. On the following day an inquest was held. The jury proceeded from the Sun inn to view the body; and Messrs. Leithead and Gibson, surgeons, immediately on entering the room, were struck by the peculiar smell of prussic acid. A quantity of liquid had exuded from the mouth and nostrils, which smelt strongly of the poison. The search for a phial was therefore resumed, and more narrowly prosecuted. The body was removed from the bed, and the bed from the mattress, on which, about the centre, was lying an ounce bottle, labelled "Hydrocyanic Acid, Scheele's, Spec. Grav. 995," &c., only eight drops remaining in the phial. It appeared, from the evidence given before the coroner, that the girl had great opportunities for obtaining the poison, it being kept in an easily accessible cork-drawer. The jury did *not* reprimand her master for his carelessness. The girl's motive appears to have been a disappointment in love. She was not pregnant. The medical men were of opinion, on examination, that her death was occasioned by prussic acid. It was also their belief that she had herself placed the phial between the bed and the mattress. No scream or shriek was heard by Mr. or Mrs. Turner, or by any other person, at the time of the suicide. The verdict of the jury was, that "the deceased took a quantity of prussic acid, a violent poison, being at the time in a state of temporary derangement." The editor of the *Gateshead Observer*, in commenting on this case, observes that, "Recent cases of poisoning—and especially that of Mrs. Belaney—had no doubt familiarized the girl's mind with the name and nature of prussic acid; and that tempting fiend, opportunity, placing the deadly drug, day after day, at her command, she fell a victim to our fatally-defective laws. One of our most powerful poisons is kept in a cork drawer! under the

guardianship of a lad not yet in his teens ! ! and accessible to a lovesick girl of seventeen summers ! ! ! What wonder that suicide was the consummation? and how many further sacrifices must we have before our lawmakers will regulate the sale of poisonous preparations?"

FUNGOID TUMOUR OF THE CEREBELLUM: AMAUROSIS.—Mr. Simmons, at a meeting of the Birmingham Pathological Society, exhibited the optic tract of a man, who had suffered for two years from amaurosis. He died suddenly, and there was found a large fungoid mass in the cerebellum. He was a man forty-five years old, a porter on the London and Birmingham Railway, of rather full habit of body. About two years back, when on duty, he was taken with pain and giddiness; this was repeated two or three times, for which he was bled, purged, &c.; amaurosis afterwards ensued; after which, he principally complained of pain in the back of his head; the eyes were bright, quite insensible to light; he was very morose and dull in his disposition, but was easily excited, and became very passionate. There was slight imperfection in walking. He went on thus without any material alteration until about four months before his death; when one morning Mr. Simmons observed the right eye very much inflamed, and the cornea ulcerated; there was no discharge; no sensibility to light; and so little pain, that neither he nor his friends were aware of it. This was removed by appropriate treatment; but the pain in the head became more and more severe, and scarcely any position seemed to relieve it. He died shortly after. On examining the body after death, the membranes of the brain were healthy, the substance quite firm; the left ventricle contained fully half a pint of clear colourless fluid, the right about four ounces; the substance of the brain was so firm that the finger was moved about in the ventricles freely, without injuring the septum lucidum; corpora striata and optic thalami, healthy; most of the base presented a degree of softening, the more decided by comparison with the consistency of the remainder of the brain; this condition affected more particularly the surface of the crura. The pons and medulla oblongata had quite lost their consistency. The cerebellum was very large. It contained a fungus as large as an orange, which occupied the left and a part of the right lobe. It grew from the back part of the organ, where it was attached by an extensive base, and projected into a cavity within the cerebellum, occupying the place of the natural nervous tissue. The remaining substance of the organ, which enclosed this cavity in front and on the left side, was about half-an-inch thick, and quite healthy. The inner surface of the cavity, and the surface of the fungus, were thickly coated with a matter, which had much the appearance of inspissated mucus, though rather less tenacious. The texture of the fungus was somewhat softer than the natural condition of brain; it seemed to be composed of altered cerebral substance.

CARCINOMA OF THE RECTUM.—Dr. Fletcher at a meeting of the Birmingham Pathological Society, exhibited a specimen of carcinoma of the rectum, which was ulcerated to a great extent, accompanied with an enlarged prostate, the bladder much thickened in its coats, and containing thick turbid urine of a very ammoniacal smell, as also about two hundred of very small round calculi, most of them about the size of mustard seeds, and some about three times as large, composed principally of lithate of ammonia.—It was taken from the body of Richard Fouch, who was admitted a patient at the General Dispensary, under the care of Dr. Fletcher, December 7th, 1843, with a hard scirrhous tumour at the posterior and right side of the rectum, pressing upon the bowel, and very much diminishing its calibre. Laxatives and opiates afforded transient relief, but in the course of three months he began to pass blood and pus with his motions, and suffered severe scalding pains on passing them. An examination was then made, by which ulceration of the tumour was detected, which in the course of two months more was so far advanced as to have produced a cavity capable of containing the fist. Amussat's operation for making an artificial anus in the descending colon was now recommended; but to this the patient would not consent.—The enlargement of the prostate next produced mischief, arresting the excretion of urine, and on two occasions coma supervened. On examination of the body after death the organs of the chest and abdomen were found in a very healthy state; the whole of the morbid changes lay in the rectum, prostate, and bladder, which have already been described, and in the ureters and pelvis of the kidneys, which were considerably dilated.

REVIEWS.

A Treatise on Corns, Bunions, the Diseases of the Nails, and the General Management of the Feet, by LEWIS DURLACHER, Surgeon Chiropodist to the Queen. London: Simpkin, Marshall, & Co. 1845.

WITH the exception of a few scattered and brief notices in works on general surgery, and diseases of the skin, the subjects treated of by Mr. Durlacher have been left so many *tabulæ rasæ*. There is indeed the work of Lyon, entitled "On Spinæ Pedum," but it is not only out of date, but totally unsuited to the present state of knowledge; and we should not overlook a book published in 1818, "On the Management of the Feet," which certainly contained a large amount of information, conveyed in a clear and intelligible manner, but a great part thereof was transcribed, with a few alterations, from Lyon's work.

The commencing chapter of the work is dedicated to the consideration of the cause and growth of corns; the former being referred entirely to the effects of undue pressure and friction, by which irritation is set up in the part, an increased quantity of the epidermis is secreted by the irritated papillæ, and bulbs or projections are formed, generally of a conical shape, and are protected by effused lymph, which forms a sheath or sac around them. The rapid reproduction of the corn after its extraction in chronic cases, is owing to the existence of this sac, which is soon refilled with epidermic secretion, and this becomes a corn, from the continuance of the exciting cause. Corns are classed under the following heads: hard, callosities, soft, festered, and neuro-vascular. These may be situated on all the prominent parts of the toes or feet, and admit of different kinds of treatment, according to their position, and the degree of attendant inflammation. Separate chapters are devoted to the consideration of each of these different kinds of corns, in their respective situations, and their appropriate treatment is clearly and distinctly pointed out, and illustrated by the detail of cases.

The neuro-vascular corn, which it appears was first described by Mr. Durlacher, is met with in persons of fair complexion, with very fine and moist skins.

> When fully developed, the epidermis covering the affected part is slightly thickened and transparent, having villi or nervous fibrillæ clearly visible, running in zigzag whitish lines within the induration, and small corns appearing between them like white specks, corresponding in form to the cells or follicles they occupy.
>
> Although these corns are as insensible as any other cuticular thickening, the intermingled nervous filaments are so exceedingly sensitive to pressure, that the softest leather of any shoe can scarcely be borne, and the least touch in attempting to remove any part by an operation, gives the most excruciating pain.

This is the variety of corn, according to Mr. Durlacher, which, when unskilfully or improperly treated, particularly in aged persons, has been productive of very serious consequences, and even, in some instances, of death, from the resulting mortification.

> The first treatment should be by palliative remedies, particularly during the inflammatory state; the application of lint dipped in cold water, covered with oiled silk, will generally be found sufficient for the purpose, together with rest, directions being given to avoid all pressure.
>
> When the irritation has ceased, the thickened cuticle may be carefully removed without giving much pain, if the nervous fibrillæ are not touched by the instrument, after which soap plaster may be applied, at the same time guarding the projecting joint from the pressure of the shoe by mechanical means.
>
> In the chronic form, which is always unattended with inflammation, but where the epidermis is much thickened, it should be scraped off, until the while lines and intermediate specks are visible. The corns should then be very carefully picked out from between the filaments, great care being taken in the operation to avoid pricking them or producing hæmorrhage, as it would be attended with excruciating pain, and might cause great irritation and inflammation; the wetted lint should be afterwards applied for a few days, or until the soreness and pain cease, and then a small piece of cerate plaster should be placed over the corn, and worn continually.
>
> With the usual caution against pressure, perfect relief will thus be obtained.
>
> When the corn has existed for any length of time, and pain is only produced by pressure, the same treatment must be followed, and nitrate of silver lightly rubbed on the part after the small corns have been extracted. The application should be repeated from time to time, as much of the cauterised skin being first scraped off as possible, previously to its being reapplied.

The vascular excrescence which is treated of in the seventh chapter, appears to be of the nature of aneurism by anastomosis. It is thus described:—

> This disease is a deep-seated spongy or vascular substance, forming a circumscribed tumour, not projecting much beyond the level of the thickened cuticle; when fully developed, the whole of the surface is studded with red and black specks, and the surrounding integuments are inflamed and swollen.
>
> In some cases the minute extravasations are not distinctly defined; the excrescence then appears as a softened tuft, the vascular fibres composing which seem to be of unequal length. When an attempt at extirpation is made with the knife, hæmorrhage to a considerable extent immediately follows, all the minute vessels pouring forth their contents very profusely.

The treatment consists in superficial incision of the diseased surface, and cauterizing it with nitrate of silver, repeating the operation until a cure is effected. As long as any oozing of blood follows the removal of the part which has been acted on by caustic, even if it occur only in isolated points, those parts must be re-subjected to the action of the caustic. The chapter on bunions is of great importance, but from its exceeding length, we must refer our readers to the work itself, which they will find well worth their perusal.

The succeeding chapter is devoted to the consideration of the nails, and their diseases, and is illustrated by two lithographs, the latter of which appears to us to be too highly coloured. The various diseases to which the nails are subject, are very carefully considered, their symptoms described, and the treatment well pointed out.

> The most formidable disease connected with the toe nail is that which is called "the nail growing into the flesh." It is met with most frequently in the great toe, but all the other toes are liable to the same complaint, but less severely. It is caused by an improper manner of cutting the nails, or by the flap of flesh being forced up against the edge of the nail, from wearing shoes too narrow, or from the edge of the nail being curved, or taking some other vicious direction.
>
> Persons, when they first feel pain in the sides of the toe, are apt to regard it as caused by th

nail having been allowed to grow to too great a length, and accordingly commence cutting it, thence deriving temporary relief. In consequence of the pressure of the shoe, which is still continued, the flap is forced more against the remaining rough edge in walking than before, and there is consequently more pain and uneasiness experienced, but lower down, nearer the matrix. The flap thickens, is pushed upwards still further, and partially covers the nail, which, as the pain continues, is again and again cut, until the scissors can no longer reach the part which is supposed to cause the suffering. The consequence is that a point is left which penetrates the flesh, keeps up and increases the previously-existing irritation, produces severe pain and ulceration, and, if neglected, fungus sprouts from the part most affected.

In other cases the nail forms such a decided curve under the flap, that its edge, along the whole length of the toe, is imbedded in the soft parts, which become inflamed and so much swollen, that not above one half of the nail can be seen. Walking will increase the inflammation, and ulceration will take place in the whole length of the furrow. Under improper treatment or neglect, this state will continue with many persons for months, until the whole is covered with fungus, or what is denominated proud flesh. The pain will then be so severe, that the weight of the body cannot be sustained upon the toe, and the patient is compelled to rest the limb.

In the more severe cases, those, for instance, which are known by the name of Onychia Maligna, the ulceration extends round to the soft parts at the root of the nail, which become swollen and inflamed, of a deep red or purple colour; and a thin ichorous discharge, possessing an offensive odour, is secreted. The ulceration presents a very unhealthy appearance, and after a time the secreting glands become involved; the nail is consequently loosened, and even partially detached.

Mr. Durlacher has described a very important operation for the cure of this disease, in the following terms:—

The operation which I have practised for many years consists in the dissection of the horny structure of the nail from the epidermis to which it adheres. I commence by firmly laying hold of the lateral and under parts of the ball of the toe with the thumb and fore finger of the left hand, so as to draw the flap away from the nail; I then pass a steel probe, made for the purpose, between them, and round the epidermis at the root, so as to loosen the skin from its adhesion to the nail; then, with an instrument made similar to a cataract knife, but much thicker and shorter, I dissect the piece of nail from the skin by small incisions following each other. This part of the operation must be done very carefully and slowly, beginning at the top of the nail beyond the point that is imbedded in the ulceration, the edge of the instrument being inclined outwards. As soon as the part can be laid hold of with a pair of sliding forceps, it should be enclosed, held firmly with the thumb and finger, and then turned gently outwards, in order that the dissection may be carried on to the semilunar fold; the piece may then be pulled out, but if it should adhere to the skin, the knife must again be used to detach it. If the skin is loose and rises with the nail, it may be cut off. In many cases this operation can be performed without inducing hæmorrhage, and if the disease has existed for any length of time, the nail will be more easily removed, as the ulceration will have destroyed the soft parts to which it adheres, and the nail is much sooner separated

The after treatment consists simply in the application of caustic until the fungus is destroyed, and of lint, wetted with cold water, round the parts. The relief is so instantaneous, that the patient can always walk about immediately after the operation.

Other operative proceedings have been adopted, especially those by Dupuytren, Sir A. Cooper, Desault, and others, but the operation performed by our author appears to be decidedly the best.

In the remaining chapters are considered, the management of the finger-nails, and their diseases, warts, chilblains, and the general management of the feet, but for these we must refer to the work itself, which is a valuable production, and deserves commendation for its utility.

Extracts from the First Report of the Institution on the Abendberg, near Interlachen, Switzerland, for the cure of cretins. By Dr. Guggenbuhl. Translated by W. Twining, M.D., late of Balliol College, Oxford.

This Institution, according to several accounts that have reached us, has been instrumental in effecting much good in a district where its services are particularly called for. Dr. Twining's object is to interest British benevolence in support of Dr. Guggenbühl's efforts, and the gracefully recorded cases in the pages before us, offer, we must own, strong encouragement for a generous response to his appeal.

TRANSACTIONS OF LEARNED SOCIETIES.

Royal Medical and Chirurgical Society, May 13, 1845. Dr. Watson, Vice-President, in the chair.

On the use of Creosote Injections in Camp Dysentery. By John Branston Wilmot, M.D., Cantab. &c. Communicated by Dr. Watson.

By the term "Camp Dysentery," the author means that epidemic form of the disease which has so often proved a deadly scourge in communities, and not those occasional cases which seldom prove fatal under proper treatment.

On the 3rd October, 1844, the author was requested by Mr. Dakins, surgeon of the Tonbridge Union House, at Bembury, to visit the house with him, as a fatal dysentery was raging there. The building is well situated, high and dry, and well drained. Dysentery was prevailing in the neighbourhood, but not in the same severe form as in the Union House. Four cases had proved fatal, and two were in a dying state. Those suffering from the disease in a less advanced stage, had constant discharge from the bowels of blood and shreds of mucous membrane, without fœcal matter. The stench of the dejections was that of putrid animal matter; vomiting was present in some cases; loss of appetite in all. Tongue not unusually dry until the last stage; pulse feeble; skin harsh and dry, but not hot. Abdomen not tense nor painful, but the tormina and tenesmus very distressing. There was from the first extreme prostration of strength, and as the disease advanced, low muttering delirium.

The remedies used had been chiefly calomel and opium, opiate injections, astringent mixture, with catechu, &c. It was agreed to give opium freely, especially in injection, nutritious diet, and brandy when required; bleeding was out of the question, and calomel was neither indicated by present symptoms nor past experience. The first care was to introduce a more generous diet among the inmates, the regulation of which was left to the discretion of the medical officers.

On the 10th (a week after) the author visited the house again, and assisted at the *post mortem* examination of two fatal cases. In the first, that of a man, aged forty-five, there were injection and ecchymosis on the inner part of the ilium; of the mucous membrane, only a tracery work like lace was left. On the cæcum were ulcerations, partially cicatrised. The ulcers did not extend to the colon; liver and gall bladder healthy. In the second case, a girl, aged six, there was considerable ulceration of the rectum and last three inches of the colon. Several cases had occurred since the third. The most pressing was that of a man, aged fifty-one, who was attacked on the 1st, and in whom the remedies up to this day (the 11th) had been of little or no avail. He was greatly exhausted, had constant evacuations of blood, with shreddy matter; no fœces, the smell was putrid and gangrenous. Hot turpentine fomentations were ordered to the belly, and in addition, the author was led to try an injection composed of ʒi. of creosote, in ℥xij of starch. He did not, he observes, use it empirically, but looking at the character of the fever, of the low nervous kind, the inertness of the remedies introduced by the stomach—the little control exercised by the medicines locally applied to allay spasm of the gut—the local nature of the disease, as shown by inspection of the bodies—the disposition to gangrene, as well as ulceration, and the antiseptic and stimulant powers of creosote—these considerations induced him to try the remedy. On the 12th the patient was rather better; the injection had caused a tingling sensation, but no pain. On the following days he gradually improved, and on the 18th the evacuations were copious, highly offensive, containing a quantity of hard scybala; no blood nor shreds were passed. The turpentine had been applied four times, and the creosote injection used every night since the 11th. After this he soon became convalescent. In several other cases, either under the observation of the author, or his friends, this remedy was used, and with evident advantage. The number of cases that occurred in the Union House was thirty-four, the deaths eight.

It may be objected, the author remarks, that my field of observation was too limited to arrive at any satisfactory conclusion; but so marked and undeniable was the success of the measures adopted in the few cases brought under my notice, and so confident do I feel that they would have been equally efficacious had the disease continued to spread, that I will venture to expose myself to such an objection, rather than withhold the publication of results, which may at a future time assist in arresting so fearful a disorder.

Dr. Webster was anxious to learn from Dr. Wilmot whether he had exhibited the creosote in these cases of dysentery prior to the change that had been made in the diet, as it appeared to him that the improvement was principally owing to that change. The diet at the union-house was very poor indeed, and his attention had been particularly attracted by the large quantity of cheese which was allowed.

Dr. Wilmot said, that the diet of the sick was unlimited; the improvement in the dietary was consequently directed solely for the benefit of the healthy, and the cases that occurred after it had been generally adopted in the union-house, were much less severe, and dwindled down to mere diarrhœa. The creosote was used in severe cases only, when the sufferers could not take food, and consequently for them the improvement in the dietary was absolutely nugatory.

Dr. Dickson enquired of Dr. Wilmot, as the dose of creosote which had been exhibited was very large, whether any indications of its action on the nervous system, such as intoxication, had been observed, and also whether the urine had presented any peculiar appearance, as in Dr. Macleod's cases, in which that secretion somewhat resembled Indian ink.

Dr. Wilmot observed, in reply, that he was not able to answer the question, as he was not residing on the spot, but Mr. Dakins had told him that it had produced great excitement, and that it seemed to cause quite a revolution in the system.

Dr. Baly had heard with great surprise a statement in the paper, to the effect that calomel had been perfectly useless in the treatment of the disease, and he referred to the existing evidence of its efficacy, and more particularly to Dr. Latham's work, descriptive of the epidemic of dysentery in the Penitentiary in 1823, when the use of calomel and opium soon cut short the disease. He felt surprise, if the disease were at all severe, that calomel and opium should not prove of service, and that such a remedy as creosote should arrest its progress. He could conceive, that it might be of use as an adjunct, but not as the principal remedy. He (Dr. Baly) had found sedative injections sometimes of service; that which he employed consisted of two drachms of tincture of opium, combined with starch, and he had also found a combination of starch and black-wash sometimes succeed, when other applications had failed. He was, therefore, ready to admit, that creosote may sometimes be of use, but still he

could not understand how so local a remedy could be successful in the treatment of inflammatory dysentery. He agreed, however, with Dr. Wilmot that the disease, when appearing as an epidemic, might present a difference of character. The number of cases which had been treated by Dr. Wilmot was very small, and not sufficient to found an opinion on, with respect to the efficacy of creosote.

Mr. Lloyd enquired of Dr. Baly what quantity of black-wash was used in the injection?

Dr. Baly, in answer, stated, that three ounces of the lotio nigra, added to warm water, were employed, and were repeated three or four times in some of the cases. It was not a new remedy, but was mentioned in the works of more than one writer, and was much used in India.

Mr. Lloyd then enquired whether ptyalism had been produced by its use?

Dr. Baly replied, that ptyalism had certainly been produced, but not from the use of the black-wash. It was caused by the calomel, which he had given in ten or fifteen grain doses, so that from twenty to thirty grains were exhibited in the course of the day. When ptyalism was produced, the patients generally recovered. Although many cases had occurred, the deaths in the course of the year from dysentery, when the complaint was unconnected with any other malady, were only nine.

Dr. Burrows concurred in the opinion expressed by Dr. Baly.

Dr. Wilmot observed, that calomel had been used in several cases before he was called in, and in every instance without effect. The patients were all either dead or dying. Laudanum and starch were also freely employed, but were without any efficacy. The creosote was not used as a sedative, but as a stimulant to rouse the failing powers, in which it proved successful. He then apologised for the paucity of cases, and said that it was not his fault that there were not more.—(laughter.)

Dr. Cursham enquired of Dr. Baly if there had been any change of diet in his patients, previously to the employment of the plan of treatment he had described?

Dr. Baly replied, that no change had been made in the diet, which was much more abundant than is the case in most union-houses. The prisoners had twenty-five ounces of meat a-week, besides other articles.

Dr. Watson enquired whether out of the large number of cases seen by Dr. Baly in the Penitentiary, there were any evidences of contagion? Whether, in fact, the disease appeared to spread from one person to another?

Dr. Baly had not observed any circumstances which would lead him to believe in its contagious character. When the disease was in the wards, patients admitted labouring under other maladies, were certainly seized with it, and so far it may be said to have been contagious, but he believed that it depended on atmospheric causes. When epidemic, it broke out in different parts of the prison at once, between which there was not any immediate communication.

Dr. Julian Evans enquired if there were any intermittent or remittent fever prevalent in the prison at the time?

Dr. Baly replied, that there was no fever at the time, and very little febrile excitement attended the attack.

Dr. James Johnson had seen a great deal of the disease, and had never had any reason to look upon it as a contagious malady. He considered the exhibition of calomel and opium, and perfect quietude in the horizontal position, as the most likely means of saving the patient; in fact, this plan was quite the sheet-anchor in tropical climates. When ptyalism had been induced, very few die, unless such a degree of ulceration had occurred as to place the patient beyond all aid. He had lately derived much benefit from the use of tannin; it was not so irritating as creosote, and could be readily injected into the bowels. It was a most powerful astringent.

Dr. King referred to the epidemic of dysentery, which occurred in the Deptford union about two years ago, and which was referred to bad drainage. The mortality was very great, principally among the females, who also suffered from a great discharge of blood from the vagina. The medical attendants told him that they derived most benefit from the application of leeches, and the exhibition of croton oil.

Dr. Baly was glad to find that Dr. Johnson's experience with respect to calomel coincided with his own. He wished to ask him, in what doses tannin was administered?

Dr. James Johnson replied, that he gave it in very small doses, from one to three grains internally. With regard to the quantity of calomel, he had himself taken it in twenty grain doses for several days, and had given it in hundreds of cases besides.

Dr. Wilmot enquired whether, in such cases, the liver was not affected?

Dr. James Johnson answered, that the liver was generally affected in hot climates; it was the primum mobile of the complaint.

Constitutional Syphilis in the Father a Cause of Repeated Abortions and Subsequent Infection of the Fœtus born at the Full Period, the Mother remaining wholly Free from Disease, with Observations, by William Acton, Esq., Surgeon to the Islington Dispensary.

The author remarks that the Medico-Chirurgical Transactions, as well as Treatises on Venereal Disease, furnish numerous instances of syphilis in infants, dependent on previous contamination of the mother alone, or of both parents; but surgeons and accoucheurs have hesitated in believing that the male can infect the embryo without infecting the female. Three cases are brought forward in order to elucidate the point in question.

M. H, nine weeks old, was brought to the author by its mother on account of an eruption, chiefly papular, over the whole body. The voice was hoarse, and there was a slight discharge from the nose; the palms of the hand presented a scaly, copper coloured eruption. Emaciation was less than is usually observed in children labouring under syphilis, but the peculiar earthy hue of the skin generally is very evident. The mother states, she married four years ago, became soon after pregnant, and at the full time produced a dead child, the skin of which was dark coloured and peeled off on the slightest touch. During the following year she miscarried. On the occurrence of the third pregnancy, the child, the present patient, was born at the full period, perfectly healthy. During the third week, spots were observed on the genital organs, and they have been increasing up to the present time. No symptoms, either of the primary or secondary disease, could be discovered in the mother. The father, about four years ago, contracted chancres, was salivated, and secondary symptoms followed. He again took mercury, and believing himself cured, married, and denies having had any primary symptoms since, but has occasionally seen white spots on his mouth and tongue; has not remarked any spots on his body. There is nothing at present in his appearance to bespeak syphilis, nor can any recent marks of infection be discovered. The author directed an ointment, composed of unguent hydrarg. nitrat. and spermaceti, to be applied to the affected skin, and a powder, containing two grains of hyd. c. creta, to be given at night. Within a month the child was free from disease, and had regained its healthy appearance. The author gives an abridged account of two other cases of secondary syphilis in men whose wives were free from all disease, but had miscarried. He remarks that these cases furnish three instances of males affected with constitutional syphilis, who marry, and yet fail to communicate any disease to their wives, thus far corroborating our experiments, that secondary symptoms are not inoculable, or capable of transmission from an infected adult to a healthy female. They, moreover, make it probable that a man thus infected may so far exercise a morbid influence on the embryo, the result of cohabitation between him and a healthy female, as to cause its premature expulsion or disease, insomuch that soon after birth secondary symptoms will appear. The first case further induces the belief that though syphilis may produce miscarriage, a healthy child can be subsequently born, although no mercury be given to either parent. If it be true that the father can infect the fœtus, without contaminating the mother, it justifies the surgeon in sparing her a course of mercury, and may induce him to treat the child with some mild mercurial, without fear of it being reinfected by the milk of the mother, thus offering additional evidence that the mother does not participate in the disease which the child inherits from the father.

Dr. King remarked, that Hamilton, of Edinburgh, was of opinion, that, in all these cases, both parents should be placed under the influence of mercury. He then mentioned two cases, illustrative of secondary symptoms of syphilis in the infant, the mother remaining untainted, and added, that Sir Benjamin Brodie recommends the children thus affected, a mercurial belt, composed of a roll of flannel, anointed with the ung. hydrarg. dilut., covered externally, with oiled silk. He (Dr. King,) thought this a very desirable plan of treatment.

Dr. James Johnson observed, that the male child inherited the peculiarities and diseases of the father, and he did not think that the mother could be affected by constitutional syphilis in her husband.

Mr. Simon quoted several cases from Schmidt's Jahrbucher, and Casenave's works, in support of an opinion emitted by him, that in every case where the infant laboured under syphilis, it was the result of infection in the father, received after marriage, and further, that the primary disease must have manifested itself in the mother, but in a milder form, so as to have been passed over without notice.

Mr. Arnott had no doubt that the infant might be infected with syphilis from a taint in the father, the mother being perfectly free from the disease, and he related a case, which had occurred in his practice at the Middlesex Hospital, in support of his opinion. He had had but little experience in the treatment, but a very competent authority, Mr. Colles, of Dublin, had said, that if mercury were properly exhibited to the parents, healthy children would afterwards be born.

Dr. W. Merriman mentioned some cases in point, from his grandfather's practice.

Mr. Wade had commenced practice in the belief, that children could not be born syphilitic without the mother being infected, but he had been led to change his opinion, from having met with several instances, in which children had been so affected, the mother being free from disease, and the father labouring under scaly eruption, nodes, &c. There was no fact in medicine of which he was more thoroughly convinced than this.

Sir George Lefevre then rose to address the society, but the confusion was so great from gentlemen leaving, that we were unable to catch a single word he uttered.

Mr. Acton regretted that his paper had been read at this late hour of the evening; it prevented him answering any objections made to his views. He begged, however, to assure the society that he would not have introduced the subject, did he not believe that the cases detailed differed from nearly all on record, in possessing an accurate description of the disease in the child, the symptoms in the father, as well as the negative evidence in the mother, furnished by examination. His object in the present paper, was to show the real influence of syphilis in inducing abortion, not, as some supposed, an indefinite time after its cure, but to point out the possibility that a man can contaminate the fœtus, during the period he himself is labouring under secondary symptoms. If any member was desirous of loose statements of wonderful cases, founded on insufficient evidence, he, (Mr. Acton,) could furnish him with abundance from books. His object, however, was to take the opinion of practical surgeons of the present day, on this interesting point in the paper. Another no less practical indication, he believed he had pointed out in this communication; he alluded to the treatment based upon it. It had been laid down as a dogma, that if healthy children were desired, both parents must undergo a course of mercury. Now if his (the author's) views were correct, the mother may be spared the inconvenience of a

course of the mineral, which in private practice was often of great importance, when the previous indiscretion of the father had better be concealed from the family. Moreover, giving mercury to the mother or nurse was the most objectionable plan conceivable. Mercury, by disordering the nurse, changes the character of the milk, and the child suffers most severely. The great mortality among syphilitic children, Mr. Acton attributed to giving mercury to the mother whilst nursing; he preferred always administering it to the infant, however young, when, as in the instance in question, it produced the very best effects, particularly when the mild preparations were used.

NOTICES TO CORRESPONDENTS.

Samuel Hadwin, Esq. Surgeon to the Lincoln County Hospital, *addresses through us to the National Association of General Practitioners a forcible and extremely well-written letter, which, except by a delay that would give its apposites, we cannot do more than shortly abstract. Mr. H. commences with a hope, that the same efforts of the profession and the press which have converted Sir James Graham from very erroneous to much-improved views of Medical Reform, may lead to further enlightenment. He then shews, that the public have the deepest interest in sound Medical Reform, though from finding they had for their time a sufficient supply of good Practitioners, they do not much interest themselves in it; that General Practitioners should be competent for "ordinary" and extraordinary "exigencies" since they are called to both, and the more so to the latter, since the poor they principally attend are the more liable to the graver accidents which need immediate treatment; that physicians and "pure" surgeons are in fact called in principally not to extraordinary emergencies, but to chronic cases, and that therefore General Practitioners should have at least as prolonged an education; that the character of their extended and varied practice is favourable to their acquiring comprehensive and just opinions on disease, and that therefore on the Board of Health, they should sit in greater numbers than two; that the emanating practice of druggists who begin to visit, should in common sense be repressed, and that the preliminary Board should be destroyed, or an equal number of General Practitioners placed on it. He finally warns the Association against the blandishments of Sir James Graham, and against accepting the Bill if not further improved, and enforces the duty of at all times and places resisting the late innovation in the College of Surgeons.*

Samuel Wood, Esq. House-surgeon to the Salop Infirmary, *proposes, that a county meeting of medical men should be held in every county town, (absent members sending a written statement of their opinions) that one or two delegates should be appointed; that the aggregate London conference so formed, should wait on Sir James Graham, should lay before him their views, in writing, and if necessary, call on their different Members of Parliament, to support their views. He suggests a subscription of ten shillings or a pound for each member to pay expenses.*

Iota *writes, that the Association should urge the expunging of that portion of clause 13, which requires the source of a diploma to be registered. He thinks its retention would injure the harmony of the profession; he insists likewise that six general practitioners should be on the preliminary Board.*

Several quack notices have been sent to us. The hand-bill by Mr. Henley, surgeon, Croydon, is not decorous nor gentlemanly. That by Mr. Rigget is insufferably quackish. Cannot the public be so well taught by the legitimate *profession of the unprincipled character of those who take low and illicit means of getting practice, that empiricism may become profitless. A proper combination might do much. We should like to see an ante-empirical society formed and well supported, whose object would be by tracts and appeals through the Journals to unmask quackery, and enlighten its dupes. It would deal destruction on many patent medicines now in same repute.*

Mr. H.—*We are tired of repeating that our Pharmaceutical Number is wholly distinct from the subscription of one guinea; gentlemen who receive it under that impression and do not wish its continuance have only to [illegible] us on the same cover, and we shall remove their names from the "Pharmaceutical Roll." The subscription for the Pharmaceutical Numbers is 6s. per annum stamped. A volume will extend through two years.*

Mr. Bree *announces to us that the annual meeting of the Suffolk branch of the Provincial Medical and Surgical Association, will be held at Ipswich on Friday the 30th instant.*

A Subscriber.—*We are not acquainted with any such party. Our advertising page contains some information on the point.*

Mr. Lambe.—*The mistake has been rectified.*

Sir W. Hamilton, Bart.—*We have received from this distinguished* savant *a very important communication containing more researches on the Frontal Sinuses which we shall publish in a very early number.*

Mr. Brooks *sends us a copy of a letter published by him in the* Shrewsbury Chronicle. *It appears to us inaccurative in its views, and not to be applauded in its policy.*

Alpha *has our best thanks.*

Mr. Hillier *brings under our notice a new Institution, called the London Dental Hospital, which makes a strong appeal to public support. Since 1840 it has relieved more than 8000 sufferers. The medical officers are* Dr. Sayer *and Messrs. Mac Murdo, Harrison, and Saunders.*

G. D. B.—*Our foreign numbers are expedited with the greatest regularity. The fault must be with the post. The circulars have been properly disposed of.*

T. W., Liverpool.—*We never prescribe through the* Medical Times. T. W. *should consult a discreet practitioner, to whom the case will not appear at all marvellous.*

Mr. Black *has exercised a sound discretion. He does not receive his numbers from our office.*

"A Member of the National Association" *proposes an appeal by the Society, to know what title would be preferred for the new College, and suggests "The College of Medicine and Surgery," with or without the addition of Midwifery.*

A Two Years' Subscriber.—*The case is rather an exceptional one—but we imagine he may become a Fellow of the Royal College of General Practitioners. The supplemental register will allow our subscriber to register by his precise qualifications.*

The House Surgeon's *case of Coroner's law is hopeless, we fear. The Coroner had the power to order proper remuneration, but he cannot, in this instance, be compelled to exercise it.*

We have to thank Mr. Spencer Hall for his courtesy: but the claims on our space just now are too numerous and pressing to allow of our profiting by it.

M. R. C. S. and L. A. C. *has overlooked the Supplemental Register—in which all existing Practitioners can register themselves under* all *their present* legal *titles. They can, consequently, recover as General Practitioners though registered as Surgeons, and will be allowed to call themselves both Surgeons and General Practitioners.*

A Subscriber *writes in energetic terms against the source of diplomas being registered. He thinks such a scheme pregnant with dissension and jealousy.*

Verisopht.—*We must decline lending our aid to* Verisopht *in the loose habits it seems his pleasure to indulge in. The only sure "escape" is to become a good member of society.*

The Poetic Effusion from Ashton-under-Lyne is too pungent for our columns. We decline the responsibility of so worthy a citizen's suicide.

Graduatus.—*A Physician so registered under the new Bill, cannot under any circumstances, save special contract, recover for attendance. We do not know that the new Bill will introduce any change as to the mode of addressing* General Practitioners.

Amicus Paupertatis *might go to Paris, or Montpelier, or Strasburgh, or Edinburgh.*

E. M. P. *was right in his opinion: no change has been introduced. Letters meant for the Editor when addressed to Mr. Carfrae cause much extra trouble. Business letters alone should be sent to Mr. Carfrae.*

Mr. M'Intosh's *letter is full of interesting matter—we are certain—but we cannot read it.*

X. Y. Z.—*Any physician in legal practice can become a Fellow of the* New College *of* General Practitioners *and may register we apprehend from the present wording of the Bill, as he may please either as* General Practitioner *or* Physician.

Twelve months after the passing of the Bill, a physician would have we presume to undergo an examination if he insisted to be a Fellow of the New College.

A very old Subscriber, *will register as a General Practitioner, and retain all his former privileges.*

Discipulus.—*We think the preliminary examinations will be like the matriculation examination of the University of London. Every student should seek to undergo it, but our correspondent, if no change be made in the Bill will not be subjected to it.*

A Reader.—*Lupuline may be obtained at Mr. Bullock's in Conduit Street.*

H. B. *writes*:—"A worthy chemist who has some "speculation in his eye" has just issued to the world three new patent medicines, heralding them forth as made from prescriptions of the late Sir Henry Halford; they have already become "celebrated" at last so they are declared, and the proprietor has a certificate from himself, or some friend signing—A Member of the Pharmaceutical Society, speaking in extacies of their success. Are the public to be cheated by impostures so transparent? Will they never understand that a medicine, good in one case of gout for example, may be murderous in another?"

A notice of the modifications made in committee on the Bill for granting new charters to the College of Physicians of London, *the* College of Surgeons of Edinburgh, *and the* King's and Queen's College of Physicians in Ireland, *will be given in our next.*

X. Y.—*The dinner to Mr. Wakley is abandoned.*

THE MEDICAL TIMES.

SATURDAY, MAY 24TH, 1845.

Antefero
Iniquis tutam pacem justissimo bello.
CICERO.

ARRIVED at a moment of indescribable importance to the future fortunes of medicine, we are not only in a crisis national in its magnitude, but at its climax. Generations of medical men have passed by, and will again, without witnessing an epoch so pregnant with influence; and to enhance to us its gravity, on *our* deportment during these few days will depend the whole result. The Government Bill, and with it the Profession's fortunes for an age, awaits its doom at *our* judgment-seat. *Our* decision will determine—*and we speak on undoubted authority*—whether the Amended Bill shall become law forthwith, or be relinquished by the minister in disgust for ever. The privilege if high and important, is not less responsible, and at the shrine of the mighty interests involved, we earnestly entreat that, before passing judgment, we may depose every thought and every feeling misleading to the mind, or discreditable to the heart.

Calmly, dispassionately, and impartially examining the Bill, *that we have now to choose or reject*, the first conviction that forces itself on the mind is that, on the whole, it is a vast improvement. It does not settle *all* our grievances, and therein we blame it; but it *does* settle many. In its last improved stage, it is a mighty reformer of those family heritages—our snug and insolent corporations. It puts them under thorough control. In the Council of Health, it gives them a master, that must do both them and us right. They get a ruler—we a court of appeal. The Council will play the overseer to *them*—Parliament and our medical press will do the same for *it*. This is responsibility—a double, tangible, practically available responsibility.

True—as we have mentioned—the Council might be made more responsible by selecting more of its members on the principle of election. But it is much to have this great, all-potent, national board of supervision even partly constituted by election. It is something to *gain* the power of nominating on it two of our own men, who, the

worthy recipients of a high honour we never could confer on desert before, will enlighten Government on our wants, watch over our interests, apprise us of danger, and guide us, if need be, to defence. This is a feature in the Council of direct and immediate responsibility to, at least, the General Practitioners.

Besides, the Council is so diversely constituted that on any given question the majority will be without a personal interest to warp their judgment. The Colleges of the three *kingdoms*—six in number—have no common bond of unity. They never can form a business partnership, for they have antagonist interests. There is no more bustling agitator for reform than a displaced or maltreated corporator. The surgical college of Edinburgh does not thrive by the superior attraction of that of Dublin and neither feel very desirous to prop up the declining fortunes of that of London. The Colleges of Physicians, not much better agreed mutually, are in no greater amity with the Surgeons. The Professors of the Universities again—London having its representative, we are glad to say—have another set of aims to look to, and the four Government nominees seem promised altogether no small field for their services as arbitrators. Amid all these opposing views and policies, the two delegates selected by the General Practitioners for their superior ability, will need no extraordinary powers of diplomacy to defend the interests of their order. Whatever objections, therefore, we may allege against the Council's construction theoretically, we see no improbability of its acting very well practically; but in any case, we have always the check offered by the presence of two gentlemen really chosen by the Profession, and by the appeal ever open to the press and Parliament. This latter consideration is so strong on some minds, that we have met not a few who, seeking a Council of Health as a necessary instrument of great practical reform, would prefer that all its members, like the judges, should be appointed by the Crown.

We pass by the question, to what extent, or in what way the Council of Health, even if ill disposed, can injure the standing or progress of the General Practitioners. The responsibility of any such attempt would not be small, and the chance of success anything but considerable. But while we are far from seeing the mischief that can arise to the numerous class of the Profession we refer to, we see infinite good that must arise. The disgraceful competition of the Colleges and Universities which shall make Medical Men on the easiest terms will be annihilated. The highest standing of Education that now *any* where prevails will be made to prevail every where. For the future, the Council will guarantee us, that no new man shall enter our body, under five years study, instead of the two and three years, which in many Institutions sufficed. The age of twenty-two will replace that of twenty-one, which, in most of the Scotch, and some of the Irish Colleges, was sufficient to constitute a Surgeon or M.D. The fees again, which, often at great inconvenience, sent an Englishman to Edinburgh, or a Scotchman to Paris or Dublin, in the cause of economy, will be so equalized, that the only incentive to prefer the examination and diploma of one College to another, will be its superior repute—a fact, that must lead to mutual emulation, and scientific progress.

So far then, we are entitled to claim for the Council the credit of prospective utility, for, as we have seen, it forms the supervising general body we have all along asked for as necessary, and is a considerable improvement on the constitution of the Council first proposed by the Minister.

Our own opinion is, that the Council of Health is by far the most important feature of the Bill, and that on the question, whether it can be made useful in raising the dignity and efficiency of the Profession, depends greatly the policy of giving a general support to the Bill. If our readers share our opinions on the subject, they will hesitate much, before they sanction any course of opposition which, postponing the Bill for this Session, will inevitably postpone it for ever.

Another vital innovation in the Bill is the concession to nine-tenths of the Profession, of a Government managed by themselves. We have depreciated the pure Surgeons—we have disclaimed connection with the Physicians—we have repudiated the Apothecaries. The last disgrace us by their bad name, and low offices; and the former would attempt to degrade us, to raise themselves. We have further claimed for ourselves, responsible government—to have submitted to scrutiny our accounts—spend our own money—appoint our own officers, and have asserted highly, that if we could promote our men to our own offices, a competition of worth would be established, which would vastly aid science. The new Bill gives us all we asked, while leaving us every privilege we before possessed—a new Institution—a Royal College of the Kingdom—managed precisely on the principles we have recommended, and thrown entirely under our own guidance. Whatever we can do for science, and ourselves, in a fair competition, is now conceded us. If we, the General Practitioners, can establish a National College of Medicine in honour, and sustain it with glory—and who will deny it—the opportunity is in our hands.

These constitute the two great features of the Bill, but there are others that deserve serious consideration.

1. Quackery, though not suppressed, is far more stringently dealt with than before the New Bill. The wolf can no longer prowl in sheep's clothing; and the old laws for abating the nuisance in all its forms, are left exactly as they were.

2. Education is equalized, and considerably raised.

3. A preliminary examination is established, to show whether Candidates can commence or not the study of medicine, with those aids which alone reasonably promise success.

The Board *at present* constituted for this examination is ill-composed, but the examination will be most useful.

4. The power of the Council of Health to fix certain classes of medical men for certain medical offices is abandoned, as is also every tendency of the bill as originally drawn to reduce the standing, education and competency of the body of General Practitioners.

5. General Practitioners are authorized to demand legally full remuneration for their services in a Court of Law, and will meet no further technical difficulties in the establishment of their claim.

6. The whole Profession will be registered, and both we and the public will know authoritatively who are of us and who are not.

Now, taking all these actual improvements into account, our readers will see how immense are those changes on the former drafts of the Bill—nothing actually lost to us, and much gained—it does strike us that at a moment when the Minister comes forward with the declaration, "I have done all I can: if you will not accept this, I will give it up in despair"—and this, we know, is his actual declaration;—it does strike us, we say, that in mere common prudence and self-interest we are bound to close the contentious bargain, and come at once to an understanding.

There are, doubtless, some points of detail which further thought will show to both sides should be changed; but on the general question of rejection or acceptance—aye or no?—we cannot but think that the Profession will exercise a wise discretion in saying with the National Association—"We accept." In taking the boon offered we compromise no right, and as our differences with the Surgical Council are hearty and fresh enough to keep, we lose nothing by postponing their consideration for a more fitting hour. In the meanwhile let the new Corporation flourish as it should, and it may be, that even without Parliamentary aid we may have the Surgical Council at our feet much more early than we yet, perhaps, anticipate. *It counts for something in the siege to cut off the supplies.*

THE PROVISIONS OF THE NEW BILL.

The amendments in the Bill are so fully given in the abstract we published last week that we may content ourselves with publishing *verbatim* only the clauses which call for special attention to their wording. From clause 1 to 14 we have a mere reprint of what we published in No. 285, except, as we have before shewn, that the clause repealing former statutes is considerably more perfect; that two Members of the Council of Health are given to the New College of General Practitioners; and that the registration of the FUTURE profession will be in the three divisions of Physicians, Surgeons, and General Practitioners. The following is clause 14; the important points placed in italics:

QUALIFICATIONS OF GENERAL PRACTITIONERS.

"And be it Enacted, That every person shall be entitled to be registered by the Council as a General Practitioner, who, *at the time of the passing of this Act*, shall be legally practising, or entitled to practise, as a *Physician*, *Surgeon*, or *Apothecary*, in some part of her Majesty's dominions, *and* who, within Twelve calendar Months after the passing of this Act, shall be qualified to be enrolled, and shall enrol himself as a *Fellow of the Royal College of General Practitioners* in Medicine, Surgery, and Midwifery of England, *or* who shall have attained the age of Twenty-two Years, and shall have been examined by the Colleges hereinafter named; (that is to say) if in England, examined by the Royal College of General Practitioners in Medicine, Surgery, and Midwifery of England; or if in Scotland, examined by the Royal Colleges of Physicians and Surgeons of Scotland; or if in Ireland, examined by the Royal Colleges of Physicians and Surgeons in Ireland, after such proof as shall be satisfactory to the Examining College or Colleges, that *he has applied himself to medical and surgical studies during at least five years*; and in every case shall have received Letters Testimonial from each of the bodies by which he shall have been examined, of his being duly qualified to practise as such General Practitioner,

Our readers will observe, that Physicians and Surgeons (Fellows or not) may become Fellows of the New College and register as General Practitioners. That many will do so is extremely probable; for the Bill (clauses 32 and 34) empowers General Practitioners *alone* to recover for medical and surgical attendance, as well as for the supply of medicines. Physicians also, and Surgeons who supply their own medicines, can be prosecuted (clause 36) if not Fellows of the College of General Practitioners.

The Surgeons, by clause 31, must shew one of two kinds of qualifications. 1. Age twenty-six (instead of twenty-five); examination by one of

three surgical colleges; and five years study (the same as the General Practitioners); or else he must have undergone a General Practitionership of twelve years standing, or a Membership or Licentiateship of one of the surgical colleges of the same duration, and a further surgical examination. Thus the *age* of the Surgeon will be greater than that of a General Practitioner—the study the same. The result will be, that all these *future* Surgeons or Physicians, desirous of getting into practice before reaching twenty-six, will become Fellows of the Royal College of General Practitioners. Once there, it will depend on the repute the Colleges of Surgeons or Physicians can make for themselves, whether they will ever feel it worth while to go further.

The Physicians are thus to be formed:—

"And be it enacted, That every person shall be entitled to be registered by the Council as a Physician who shall have attained the age of Twenty-six Years, *and* shall have graduated as a *Bachelor or Doctor of Medicine* in some University of the United Kingdom of Great Britain and Ireland, *or* (subject to the restriction hereinafter contained) in some *foreign* University, *or* shall have graduated as a Master of Arts in the University of Oxford or Cambridge, *and* shall afterwards have received *a license to practise* Medicine, *after due examination*, from the same University, and shall *also*, in *each* of the foregoing cases, have been *examined* by one of the Royal Colleges of Physicians of England, Scotland, or Ireland, after such proof as shall be satisfactory to the Examining College that he has applied himself to medical studies during at least *Five Years* (or who shall have attained the age of *Forty Years*) *and* shall have been registered as a *General Practitioner or Surgeon* under this Act, or was at the time of the passing of this Act legally practising or entitled to practise as a Physician, Surgeon or Apothecary in some part of the said United Kingdom, and shall have practised Medicine for *at least Twelve Years*, and shall have been examined by the Royal College of Physicians of England; and in each case shall have received Letters Testimonial from the Examining College of his being duly qualified to practise as a Physician; *and no person shall be entitled* to be received for examination for the purpose of being so registered as a Physician *upon a foreign Degree* in Medicine, *unless* the Royal College of Physicians of England, Scotland or Ireland shall give him a *special certificate*, to be laid before and *approved* by the Council of Health, that they have enquired into the manner in which such degree was conferred, and have ascertained that it has been granted after *due examination* and upon satisfactory certificates of previous study, *including residence and study at the seat* of one or more Universities, *during at least Three Years*, one of them at least being at the University by which the degree is granted."

The General Practitioner can thus enter the body of Physicians at forty—or, after twelve years medical practice, if he stand the test of the examination by the College of Physicians.

Clause 23 enforces on all Universities two years' matriculation before they can grant any *degree*, and as that degree will not entitle to registration, or consequently to practice, if a further step is sought by the candidate, he must prove before some College that he has at least given five years to study. Hence, in the next clause, by which the Universities are privileged to grant the right of practice to a select class called Licentiates of Medicine (Inceptors of Medicine in the former Bill), provision is made that five years' previous study should be first shewn.

The only other clause necessary to be reprinted is that on the Supplemental Register:—

"Provided always, and be it Enacted, that during Twelve calendar Months after the passing of this Act, every person legally practising or entitled to practise on the day before the passing of this Act as a Physician, Surgeon, or Apothecary in any part of the United Kingdom of Great Britain and Ireland, and during the period of Two Years after the passing of this Act, every person legally practising or entitled to practise on the day before the passing of this Act as a Physician, Surgeon, or Apothecary in any of Her Majesty's Colonies and Foreign Possessions, although not registered, shall continue to enjoy the same privileges and exemptions, and be qualified to be appointed to the same offices, and to practise in the same manner as if this Act had not been passed, and no further or otherwise, unless registered under this Act; and the said Council, on the application at any time of any person legally practising or entitled to practise, on the day before the passing of this Act, as a Physician, Surgeon or Apothecary in any part of the said United Kingdom, shall cause the name of such person to be registered in a supplemental register, as a Physician, Surgeon or Apothecary, as the case may be, specifying the nature of his qualification, and whence derived, on production to the said Council of his diploma, license or certificate, or such other proof as shall be satisfactory to the said Council, that on the day before the passing of this Act he was so practising or legally entitled to practise, and on payment of a fee of Five Shillings, which fees shall be applied toward the expenses of this Act; and every such person, upon being so registered shall continue to enjoy the same privileges and exemptions, and be qualified to be appointed to the same offices, and to practise in the same manner as if this Act had not been passed, and no further or otherwise."

This is sufficiently clear to require no further notice.

There are no other parts which have not been noticed, or are not familiar to our readers. They already know that Sir James Graham proposes to restrict public offices to registered practitioners; that with that exception the public may choose for public offices when they please; that false intruders are to be severely punished; that General Practitioners alone will recover for medical attendance; that neither the registered nor the unregistered shall assume medical titles that do not belong to them, under the penalties of a misdemeanour; that felons, or those who have got into the Colleges, or on the Register by fraud, shall be struck off; that to prevent traffic in degrees and licenses, examinations shall be uniform in the lowest as in the highest Colleges; that the fees of admission shall be the same, *cæteris paribus*, in all, and finally, that on paying, not examination, but *admission* fees, the practitioners of one part of the empire shall be admitted to the privilege of collegiate fraternity, and unrestricted practice in another.

When the Medical Bill shall have passed through Committee again, we shall endeavour to give our readers a *verbatim* reprint of its contents.

A vast number of the patients of Lisfranc at La Pitié are said to be suffering under erysipelas. In six cases of excision of the mammæ, erysipelas followed, and the slightest wound or contusion is said inevitably to produce it.

The following is the opinion of a consistent and very respectable contemporary on the New Incorporation, expressed Dec. 14.—"It would be pusillanimous not to acknowledge, that if the attempt which is now in progress for forming the General Practitioners of the kingdom into one voluntary Corporation for their own protection fail, such a disaster would at once decide the fortunes of the profession, and render certain the success of the Bill."

Gentlemen admitted Members of the Royal College of Surgeons on Friday, May 16th, 1845:—J. Strinfield, T. F. Grimsdale, J. W. Abell, J. Woods, T. C. Richardson, W. R. Hawks, T. C. Morison, H. F. A. Goodridge, J. Berry, C. Sproull, R. Allen.

THE MYSTERIOUS LADY.

To the Editor of the "Medical Times."

SIR,—The attention of the medical world, which is engaged in discussing the merits of the higher phenomena of animal magnetism, should be directed to the exhibition now attracting numerous and fashionable audiences in London—the *mysterious lady*, whose performances rival, if not surpass, the most renowned feats of clairvoyance. The mysterious lady requires no passes to get into her prophetic trance; but seating herself in a chair or on a couch *at one extremity* of a long hall, is prepared to describe with extraordinary accuracy whatever article may be deposited in a small open basket in the hand of her exhibitor, who goes round the assembled company to receive it, and to put the question to her, her back being turned towards the spectator's, and his back to her's. She then retires into a recess at the end of the hall, behind a curtain, and the exhibitor having requested any of the company to whisper into his ear the particular meat, fish, or fowl, for example, they would wish for dinner, calls out to her to name it, which she never fails to do. There is in this exhibition no apparent acoustic apparatus by means of which, as in the case of the invisible girl, the sound could be conveyed to her; and from the distance at which she is placed, with a thick curtain intervening, it can scarcely be possible she should hear a whisper. There can be no preconcerted system of words or letters, for the question also is always put in the same, or nearly the same words, and in the most direct manner,—such as "tell the gentleman what fish he has asked for;" and if I mistake not, he has in the same words, and at one bidding, desired her to tell more than one gentleman at a time the several fish they had each named to him in the lowest whisper, when she gave the names in succession—such as "trout," "salmon," "mackarel," they had respectively selected. It was immaterial, too, at which end of the room she sat, for when the company was too numerous to sit at one end, and some of them had to sit facing her at the other, she first satisfied the curiosity of those towards whom her back was turned, and then removed her chair to the other end and turned her back towards those she had previously faced. This is a sufficient proof that the sound was not conveyed to her through any concealed acoustic tube. When close to her, and watching her countenance as she answered the questions of the party at the further end of the hall, I observed that she answered more readily at some times than others, and occasionally betrayed a fretfulness of manner, as if she were a little puzzled to make out what the article was. When it came to my turn to name a fish, she being then with her back to me at the other end of the hall, where she could neither watch the motions of my lips, nor those of the exhibitor, nor possibly catch the sound, I called for a *grampus*, in the expectation that no sign had been preconcerted for so uncommon a dish. The exhibitor did not seem to relish my taste, but did not object to putting the question, when, after a little hesitation, as if she were uncertain whether there was such a word or not, she asked if it was *krampus* (grampus). I also tried to puzzle her by putting a farthing in the basket, and then placing my hat over it. Here, also, she appeared to hesitate, on which I remarked to the exhibitor, I think we have posed her at last; but I reckoned without my host, for in a few seconds she replied—"a cent." He had previously told me she was an American. In this instance it was curious, that, probably not knowing the word farthing, she named the coin equivalent to it with which she was familiar.

In several numbers of your journal of last year you published communications from correspondents regarding similar feats by other parties, such as the Highland Youth with the second sight, at Edinburgh and elsewhere, the report of whose performances at Bow-street in the presence of the Police Magistrate led the learned author of "Isis Revelata" to surmise that he might be under the influence of mesmerism, (vide page 339, vol. 2.) I would fain hope that the subject of this pre-vision, or fore-seeing, and *post-vision*, or *seeing*

behind one's back, as performed with such dexterity by the talented lady, will receive a suitable and satisfactory solution.*

I remain, Sir,
Your obedient servant,
AN ENQUIRER.

Edinburgh, 10th May, 1845.

[This lady, according to our correspondent, performs two feats—tells what may be placed in *her own* basket, and names a fish, named previously by some one else to *her* friend. Is our correspondent serious in comparing this *easy* jugglery with the facts *attributed* to mesmerism? All this, and a thousand things more, might be done if the lady were at Southampton and the audience with her friend at Vauxhall. Is there no such thing as an electric telegraph?—ED.]

* Perhaps, in the fulness of time, the *Quarterly Review* may favour us with a laboured article showing how the mysterious lady employs a scientific apparatus of acoustic tubes, as fine as a hair, and quite invisible to the eyes of the spectators, as were the magical mirrors which it placed at the command of the magician of Cairo, celebrated by Lord Prudhoe and Mr. Lane. Yet, mark how a plain story has put down the learned Theban of that magniloquent periodical. It turns out, as related by a recent traveller, that the interpreter was a Scotchman who had turned Turk, and played into the magician's hands. The interpreter was gathered to his fathers, and the oracle was struck dumb. See also an amusing account of the magician's blunders by the talented author of "Eothen"—page 203.

CHLOROSIS IN THE MALE.—Two cases of this disease, which it has hitherto been supposed was confined to the female, are reported in the *Dublin Hospital Gazette*, from the practice of Dr. Evans at the Jervis Street Hospital. The first case is that of a lad, 19 years of age, who on admission into the hospital, presented the following symptoms:—a loud *bruit de diable* in the cervical vessels especially of the left side, less perceptible on the right side; the sounds of heart distinct and natural, but accompanied through both sounds, and even during the interval of rest, by a hum like the whirr of a wheel rapidly revolving; over the middle and superior part of sternum a whip sound accompanied the first sound of the heart, the second being normal; the impulse and extent of dulness in the precordial region was natural. He complained of nothing else but some giddiness in the head, and occasional noises in his ears. His lips were not pale; he had no headache; his tongue was clean; appetite good; no epigastric tenderness; no thirst; bowels regular; he had no cough nor dyspnea. This lad acknowledged to have been in the constant practise of onanism for some years. The second case, occurring in a younger boy, from this cause, was more marked. The patient, 16 years of age, had been ill three years when admitted. His lips appeared red when contrasted with the extremely pale condition of his cheeks; his tongue red, narrow, with elevated papillæ, and channelled down the centre; there was some epigastric tenderness, but his appetite was tolerably good; he had no thirst, and his bowels were tolerably regular; he had slight cough, and had at different times spit blood after making unusual exertions; however, no physical signs could be detected in his lungs either upon auscultation or percussion; he had no headache, but occasionally lightness or dizziness, with sometimes noises in his ears; he complained that his sight was not so good as formerly. What chiefly distressed him was violent and constant palpitations of the heart, increased by exertion; the hand placed on the precordial region recognized a most remarkable fremissement. The boy's chest was somewhat deformed, with a lateral curvature in the spine, and the heart beat midway between the sternum and a line falling vertically from the nipple; but as far as could be collected from his account, he never had pleurisy or rheumatism. When examined with the stethoscope a bruit was heard accompanying both sounds of the heart, or, more correctly speaking, a bruit was heard with the first sound which continued along with the second sound, and during the interval, so that there was actually no period of silence, although there might be of repose. This bruit was of a curious rumbling character, that gave the sensation of a continued fremissement to the ear. The heart beat in perfect time; there was no irregularity in its action; percussion did not detect more than a natural amount of dulness; the impulse of the heart scarcely anticipated the pulse at the wrist; this pulse was not frequent, but jerking and thrilling; the peculiar sounds in the heart gradually diminished as the stethoscope was carried up the course of the aorta. There was a loud *bruit de diable* in the vessels of the neck. The urine was habitually high colored and scanty. There was no œdema in any part of the surface. Upon being questioned he acknowledged a habit of continual onanism. The saccharated carbonate of iron, with scruple doses of the bicarbonate of soda was employed, and after it had been used for twelve days, the boy manifested great improvement. The thrill in his pulse was much diminished, but was still perceptible; the musical murmur had almost ceased in the cervical vessels; the fremissement still remained in the region of the heart; the humming whirr in the same situation was gone, but a loud bellows sound was distinctly audible; loudest about an inch below and to the right side of left nipple, whence it gradually faded in ascending to the upper parts of the chest. This sound resembled closely the bruit of mitral regurgitation, but upon feeling the impulse of the heart, when listening to the rhythm, it became evident that the soufflet alternated with the impulse, and must therefore be in the second sound. The sound of the heart synchronous with the impulse was like a healthy first sound. The ear was sensible of a short interval of silence between the termination of the bruit and the commencement of the sound that was synchronous with the impulse. The motions of the heart were very quiet, and the force of the impulse not beyond the limits of health. In some interesting and important remarks addressed to his pupils on this case, Dr. Evans observed, that this was a case of extreme interest; first, on account of the existence in it of a bruit in the second sound below the nipple; and secondly, on account of this bruit having been to a certain extent complicated and disguised by chlorotic murmurs. When he first examined this case he had the assistance of his friend, Dr. Aldridge who remarked upon feeling the patient's pulse, "this boy has either chlorosis or permanent patency of the aortic valves." The next step was to examine the vessels of the neck, where they found no visible pulsation, but heard a loud *bruit de diable*. So far it seemed the case was one of chlorosis. They then placed the stethoscope about the middle of the sternum, and detected a double bruit; this again was calculated to puzzle, because they must all know that a double bruit behind the sternum is usually indicative of aortic regurgitation. However, upon pursuing the investigation they found that this double bruit increased in intensity as they approached the apex of the heart, where it became a continuous murmur. Now this is very different from what occurs in aortic valve disease; and, moreover, there was no proof of hypertrophy of the heart; and the pulse at the wrist and the impulse were nearly synchronous. They therefore decided that there could be no regurgitation; and the vascular signs could, therefore, be only accounted for on the supposition of chlorosis, the cause of which, on further enquiry, was found to be onanism. There was a great difference between the physical signs in this case and the previous one. In the latter there was merely audible a humming noise, accompanying the rhythm of the heart, although the musical bruit in the neck was just as loud as in this, in which, on the contrary, there was a distinct rumbling bruit accompanied by marked fremissement, alternating with the impulse, and, therefore following the first sound. This gradually subsided into a hum, and then immediately came the first sound also accompanied by a hum. These signs led to the belief, notwithstanding the absence of increased dulness, that there was some organic disease of the heart, which could be better examined when abstracted from the signs produced by the chlorosis. As there was some evidence of slight gastritis, Dr. Evans thought it better to begin by removing this complication; alcalies largely diluted were therefore exhibited for a couple of days, and the epigastrium was blistered. The boy was then put under the influence of chalybeates and ordered full diet. The chalybeates were combined with alcalies—a mode of administration which he borrowed from the practice of Dr. O'Ferrall, who discovered that in this way iron may be exhibited at an earlier stage after gastric irritation. His strength rapidly returned; the colour came back to his cheeks; the *bruit de diable* ceased in the vessels of the neck, and the chlorosis was removed by a multiplication of the blood corpuscles; the cardiac phenomena were now changed; the humming noise that previously accompanied the first sound was no longer audible; an integral was capable of being detected between the first and second sounds; but the strong fremissement continues up to the present, and the usual sharp defined character of the second sound is replaced by a bellows murmur. What is the nature of the cardiac disease which persists in this case? Dr. Hope supposed that a bruit chiefly audible below the nipple, and replacing the second sound, was indicative of contraction and obstruction of the auriculo-ventricular openings; but Dr. O'Ferrall has shewn that very great contraction of the mitral valves may exist without any bruit; and, indeed, the commonest valvular disease of the heart is the crescentic contraction of the mitral, described by Mr. Adams, in which there is both obstruction and regurgitation, yet whenever a bruit is present in this disease it always accompanies the first sound. Dr. Evans therefore does not believe that obstructive disease of the mitral valve ever produces a bruit. Dr. Graves has described a case of permanent patency of the aortic valves, where the signs exactly simulated those produced by regurgitation through the left auriculo-ventricular opening, but the aortic valves could scarcely be patent without producing hypertrophy of the left ventricle; while in this case there is no morbid dulness on percussion in the region of the heart. Again, there is a sign of regurgitation through either opening on the left side of the heart, first pointed out to Dr. Evans by Dr. Aldridge, namely, an alternation between the pulse at the wrist and the impulse of the heart; this sign is also absent, both pulse and impulse being synchronous. Dr. Evans does not, therefore, think that in this case the aortic valves can be inadequate. Dr. O'Ferrall has given the history of a case where bruit in the second sound proceeded from regurgitation through the pulmonary valves. In his case, however, the bruit was most audible at the base of the heart, over the seat of the pulmonary valves. Here it can be most distinctly heard at the apex. Under all circumstances Dr. Evans considered this case to be one of great importance, and although they might not at present be able to explain the cause, it would be well for the students around him to bear in mind that a bruit might replace the second sound at the apex of the heart, accompanied by fremissement, without any evidence of enlargement of the organ. Dr. Evans thought it as well to remark that there were in this case none of the ordinary phenomena of cyanosis.

EXTRACTION OF THE PLACENTA IN CASES OF PLACENTA PRÆVIA PRIOR TO THE BIRTH OF THE CHILD.—With reference to the controversy now existing on this subject, Mr. Blenkinsop quotes a statement from a work entitled observations in midwifery, by Percivall Willughby, Gentleman, who practised in Derby and Stafford, and afterwards in London from 1640 to 1670. Willughby says, if the flux of blood bee caused by the afterbirth, coming afore the birth of the child, or in the time of travaile,—before you attempt anything, these two points must be observed. First, whether the after-burden bee come forth but a little, or else very much. If it be but a little, (when the mother is well placed,) it must be thrust and put back again with as much care as possible bee; and, if the head of ye child come first, let it be placed right in the passage, thereby to help the naturall deliverey. But, if you find any difficulty, or, if you perceive that the

child's head cannot easily bee brought forward; then, without doubt, the best and surest way is, to search for the feet, (as we have said,) and to pluck him forth gently by them. The other point to be observed, is, that if the said after-birth bee much come forth, and that it cannot be put back again, (as well by reason of the bigness of it, as also of the flux of blood that commonly companies it,) and likewise, if the child follow it close, staying onely to come into the world, then must the after-burden bee pulled away quite; and, when it is come forth, it must bee laid aside, without cutting the string that cleaves unto it. For, by the guiding of the same string, you may easily find the child; who, whether he bee alive or dead, must be drawn forth by the legs with as much dexterity as may bee." —Dr. Willughby relates many strange cases and anecdotes, among others, "A strang, yet true accident, which happened at Ashburne, in Darbyshire." Emma, the wife of Thomas Toplace, having been five days in labour, "had a medicine given to her by a Doctor, of Divinity, (Dr. Kettleby,) pretending some small skill in physic;" she was then supposed to be dead, and was buried; but, in consequence of noises being heard in the coffin, and some other suspicious circumstances, Mr. Pegg, a justice of the peace, was consulted, and "the earth was cast off the coffin," when it was found the woman was not only buried alive, but had given birth to a child, which was found between her knees. "Mr. Abraham Mercer took a certificate out of the parish register book, where it was thus recorded.—"April 20th, 1650, was buried Emma, the wife of Thomas Toplace, who was found delivered of a child, after she had laine two houres in ye grave."

Health of Troops.—At a meeting of the Statistical Society a paper was read on the means of forming and maintaining troops in health, by Assistant-Surgeon Balfour. The inhabitants of towns are the individuals whose position most closely approximates with that in which troops are placed; and the mortality in the prime of life is nearly one-third greater than among the rural population. The deaths among the Foot-guards amount to twenty one-sixteen per thousand annually, and sixteen per thousand may be fairly received as the average of the civil inhabitants of Britain. We thus obtain a standard by which to contrast the loss of life in Britain with that to which our armies are subject when serving in foreign countries. The following is the result of Mr. Balfour's researches:—

Country.	Annual mortality per 1,000.
New South Wales	14·1
Cape of Good Hope	15·5
Nova Scotia and New Brunswick	18
Malta	18 7
Canada, Upper and Lower	20
Gibraltar	22·1
Ionian Islands	28·3
Mauritius	30·5
Bermudas	32·3
St. Helena	35
Tennaserim Provinces	50
Madras Presidency	52
Bombay Presidency	55
Ceylon	57.2
Bengal Presidency	63
Windward and Leeward command	85
Jamaica	143
Bahamas	200
Sierra Leone	483

Surgical Adjuster.—Dr. Jarvis, of Connecticut, United States, has invented a "Surgical Adjuster," the objects of which are, to reduce dislocations, to adjust fractures, and preserve the fractured extremities in apposition during the process of reunion. This machine consists of a brass or other metal case, thirteen and a half inches long, and one and a half inch by half an inch square; the cavity within is divided by a partition running lengthwise, nearly in the middle, thus forming two ways—the one square, into which a rack is to be received,—the other round, in which is a female screw, and into which the male screw of the femur-fork works. Near the other end of the case, and on its outer surface, is a ratchet wheel, the cogs of the pinion wheel matching the cogs of the rack; the shaft of the two wheels terminates in a square *hub*, to be received into a corresponding square sinking at one end of the lever, by which the motive power is effected for making extension and counter-extension. Forks of particular forms, to suit different parts of the body, having threaded shafts, are fixed into the round cavity of the case. Padded rolls of soft material, belts, straps, and a double inclined plane, complete the contrivance.

New optical instrument to facilitate the employment of the speculum uteri.—Mr. Hutchinson, in the *Provincial Medical Journal*, describes a new instrument which he has had constructed to facilitate the employment of the speculum uteri, and which he says, is also well adapted for examining the ear and throat, and can be used in either hand as may be required. It consists of a hollow body, bevelled off at one end, and perforated at the top and bottom. The handle fits into the lower perforation, and is so constructed as to hold a wax taper, which may be elevated and depressed by means of a screw, so as to adjust it to the focus of the internal concave mirror. When a lighted taper, thus adjusted, is introduced into the body of the instrument, the rays of light falling on the mirror are thence reflected towards the opposite or bevelled end; which is lined with a plane mirror, so placed as to again reflect the rays of light, and to throw them directly, through the tube of the speculum, to which the instrument is connected, upon the parts to be examined. The bevelled end of the instrument, together with the plane mirror, is perforated, and an eye-piece inserted, which is thus continuous with the speculum, and enables the observer to see the parts upon which the light is thrown. The eye-piece has a loose cap, into which may be fitted any lens or lenses, of various focal lengths, as may be required.

Physical signs of Endocarditis.—Dr. Durrant in the *Provincial Medical Journal*, mentions the following as the physical signs of endocarditis: —*Inspection.*—Movements of the heart, forcibly and visibly increased; sometimes communicating to the expanded hand the sensation of vibratory thrill. *Auscultation.*—Cardiac pulsations, abrupt, quick, impulsive, often irregular and intermittent, giving rise occasionally, by the force of the impulse, to metallic ringing; in the advanced stages, confused and fluttering. A bellows murmur, concomitant with, and often obscuring one or both sounds of the heart, is seldom absent. *Percussion.*—In slight cases, sonoriety normal. If the heart be much engorged, in consequence of obstructed action, the increase of dulness becomes very apparent.

GOSSIP AND NEWS OF THE WEEK

The French medical journals are making severe complaints against the illicit medical practice entered on more and more by their Pharmaciens. On one side it is alleged they encroach on the Physician, on the other on the grocer.

At a meeting of the Chemical Society a paper was read, "On the Presence of Phosphoric Acid in the Deep-well Water of the London Basin." This is the water from the chalk, below the London clay. It is highly soft and alkaline, and remarkable for the predominance of soda salts over earthy salts; among its solid constituents, as appears from their composition in the case of the well of the Castle street Brewery, Long-acre, which gave from 100 parts—carbonate of soda 11, sulphate of soda 53, chloride of sodium 22, carbonate of lime 11, carbonate of magnesia 2, silica 1, phosphate of lime 0·34, and phosphate of iron 0·43. The author was led to look for phosphoric acid in this water from the extremely rapid growth of green confervæ often observed in it; and he suggests the enquiry, whether the value of some waters for irrigation may not depend upon their containing phosphoric acid, this constituent having been hitherto overlooked in waters.

UNIVERSITY OF ST. ANDREWS.

The half-yearly examinations in medicine at this university were held on the 6th and 7th instant. The following examiners were present and conducted the examinations; viz., Dr. Reid and Arthur Connell, F.R.S.E., Professors of Anatomy and Chemistry in the University, Dr. Robertson, Fellow of the College of Surgeons and Lecturer on Surgery, Edinburgh; Dr. Skae, Fellow of the College of Surgeons and Lecturer on Medical Jurisprudence, Edinburgh; and Dr. Hannay, Professor of the Practice of Physic, Glasgow. The recently appointed Professor of Humanity, William Pyper, L.L.D., was unavoidably absent, but the examinations in the Latin language were proceeded with as usual. The following gentlemen, after a minute and scrupulous examination in all the departments of medicine, in the presence of the Senatus Academicus were recommended by the Board of Examiners to the Senate, as being in every respect qualified to undertake the full and enlightened discharge of their professional duties, and worthy to be promoted to the degree of Doctor of Physic. The degree was accordingly conferred by the Rector, in the large hall of the public library of the university, in the presence of the examiners, the senators, and the public. Nine other candidates offered themselves for the degree, three of whom withdrew their names during the course of the examinations, and left the seat of the University without undergoing the ordeal, and the remaining six were rejected.

Of Scotland.

Balfour, George, Edinburgh
Brodie, David, Surgeon
Buchanan, John Gourlay, Surgeon, Edinburgh

A special board will be held on Tuesday, July 1st., for the examination of candidates qualified according to the regulations of the University, and who are anxious to possess a physician's degree before the passing the new Medical Bill.

No. 297 **SUMMARY.** MAY 31.

COURSE OF LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

Delivered by C. J. B. WILLIAMS, M.D., F.R.S., Professor of the Practice of Medicine, and of Clinical Medicine at University College.

WE now come to speak of hydrophobia. This is a most terrible disease; it is the result of a poisonous influence, derived from the canine species, and is communicable by inoculation. There are various periods assigned for the operation of the poison, and from forty days to eighteen months, or even in some instances two years, elapse after the inoculation before the symptoms of hydrophobia manifest themselves. The symptoms at first are feverishness, pain, torpor, and numbness, extending over the whole limb; sometimes swelling and redness. The pain is in the course of the nerves, seeming to show that the poisonous influence is not conveyed into the system, but that the irritation is confined to the nerves. The local symptoms may last from two to six days before the hydrophobic symptoms declare themselves; then there is a remarkable anxiety of the feelings depicted in the countenance, frequent rigors, disgust of food, and some difficulty in swallowing, particularly liquid food. There are stiffness and pain at the root of the tongue, and there is a peculiar spasm of the throat, which appears to be a spasm in the pharynx in the first instance, accompanied by convulsions of the muscles concerned in the act of swallowing. The very idea of swallowing, the sight or sound of liquid, produces violent spasms of those muscles, and sometimes the sight of anything shining which bears a resemblance to liquid seems to excite it. There is generally a copious flow of a very viscid saliva. The spasm extends to the glottis and causes difficulty of breathing. It extends, too, to the whole trunk, and as the disease is more marked, spasmodic actions are not only excited by the idea of swallowing, but by every sudden impression on the incident nerves in various parts of the system; thus, for instance, sudden noises, flashes of light, blowing of draughts of air on the surface, or even the bed clothes, will sometimes excite the convulsive movements. There is a terrible state of restlessness which is distressing in the extreme, yet the mind is often not much affected. Sometimes there is delirium, but it is only occasional; sometimes the patient will be quite rational at intervals, but the mind is depressed with horror at the approaching attacks. The pulse is very irregular and rapid, and appears soon to become exhausted in the manner in which it occurs in tetanus, and the convulsions prove fatal in twenty-four hours, but sometimes not till the fourth day. It is the general rule that in hydrophobia the spasm is excited by the idea or sight of liquids, but there are some instances in which it is not so, and very often there is a catching of the breath, which is a distinct sign that the spasm appears to affect the diaphragm. The nerves that are the chief instruments of these convulsions appear to be the fifth nerve—the trifacial,—the eighth in connection with the function of respiration, and the ninth, which, together with the other, is connected with the function of deglutition. The spinal accessory, or the phrenic nerve, and the cervical spinal nerves appear to be also complicated. On *post mortem* examination there is very little trace of the affection. The spinal cord exhibits no particular change. The pharynx and stomach usually present changes, and exhibit a considerably increased vascularity, and a great increase of slime and mucus; but this is quite uncertain, and when it does occur it is the effect of irritation of the membranes. The disease is essentially a nervous disease. We are much in the dark as to the mode of treatment for this disease. The last remedy proposed for it, which has in one or two instances been of service, is Indian hemp—the remedy employed for tetanus. It appears to have a peculiar action, and to stimulate the excito-motory function, and maintain the tone of the muscles. Whether that tonicity is derived from the spinal cord is a question that physiologists have not decided. Opium, on the other hand, diminishes the excito-motory action, as do also many other agents; and as to the various other remedies that have been proposed they have all proved unsuccessful, though more time has been expended in their trial than the importance of the disease merits, considering its rare occurrence.

Neuralgia is a local affection of the nerves, and constitutes the familiar disease known as tic douloureux. We have found that the motor nerves or their centres are irritated as in tetanus, and likewise we have found that inflammation affecting these nerves and their centres will cause spasm. The same observations will apply to the sentient nerves, which, when irritated, have their function exalted for a time, and with this exaltation there are pains of a peculiar character. They may be irritated by mechanical influence, by determination of blood, or by inflammation. We have met already with one form of neuralgia in the varieties of rheumatism, and have adverted to rheumatic neuralgia. It is of the inflammatory kind, but sometimes severe neuralgic pains in the course of the nerves arise quite independently of rheumatism. We have met with neuralgic affections of the pleura, constituting sternalgia or pleurodynia; and nervous affections of the heart, or angina, and of the stomach, or gastrodynia; and these may occur in connection with disordered function of the different organs, or diseased structure. But in nervous subjects various neuralgic affections occur, sometimes independently of other disease. There are violent neuralgic pains, and sometimes to such a degree as to give an extreme sensibility to a particular organ. The term irritability has been wrongly applied to this, which should more properly be termed sensitive. There are other instances in which the integuments exhibit excessive sensibility to touch, particularly in females and nervous subjects, the slightest touch causing them to cry out. In the worst cases the pain is sudden and excruciating, and is compared by the sufferer to burning, tearing, or pinching by hot irons. It comes in severe twitches like electric shocks, these twitches being excited by motion, touch, cold or heat, blowing the nose, coughing or sneezing, and are sometimes relieved by strong pressure. The tears flow freely and the saliva is copious. The attack may last several minutes, and in the worst cases it goes on for several hours; it comes on in paroxysms, recurring at various intervals. It occurs in the face and head, and is usually confined to one side, affecting one branch of nerves; the *supra-orbital* nerve, and the various branches of the *tri-facial* nerve are most commonly affected. There are spasms accompanying it—spasmodic twiches and convulsive motions which depend on the motor branch of the fifth. Sometimes the *portio dura* is also affected, and the muscles it supplies are thrown into violent action. The tri-facial seems to be the chief seat of the disease. In some cases it can be traced to some mechanical injury to one of the branches of the nerve, transmitting the irritation to the other branches, and other parts of the same branch, and in this respect there is a resemblance between the irritation of neuralgia propagated backwards to the centre of the nerve, and reflected back again to its various branches. This resembles the irritation in traumatic tetanus, where it begins at a distant extremity, and is transmitted up to the spinal centre, and thence throughout the various parts of the body. In many cases after amputation of the arm the seat of the pain is referred to a distant part from that amputated, as if the nerve of the arm had not been cut off: a man who had his thumb cut off complained of violent pain in his finger; and another patient who had a bad stump amputated, cried out, "Oh my finger," though he had lost the finger of that arm some years before. In many cases of neuralgia no mechanical cause is to be found. In some bad cases there have been found ecchymoses, and in others nothing at all. Neuralgia comes on like intermittent fever, periodically; in many cases it occurs in connexion with marked disorder of the digestive organs, and in others, with disorder of the urinary organs, and a disposition to the formation of lithic acid; or, as Dr. Prout believes, of oxalic acid. In a few cases there have been found diseases of the nervous centres. Neuralgic pains are extremely common in nervous subjects, without remaining long enough to become local; but neuralgia, in the most severe form of tic douloureux, is perhaps the most agonizing complaint a person can experience; the pain is so violent as to occupy, as it were, the very seat and centre of sensation.

Treatment.—If the cause of the irritation can be found, the sooner it is removed the better. Disorder of the functions, and of the digestive organs should be traced out and treated accordingly. Where there are symptoms of inflammation, and where the disease has arisen from cold, local antiphlogistic treatment may be useful. Where there are no such signs, the nervous sensibility should be treated. For this, narcotics or anodynes, to reduce the nervous sensibility, and metallic tonics are indicated. The most proper narcotics and anodynes are, aconite, belladonna, stramonium, Indian hemp, and opium. These remedies may be applied externally or internally. Creosote has been effectual in relieving tooth-ache, which is obviously a neuralgic affection. Counter irritants, too, are sometimes of use, and strong liquor ammoniæ has caused a remarkable improvement in neuralgic affections. Aconite or veratria well rubbed in seems to act as a counter irritant. These sometimes succeed, and occasionally fail: they have been tried in all their various shapes in bad

cases, and it is remarkable how they have succeeded in different cases. Another very useful remedy is the acetous extract of colchicum, applied in combination with belladonna to the part. It has afforded more relief than any remedy, owing probably to the disease having some connexion with rheumatism. Of the more permanent remedies, the metallic tonics, those which deaden the nervous sensibility, carbonate of iron in large doses, appears to be the best; but it very often fails. Its efficacy is only temporary, and it seems to be most adapted to persons of weakly constitution—anæmic subjects. Nitrate of silver, in some local affections, such as excessive sensibility of the eye, and of the stomach, seems to have some title to be classed along with the other remedies. The vapour bath, the hot douche, and cold affusion have succeeded. In cases of failure of other remedies, the expedient of removing the nerve has been resorted to, and in very few instances it has produced relief, but it has been only temporary. Where the disease is intermittent or periodic, there is much more hope of curing it; and where it has been produced by a malarious influence it will yield to remedies; to quinine in large doses, as much as a scruple three times a day.

There is an affection called *spinal irritation*, a term very vaguely used—in fact, spinal irritation is now becoming synonymous with *hysteria*. A much better term is exalted sensibility of the excito-motory function, connected with a distinct spinal disorder, as for instance, in connexion with spinal distortions. Disease of the spinal column seems to be connected with the more temporary disorders of the spinal cord, apparently arising from congestion or irritation; where, for instance, in very nervous subjects, inflammation occurs in any part of the general system for a considerable length of time, the irritation becomes transferred from that part, after a time, through the incident nerves to the spinal column, producing increased sensibility in the other parts supplied by branches of the nerves from that part of the spinal cord. Take for example, a person affected with a violent pain in the stomach or upper intestines; he is perfectly free at the beginning from any spinal affection, and if the inflammatory symptoms are removed, he will cease to complain of any pain in the region of the stomach, but pain felt about the middle or lower dorsal vertebræ when the spinous process is struck. This affection apparently has its origin in visceral disease. The irritation continuing is transferred to the spine; when the original disease is removed, it causes tenderness of the part. There is not tenderness of the spinal marrow itself, but there is excessive tenderness of the nerves distributed in the neighbourhood of the spinous process. Neuralgic pains are also deeply seated; they appear to have their origin in parts connected with the spine, and this is owing to the long-continued increased vascularity or determination of blood to these parts. Now the treatment of these affections may be local; local depletion and counter irritation, a few leeches or cupping glasses over the region of the spine, and dry cupping often answer extremely well. Purgatives, too, have had a remarkable effect in relieving irritation of the spinal cord. It may be necessary to use narcotics, more particularly those that act on the nervous system; belladonna, stramonium, and hydrocyanic acid. Tonics are to be regarded as the most curative measures, to prevent the disease continuing; cold sponging with salt water or vinegar once or twice a day, alternated with friction, is of great advantage in these neuralgic affections.

The next subject to be considered is *hysteria*. This is a disease of great importance, and the diseases connected with it are so numerous from their frequency, that we cannot pass it over so lightly as it has been hitherto; it is a great bugbear from its intractability. Here is something to try to find out what it is, and to lay down some rules by which to deal with it. Under the term hysteria we may include the symptoms of almost every disease flesh is heir to. What are called symptoms of disease depend on derangement of the vital properties. The various organs of the body are more or less under the influence of the nervous system, and disorder of this system is capable of so modifying these properties as to produce in almost everybody a combination of the symptoms of disease. This is the truth of the whole matter. Why does hysteria, in its widest terms, ape so many diseases? It is because the nervous system, of which hysteria is nothing more than a representative, influences every vital property in the body. The most common, and the most permanent effects of hysteria are the various modifications of the nervous functions, and those functions which are in immediate relation to the nervous functions; thus, the symptoms generally called hysterical are those of altered volition, disordered volition, disordered sensation, excito motion, and disorders of every involuntary motion, and of every organic function under the influence of the nerves, the excretions, and the secretions. But some of the most permanent of these symptoms are what are commonly called, nervous or convulsive affections, or sensitive affections. Cullen, and most others, have applied the term hysteria especially to a combination of nervous symptoms; and what are called hysterical fits exhibit the complications of these in a most remarkable degree. Hysterical fits consist of a continuation of sensitive convulsive actions and moral emotions, coming on by laughing and crying; connected with the sensations referred to is a lump in the throat, *globus hystericus*, and *clavus hystericus*, the convulsions extending to the whole body. But those which are called more generally regular hysterics, are more obviously a distinct form, and constitute a very small portion of the most common hysterical affections, and may be classed together. Another great reason of the disease being misunderstood, is the unfortunate name that has been given to hysteria, connecting it with the womb. It is quite true that these various nervous affections occur chiefly in females, and often in connexion with disorder of the uterine system. In many cases it is quite certain the uterus is not in fault, in other cases where it is so, it is only secondary, and, in the majority of affections to which the term hysteria is applied, it is to be considered as a disorder of the nervous system itself, independently of any other part. It occurs in females because they are more nervous, more sensitive, more mobile, and have a greater amount of excito-momentors. Hysterical affections occur during the uterine period, and why? Because the health is apt to be disordered by the uterine function, the sensibility failing in connexion with this. It is at this period of female life that the body and mind are most sensitive; but hysterical disorders are not peculiar to this age, for children affected with chorea, become in after life, subject to hysteria. Again, at the termination of the period of uterine action, when menstruation ceases, the female does not cease to be nervous and hysterical. The disease is more marked in old and nervous females than it is in young ones. It is not peculiar to the sex; men and boys sometimes become subject to hysterical affections; those who lead a sedentary life and those who study hard to the exclusion of bodily exertion; and to these may be added effeminate habits, there being in these cases more development of the nervous, than of the vascular properties of the system, and of the muscular powers. Hysterical symptoms may also be excited by circumstances that produce very strong moral emotions acting on the nervous system. They are also excited in cases where the muscular system has been reduced by any particular cause, or excessive evacuations, and thus weakness, in general terms, becomes synonymous with nervousness.

COURSE OF LECTURES ON SKIN DISEASES,

By D. J. Corrigan, M.D., Physician to the Whitworth, Hardwick and Richmond Hospital, Lecturer in the Dublin School of Medicine, &c.

Gentlemen,—The period which is most critical to a patient in small pox is about the eighth or tenth day. If the pustules, which were previously full and tense, become flaccid or shrunk, or if they become confluent and run one into another, attended with a weak and feeble pulse, with other signs of debility, it is a period of great danger. This flaccidity of the pustules is only one (among the other) symptoms of the state of collapse which has supervened. When the skin becomes contracted, and the parts beneath lessened in size, you will pursue the same line of treatment which has been pointed out for your guidance in typhus fever under similar circumstances, namely, the exhibition of ammonia, bark, camphor, musk, &c., wine, and small quantities of rich jellies, frequently repeated, for under the circumstances just now detailed, you must bear in mind, that the disease before you is nothing but typhus fever conjoined with small pox. About the same period comes on also another phase of the disorder, highly dangerous to your patient. On the eighth or ninth day a slight swelling of the face comes on; this arises from slight effusion into the cellular tissue, and is afterwards removed; so far this is a good sign. The parotid and salivary glands become engaged, and pour out an increased quantity of saliva; this also is a favourable sign; but along with these signs, in some cases, if you examine the carotids you will find them beating violently; and along with this you have sleeplessness, which if allowed to continue, must end in delirium, coma and death. You might, from witnessing this violent action of the carotids at first sight, be led to look upon such a case as one calling for the adoption of depletive measures, but it is not so. Depletion here would be wrong. Examine the heart, you will find its action, though frequent, debilitated, and when you feel the pulse at the wrist, you find it quick, and very compressible. Here, as in other fevers, your grand object should be to remove that functional lesion of innervation which prevents sleep. This is the stage of small pox where opium becomes a remedy of incalculable utility. A large dose of opium given at this juncture produces sleep, after which the progress of the cure is generally favourable. The above state of things in my opinion is one of sympathetic nervous irritation, induced by the presence of a large number of small abscesses over the body, and this seemingly violent action of the carotids will be found to be more the palpitation of debility than the sthenic action of inflammation.

Varicella;—Swine-pox, chicken-pox, modified small-pox, by which ever of these you chose to call it, comes next. All these varieties of pock, in my opinion, should not be separated, but should form one class. I think that much unnecessary sub-division has been made among them by systematic writers, who seem to forget that they are all modifications of the same disease, small pox, presenting the same characters, and calling for the same treatment. Some years ago, when small pox prevailed to a much greater extent than at present, cases of this disease were very rife; but latterly, owing to the great progress of vaccination, neither it, nor small pox are so much to be met with. Authors writing on small pox, and its modified variety, have been at pains to lay down characteristics, which would enable us to distinguish between them. For this purpose, some have spoken of the premonitory fever, as furnishing a distinctive mark. Others have spoken of the crystalline, or pearly appearance of the vesicles (this has been termed bird pox); but I think, none of these furnish us with a satisfactory test between them. The fever in varicella is just as severe as in variola; the pains in the back, and vomiting, are just as urgent; and as for the crystalline appearance of the vesicle, that I look upon only, as an *incident*, not an *essential* of the disease. It is attaching importance greater than it merits, to every trifling deviation from what is supposed to be the regular phase of this disease, that has led to the formation of so many unnecessary varieties. The only criterion which can be depended upon, as furnishing us with a means of judging between them, is the irregularity of the eruption in varicella. In this drawing (sending it round), made from a patient under our care at the Whitworth Hospital, you have an opportunity of seeing this irregularity of appearance. In one part, you will see the vesicles dry, and scabbed over; while in another quarter, they are but appearing; and here and there, through the whole, you perceive scattered, these crystalline vesicles, termed bird pox. A circumstance occurred some years ago in Edinburgh, which, in my mind, places the

identity of small pock and chicken pock beyond all doubt. It is detailed in the *Edinburgh Medical and Surgical Journal*, the exact year when it appeared, I do not remember; it may be perhaps three or four years since; at any rate, a reference to the series for a few years back will enable you to discover it. At the time I speak of, modified small pox made its appearance at Heriot's Hospital, in Edinburgh. A very interesting account of it was drawn up by the surgeon of the Institution, which was published, as already remarked, in the *Med. and Surg. Journal*. This Heriot's Hospital is a charitable institution, somewhat like our own Blue-Coat Hospital, and contained at that time, about ninety or one hundred boys; of these, all had been previously vaccinated, yet among all, with the exception of some three or four, did the disease run. None of these boys fell victims to it; the only person who was carried off, was one of the masters, and he had been previously vaccinated. Of the fact of the disease having been modified small pox, I think there can be no doubt, as the infection spread among them from the porter's son, who had died of confluent small pox. Here we find vaccination not acting as a preventive of small pox; but we find it creating a power almost equal, and next to that of a preventive; we find it exciting such a controlling power over the disease, as to reduce the mortality to one per cent, when previously to its introduction, it had averaged from nine to ten per cent. In this drawing, which I have already exhibited to you, we have modified small pox appearing, though the arm presents the regular vaccine cicatrix. From the fact which I have mentioned, of the appearance of modified small pox at Heriot's Hospital, I think that there cannot be a shadow of doubt cast upon the identity of small pox and varicella.

I had almost forgotten to speak of a subject closely connected indeed with the treatment of small-pox, and its modified variety; namely, the pits which are left after the disease. For many years past, in the extensive experience of small pox which the Whitworth Hospital has afforded me, I can confidently affirm, that a single badly marked case has not left it. When I speak of the experience afforded me by the Whitworth Hospital, I do so from a feeling of consciousness that no other medical man in the city or in Ireland, with the exception of my colleagues at that institution, can have had or have had such opportunity as I had of studying this disease. The fact of more cases of small pox having been admitted there than in all the other hospitals in Ireland collectively, will bear me out in my assertion. Some years ago when small pox prevailed here as an epidemic (and let me tell you that when it does appear, it is an epidemic) I was struck by the remarkable fact, that on no other parts of the body save the face and hands, were pockpits discernible upon the convalescence of the patients; struck with this fact, and remarking that the axilla and groins in particular shared in this immunity, I began to reflect upon its cause. It could not be that these latter parts possessed any peculiarity of texture which rendered them as tissues different from the face and hands, nor could the looseness of cellular tissue in the groin or axilla be the cause of this exemption from marks, as we find these marks in abundance about the eyelids, which are possessed of as lax a cellular tissue as either the axilla or groin. Conceiving this immunity to depend, not upon any structural difference existing between those parts of the body which were free from marks, and others which were deeply seamed, I considered it to be due to the natural moisture of these parts, keeping the pustules soft, and preventing them from falling off prematurely, before a new skin was formed underneath. Acting on this idea, I determined to apply something over the entire face, which should completely protect the pustules, and prevent their exposure to irritation of any sort, until they were detached by the formation of new skin underneath. For this purpose the application which suggested itself to me as likely to answer best, was lead plaster, melted with as much almond oil, as would allow the compound when moderately heated, to be spread over the face with a camel-hair pencil, and when dry to form a perfect mask of consistent firmness. This application can only act beneficially on the principle of oiled silk dressing, namely preventing prespiration from the pustules, and preserving them free from irritation, until they become detached by the natural process of the formation of new skin underneath.

This mask is to be allowed to remain on, until the detachment of the scabs by the new skin brings it away with them. It looks to be sure very hideous for a few days, but I think that exemption from permanent personal deformity is cheaply purchased at the price of an ugly face for some short space of time. The following case will I think illustrate both the utility of the application, and the correctness of the idea, from which its employment originated. I had been attending a young lady ill of small-pox. Her face had been coated over with this application, from the time the pustules were fully formed.* The greatest part of these pustules had been detached from the face without the slightest deformity having been produced. None of the mask remained, save a small portion covering part of the nose. This I cautioned her against interfering with, advising her to allow it to be detached naturally. She became impatient, disregarded my injunctions, picked at it until she removed it, but ulceration of the part set in accompanied with inflammation of the surrounding skin so violent as scarcely to be controlled, before ulceration had extended to a much greater distance, than the part first attacked. In consequence of her own folly, this part was very deeply marked, while the remainder of the face preserved its usual smoothness.

It has been recommended to destroy the pustules when they first appear by cauterisation with nitrate of silver, and this method it is said prevents all deformity. This I have never tried. Perhaps it is the great and uniform success, which has invariably attended the adoption of the preventive means which I have just detailed, that has made me unwilling to change it for another and more doubtful means. This is the remedy which from extensive personal experience of its efficacy, I would be inclined to recommend to you for adoption in your future professional career. From the time the small pox pustules are fully formed, coat them over with this application and allow it to remain undisturbed, until the formation of new skin underneath disturbs it. By adopting it, I can confidently promise you the gratification of sparing your patients the grievous amount of deformity, which the numerous cicatrices of small pox must otherwise inevitably produce. Were I inclined, I could enter at much greater length into the nature of the different varieties of small pox and its modifications, but this I think would be but an unnecessary wasting of your time. I shall therefore dismiss these subjects, contenting myself with having called your attention to those points connected with each disease on which, as I conceive, I have given you some knowledge, which you would not find detailed in works on these subjects.

The next disease *ecthyma*, is one which you will find much easier to understand from drawings than from any verbal description which I could give you. Here, in one of Alibert's plates (handing one round), you have an opportunity of seeing it as it appears on the extremities. You find it to consist of a number of pustules, which become covered with a dark brown soft scab, each pustule a phlyzacious one, and surrounded with a patch of inflamed skin to some extent outside it. This pustular eruption generally makes its appearance in broken-down drunkards, and persons who have injured their constitution by excesses of every sort, though you sometimes find it in persons who have never been addicted to dissipation, but, wherever it comes, it invariably is a sign of a depraved habit of body. I shall not detain you by entering into any minutiæ concerning this disease; in reality, the matter does not require it; the only thing necessary is to remove all traces of irritation and inflammation from around the seat of the eruption, then poultice it until the scabs come off, and dress the ulcers with some sedative application, such as the ung. cerussæ albæ, which may afterwards be changed for a more stimulating dressing of any kind which you may deem proper. Along with these local means you must not lose sight of the principal point of treatment, namely, supporting the constitution by the very best means possible. Such are the administration of tonics, but above all, by ordering for your patient that diet, which, in the smallest bulk, contains the greatest nutriment; animal food, fully and freely given according to the strength of your debilitated patient's digestion.

The next disease is, *acne*, one which should not be classed among the pustules at all. In this disease the sebaceous follicles of the face become filled with their peculiar secretion, and the action of the skin becomes enfeebled so as not to be able to get rid of this superabundance of secretion. This is Acne Simplex. None of you will fail in recognising this drawing (holding it up); it is a specimen of disease which you do not meet with so often now as before; it is, I am sure, familiar to all of you under the name of the "grog blossom;" or, drunkard's nose. In this variety of acne, the skin to some extent around the neighbourhood of the follicles, becomes inflamed and of a dusky red, giving to the face the peculiar appearance which it assumes in this disease. Acne simplex is a disease principally affecting persons about the period of puberty, and is often a source of great annoyance to young ladies, and young gentlemen who wish to look lady-like, and who, for this laudable purpose, take very great pains about their person. If they but keep themselves easy for a year or two, the disease (if you can call such a trifling affection by so great a name) will disappear without the least aid from the doctor. However, as they will not keep easy, but will come to consult you, you must know what is best for its removal; for this purpose I do not know anything better than a lotion of hyd. bichlor. in the proportion of one scruple to one ounce of aqua distillata. This applied to the face two or three times a day for a few days, produces in the skin of the face a more vigorous state of circulation, approaching very closely to a state of inflammation; the cutis vera is stimulated, the scarf skin is thrown off and replaced by a new layer, while the distended follicles share in the vigour which has been excited, and resume their natural size. With regard to the other variety, the use of alterative medicines, such as sarsaparilla, with liquor potassæ, and Harrogate water, &c., will quickly remove it, provided you can persuade your patient to refrain from what has induced it, but *that* I promise you will not be the easiest part of the case.

Mentagra comes next: this disease attacks the chin, whence the name; though sycosis would be a more proper term. It sometimes attacks the scalp, and descends along the side of the face to the chin. On the chin it commences in phlyzacious pustules, which quickly communicate—that is, the areola of inflammation surrounding the pustule, quickly spreads to the next, and so on, until the whole surface, not studded with these painful tubercles, presents one continuous sheet of redness, and along with this eruption on the chin, it is not uncommon to see a few of these pustules, as large almost as small boils, make their appearance down the neck. If the pustules, after they have appeared some days, be cut into or broken, and the contents pressed out, a tough, stringy, white matter is seen making its way from each; but if, on the contrary, they are allowed to remain unirritated and quiet, they very shortly put on the appearance of one immense scab; this, with a beard of a fortnight, three weeks, or a month's growth even, protruding through, must, and does give the face, a frightful and hideous expression. But though seemingly frightful, and dangerous, it is, however, a disease which need not alarm your fears for the patient. From the angry appearance which these pustules present when the scab is removed, one, unaware of their real nature, might suppose the case to be one of cancerous ulceration; from this you will be able to distinguish it at once, by being able to discern each individual pustule —by the freedom from lancinating pain, and by the character of the discharge, which is thick, and ropy, or curdy, and flaky, while that of cancer, is a thin, and horribly fœtid sanies; and lastly, by the appearance of health which the countenance presents in contradistinction to the

peculiar hollow cheek, with its hectic circle, which invariably attends upon cancerous ulceration. In this drawing, taken from a patient under our care in the Whitworth (Pat Murphy, ætat. forty-three), you have a capital representation of the appearance this disease puts on when it attacks the chin. Here is a plate of Alibert's—also very well done. Either of these, if you keep them in memory, cannot fail to remind you of its real nature, if at any time hereafter you should meet with a case of this disease and be doubtful of its nature. Sycosis attacking the scalp assumes another phase. The pustules here appear in a circular form; the inflammation here, as on the chin, extends along the surface, from the areola of one pustule to that of the next, and so on, until the circle is complete. Here the inflammation extends to parts below the surface, and if you press with your finger over a patch of this sort it will convey to you the sensation of pus having been formed beneath, or as if the part pressed upon covered a piece of dead bone. Neither of these is the case: this sensation arises from the effusion of lymph beneath the cutis vera, owing to the progress of inflammation in this tissue. All you have to do in such a case, is to make a crucial incision and relieve the distended scalp, when this sensation immediately vanishes. It has been proposed to apply this line of treatment, by incision, to the pustules on the chin; but such a proceeding would be *barbarous* and unnecessarily cruel. The advocates of this line of treatment seem to forget, or are really ignorant of, the motives which guide us in the use of the knife in sycosis capillitii. The knife was used there, not to relieve the essential of the disease, or more correctly speaking the disease itself, it was used for the relief of incident in the disease: namely, to prevent the formation of matter under the aponeurosis of the occipito-frontalis muscle. Such a motive does not call for its employment when the disease is situated upon the chin; and if used here, would be, as I have already observed, unnecessarily cruel. All that you need do is as follows. Poultice the parts affected for whatever length of time it may take to detach the scabs; when these come off, apply the cerussa ointment, or some such soothing application; do this until all the inflammation has gone down, when you may venture to apply a stimulant of moderate strength. The administration of purgative medicines along with the means just mentioned, will generally remove the disease in three weeks or a month, though it very often takes two and three months before it is quite cured. This is the treatment which I would have you adopt in the different varieties of this affection —bearing in mind, that though the use of the scalpel may be necessary in relieving an incidental complication when sycosis attacks the scalp, it is not by any means called for when the same disease attacks the chin.

LECTURES ON PHYSIOLOGICAL ANATOMY, THE SPECIAL PHYSIOLOGY OF MAN, AND ON THE ANATOMY OF TISSUES -MORBID AND HEALTHY,

By Dr. Knox, F.R.S.E., F.R.C.S.E., Corresponding Member of the French Academy of Medicine, and Lecturer on Anatomy and Physiology, &c. &c.

LECTURE VII.

Bones of the Cranium and Face.

Leaving for a time those comparatively speculative subjects we have lately discussed together, I proceed now with the physiological history of the cranial bones. I shall suppose, or rather take for granted, that the student is perfectly master of the common elementary details of structure, without a knowledge of which he neither can nor ought to proceed. The parietal bones from their great size in man are especially cranial bones: they are moulded on a large extent of cerebral surface, presenting however but comparatively few varieties. These may be summed up briefly as follows. 1° The presence or absence of the osseous groove at the inferior and posterior angle. 2° Crests inferiorly and superiorly, already spoken of as continuous with those on the frontal bone; each bone may have two, and there is sometimes a mesial crest along the line of the coronal suture. 3° They occasionally but rarely overlap the frontal bones a little, but are much more frequently over-lapped by the occipital. 4° Varying in thickness and presenting deep elongated cavities on their outer surface, symmetrical, that is one on each bone. These deep cavities exist only in the outer table and diploe, there being no corresponding elevation on the inner table. Thus the brain does not in any way suffer by the formation of such depressions as those I now speak of. 5° The groove for containing the superior longitudinal sinus is occasionally formed by one parietal only. 6° The depressions for those singular bodies, the so called glands of Pacchioni may extend nearly through both tables. 7° The existence of a suture more or less vertical, oblique, or longitudinal, dividing the bone into two, an anterior and posterior, or a superior and inferior, and involving both tables, or only one. Of this variety, I have never met with a specimen.

Spheno-Occipital Bones—Occipital Portion.—Every anatomist knows, that these bones form but one in the adult head, but that, for the sake of facility of description, they are spoken of as two. The occipital bone is the one which best proves the analogy between the cranial and the spinal vertebræ; the basilar process representing the body of the vertebra, and the condyles the articular processes, as they really are. The recti capitis postici are enlarged inter-spinal muscles, and the recti laterales are evidently inter-transverse. Upon the basilar process of the bone rests the medulla oblongata, a continuation, in fact, of the spinal marrow. These analogies need not be traced further at present. The occipital bone presents great varieties as to form and development; sometimes projecting in an extraordinary way, especially in the Scandinavian head; the upper angle remains sometimes a separate bone, or there are two at this angle. Supernumerary bones, which do not seem to be so frequent in the dark races of men, occasionally abound in the line of the occipito-parietal suture. The foramen magnum is seldom symmetrical, and the same remark applies to the condyles. Upon the whole, however, these and other varieties occasionally observed in this bone, do not amount to much; let us pass on to the other portion, usually called the *sphenoid bone*.

The body of this bone represents the body of a vertebra. In it are the sphenoidal sinuses, whose uses cannot even be guessed at. They form a part of a system, no doubt, whose meaning must be sought for in comparative anatomy. In the sella turcica, or pituitary fossa of this bone, rests that mysterious structure—the pituitary body, whose physiology is still to be discovered; by some supposed to be the commencement of the sympathetic system of nerves, but in respect of which nothing certain is known, but the constancy of its presence. Notwithstanding the great number of sphenoid bones I have examined, I have not met with any very remarkable, or particularly meriting notice. In the fœtus and child it is composed of five separate bones, which afterwards consolidate. In many animals, a different arrangement takes place, and in the adult the bone may be found divided into an anterior and posterior sphenoid.

The Temporal Bones:—Two in number, placed on each side of the cranium; form also a considerable portion of its base. The elementary anatomy of these bones is easy of acquisition by the industrious student, but in order permanently to fix the facts in his mind, he must repeat them daily for a considerable time. No bones have more exercised the patience of the comparative and philosophic anatomist than the temporal, containing one of the organs of sense, and other bones, within one of their cavities; formed of several portions in the human fœtus and child, of which some portions, or perhaps even all may remain separate bones throughout the whole period of the animal's existence, and of these portions, thus maintaining an independant form and position, some may be employed for other purposes than merely completing the walls of the cranium, and contributing so small a share in the formation of the face, as they do in man; these considerations, with many others, have brought these bones prominently before the physiological anatomist, ever since the time when correct transcendental anatomy was first unfolded by Frank and Goethe. With speculations so deep, and yet so interesting, we have nothing to do here; this is a course of human physiology, and to human structures, in as far as I possibly can, it is my intention to adhere.

The mastoid process, which is so small in youth, grows with our years; it becomes sometimes slightly eburneous at the extremity, and I have fancied it be largest in the Scandinavian crania. The cells contained within it are also said to vary much, which no doubt they do, although I have not especially observed this. The openings of the canals, and the canals themselves, which are occupied by the minute branches of nerves, the one arising from the petrous ganglion of the glosso-pharyngeal nerve; the other from the nervus vagus passing into the inferior portion of the canal of Fallopius, and thence supposed to proceed to the external ear;* these openings, and the osseous canals they lead to, should be pointed out to the student.

The rocky part of the temporal is extremely hard and unlike the rest of the osseous tissue; on its general nature M. de Blainville founds his opinion, that it is not strictly bone, but a modification of the osseous tissue, analogous to the other osseous deposits, which in birds are found surrounding the sclerotic. These views are highly philosophic, but require confirmation as to details; comparative anatomy best supports the idea. In the human fœtus the temporal bone has an entirely different form from what it afterwards acquires; the squamous part is entirely separate from the rocky portion; the external auditory canal instead of forming a large osseous tube, is simply a bony circle with a groove, into which is inserted the membrana tympani; the mastoid portion is scarcely visible; the rocky part being incomplete, leaves exposed the outline of the vestibule and the semi-circular canals.

Of minute differences little is known. On looking into the meatus externus, it is easy in some specimens to see both fenestræ; whilst in others, the fenestra rotunda, or tympanic opening of the cochlea looks so much backwards, as in carnivorous animals, as to be nearly invisible.

Ethmoid Bone.—Singularly formed, and unlike every other bone in the body, to which it bears no resemblance; placed also mesially, and united at least mechanically, if not physiologically, with a nerve whose functions may be clear enough, but whose relations to the brain and nervous system are by no means well understood. Independant of great varieties in breadth, depth, and general form, we find in some specimens an attempt, more or less perfect, to form three turbinated processes instead of two, the usual number, thus adding to the meatuses found on this wall of the nostril. The learned authors of the *Encyclopedic Anatomique* think this a deception, ascribing the appearance of a third turbinated process above the others to a fold of mucous membrane prolonging the bone in that direction. Now, without referring again to the specimens on which I have seen a third turbinated process belonging to each ethmoid, I feel confident that it sometimes exists altogether independent of the mucous membrane, as I have seen it in the skeleton. The fold of mucous membrane alluded to by Sœmmering and the Webers, may, no doubt, add to its strength, length, and shape, but it did not altogether form it in the specimens I speak of. Of these prolonged folds of membrane connected with the true and false turbinated bones, I shall speak more at length when describing the true turbinated bones; in man they are rudimentary structures; in the horse they are connected with and form important organs: the development of an additional cartilage, and a vestibular cavity placed in front of the great nasal chambers, of great importance, no

* I saw this branch in 1821, and believed then, as I do still, that it influences the functions of the portio dura.

doubt, to the economy and well-being of the animal.†

The orbitar plate of the ethmoid is sometimes divided into two portions by a slightly oblique suture, and when the os unguis is very small it supplies its deficiency. In infancy, this bone is solid and cartilaginous, becoming only gradually developed; the cribriform plate, however, appears larger in the child than in the adult. When very narrow, it influences of course, the position of the eyes, causing them to approach each other—the physiognomy becomes peculiar, and the person partakes more or less of the buffoon.

Bones of the Face.—If we include with the bones of the face, the teeth, few parts of the skeleton furnish a greater number of physiological considerations, based on the physical structure, and intimately connected with it. By physical structure, I here mean the structures which may readily enough be made out by mere descriptive anatomy. I shall commence with the superior maxillary bone or bones, requesting the student to remember how many interesting and important soft structures are found here, on the face, most of which have intimate relations with the skeleton or frame-work destined to support them. Besides several of the organs of sense, the commencement of the respiratory and digestive tubes are placed here; and in the distribution of muscles, nerves, and integument we naturally look for that beauty of countenance, which, when in perfection, enchants the world.

The superior maxillary bones:—their descriptive anatomy being already understood by the student, we may now inquire into its minute history. At birth these bones present all the prominent parts of their anatomy sufficiently well made out; the lachrymal portion of the ascending process with its lachrymal groove is frequently more or less separated from the ascending process by a groove, evidently the vestiges of a suture, which once distinctly marked a separate nucleus or germ of bone. The trace of the suture extends sometimes from the summit of the ascending process of the maxillary bone to the inferior margin of the orbit, and I have not only seen this trace and suture frequently, but, if I recollect aright, I have seen the laminæ forming a distinct bone in persons at twelve or fifteen years of age, and even later. There can be no doubt then of this being a separate germ or nucleus in the young head, and entitled to a name; *external lachrymal bone: os lachrymale externum.* At this period (soon after birth) six alveoli may be observed, within which are lodged the incisor, canine, and deciduous molar teeth, which have not yet appeared. The *juga alveolaria* (projection formed on the outer side of the external alveolar border or wall) are very large and thin; the maxillary series is small, and perhaps no part has as yet that shape it will afterwards acquire in the adult; but of all parts of the bone, it is the dental portion which, as well in the lower as in the upper jaw bones, undergoes the greatest change; and to it, therefore, and to what it contains, the following remarks will be chiefly directed.

Of all the characteristic features of race, there is none, perhaps, more constant than the difference observable in the comparative size of the jaws, and especially of the upper jaw, of which the superior maxillary bones form by far the larger portion. The great size of these bones in the coloured races as compared with their white brethren is quite remarkable; nor does it signify where the dark race may be placed, whether near the poles and within the arctic circle, or under the equator. Wherever found, the coloured man shows all his peculiarities. The jaws of the Esquimaux, the Tartar, the Australian, and the Red Indian, are quite as large as in any Negro.

The maxillary tuberosity is a part of the bone undergoing great changes, connected, however, with the development of the wisdom-tooth. When the nasal bones are naturally narrow, as they are in some individuals, and apparently in some races of men, the ascending process of the maxillary bone compensates for such deficiency by an increased breadth. The canine fossa is occasionally of extraordinary depth, but this is more an individual variety than one of race. In respect to the alveolar border, or process, the outer lamina is thinner, than the inner; the alveoli vary in different persons, since in some all the teeth do not appear. The vitality of the alveolar edge differs from that exhibited by the rest of the bone; the process, in fact, at many points ceases to be deposited; it disappears, and having no longer any support, the teeth fall out prematurely. This, of course, is the reverse of what happens when the teeth are forcibly driven or pulled out; in this case the alveolus disappears, as being no longer required. The vitality then of the dental portion of both jaws must differ from the vitality of common bone; the tissue is more spongy, is looser, and obeys other laws. In many animals the teeth grow to it, and form one with it, as in some fishes and serpents; in others, and occasionally even in man, the alveolar cavity may enclose the tooth completely in a case of bone, where it will remain, causing no disturbance during the life of the animal.

One of the most remarkable circumstances in the history of the superior maxillary bones is the history of the fissure or line, seen occasionally on the surface of the palatal process of the maxillary bones I now speak of. This suture or fissure when present, occupies the position of what we should expect an inter-maxillary suture to occupy, such as we find in nearly all the mammals separating the inter-maxillary bones, as they are called, from the maxillary, and generally persistant through life. Those who have not seen the inter-maxillary bones in the cranium of one of the lower mammals, had better examine them in the sheep, the ox, or the horse, for it is quite useless, and worse than useless, to speak to any one of structures they have not seen. On looking at these bones in the sheep, ox, or horse, the student will observe, that they are placed between the maxillary bones (upper); that they form the margins of the anterior nostrils and a portion of the palate; that they not unfrequently run upwards a considerable way between the nasal bones and the ascending process of the maxillary bones, and that they carry in alveoli belonging to them, all the incisor teeth belonging to the upper jaw. A question naturally arises—are these bones peculiar to the lower animals? or do they also form a portion of the human skeleton? That they are not found as separate or distinct bones in any adult skull is true enough; I have never myself met with an adult skull of any race or nation showing separate or distinct inter-maxillary bones; still they exist as separate germs in the human fœtus, and I find it stated that Weber has succeeded by means of dilute sulphuric acid in separating them from the maxillary in the cranium of a child, somewhat more than a year old. To this question, Goethe and most transcendental anatomists have attached more importance than it really merits; the doctrine of the unity of the organisation does not require such proofs as they look for here. Nor is this question one of modern times; it was started by Vesalius, and since his era has been often debated. No philosophic anatomist, I should think, of modern times, doubts the existence of the inter-maxillary as distinct bones in the human fœtus. The palatal process varies much in different individuals, being rough or smooth, deep or shallow, concave, sometimes to a great extent; and I have once or twice seen it convex along the mesial line or maxillary suture. The configuration of the sinus varies infinitely, but I have never remarked it to be absent. Its uses are absolutely unknown. The student who would understand the anatomy and physiology of the second division of the fifth pair of nerves ought to study the descriptive anatomy of the superior maxillary bones with the utmost attention.

Palate Bones.—The descriptive anatomy of these bones is, no doubt, extremely difficult, but little can be said of their physiology. The same remark applies to the *malar bones*; they differ, no doubt, in the various races of men, being remarkably large in the dark races. In the Celt they are supposed to be high, prominent, and large, but this may be owing partly to the form of the soft parts covering the cheek. When these sink in, the malar bones, of course, appear prominent upon any face. In the skeleton of the face of the Bosjeman, for example, these bones are not particularly prominent nor large, and yet in the living adult face they appear remarkably so. The cheeks are hollow; there is no subcutaneous cushion of fat under the skin; the chin is pointed, and the angles of the jaw appear, so that, at a distance, the face of the Bosjeman resembles a skull, with merely a yellow dirty piece of parchment drawn tightly over it; nothing can be more hideous. Some anomalies of this bone have been described: its absence by Meckel, and its division into two or three separate portions by Sœmmering. I have seen no varieties myself.

Nasal Bones.—These bones, unlike the preceding, present a very great number of varieties, of which some perhaps amount to distinctions of race. Even in the white races they are not symmetrical; sometimes one bone scarcely reaches the frontal, or they unite together partly or throughout their whole length. But it is in the dark races, as has been already shewn in some of the preceding lectures, that important differences exist, in the Bosjeman, for example, and in others of the dark races. Extreme narrowness at the top, and total disappearance of the nasal suture, are common enough. This does not, however, diminish the capacity of the chambers of the nose. The probable existence of a third bony nucleus interposed between the *ossa nasi;* an inter-nasal bone, in fact, has been already alluded to. Its history would require to be investigated in the fœtus.

Os Unguis.—These bones are said to present many varieties, but they have not seemed to me important: sometimes absent, or very small, or without a crest, which I have not unfrequently observed. Although small and extremely delicate, a muscle of some size (the tensor tarsi) is attached to them.

Of the *vomer* little need be said; at birth it is deeply divided into two portions (plates), which run together about the twelfth year; one of these plates of bones may afterwards disappear. The vomer is seldom quite mesial, being convex towards one nostril, and concave towards the other, and I think it liable to incomplete development.

Turbinated Bone.—There are but two turbinated bones in man, and it is, therefore, singular why anatomists should still continue to call them the *lower* turbinated bones, as if there really were any others. The turbinated portions of the ethmoid are mere processes of that bone. As it is my intention to return to the physiology of these interesting bones, when speaking of the nasal cartilages and their muscles, I shall be as brief as possible here. They vary in size and form, being sometimes strongly, and sometimes less turbinated or rolled. It is to the anterior extremity of this bone that we find attached, *in the horse*, that singular spur-shaped cartilage and fibrous prolongation which plays so important a part in the physiology of the nostrils in that animal.

† A full account of these singular structures will appear in the *Veterinary Record* for July, edited by Professors Spooner and Morton.

THE STRUCTURE AND FUNCTIONS OF THE BRAIN, WITH NEW VIEWS ON THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine,

Formerly Physician to the Bicetre and Salpetriere Asylums: Author of the "Traite Medico-Philosophique sur l'Alienation mentale" "Medicine Clinique," "Nosographie Philosophique," &c., &c., Translated with Notes illustrative of some important doctrines in Physiology, Phrenology and Moral Education,

By Dr. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c.

(Continued from page 37.)

CASE II. M. D.—A military man aged 42 during the campaign of 1812, had an attack of mania in Germany, that lasted from 9 to 10 months. On recovery, he resumed his service, but his disposition which was before mild and very lively, became gloomy and susceptible. He felt irritated, at the slightest cause, and chagrined at the successes of our enemies. In 1814 he caught a gonorrhea for which he was unskilfully treated. Some time

after he felt passionately in love with a German lady whom he met at Paris; he asked her in marriage and was refused. His head already weakened, could not bear up against this blow, and a fresh attack of mania burst forth with such violence that it was necessary to remove him to an asylum. After seven or eight months he left apparently well, but he still suffered from head-ache, and was subject to be alarmed from the slightest cause.

Nearly fifteen years elapsed thus in retirement and inaction. In the month of October 1832, after a banquet, at which he drank and spoke a good deal and with unusual vehemence, he was seized with an attack of furor so violent that it took six men to master him. He was again sent to an asylum.

During a month the delirium and agitation were excessive; he continued furious till the middle of the second month, when he began to be a little more quiet, and it became possible to engage his attention by speaking to him of subjects, in which he felt an interest: now and then, he would acknowledge that he felt wrong in his head, but he would quickly fall back into the habitual extravagance of his ideas.

During the third month, he was observed to be a good deal more calm, and to pass entire hours in silence; he was immoveable and replied to the most pressing questions, slowly and with repugnance: the stupor soon became complete, and he appeared neither to see, hear, nor understand. If his arm were raised, it remained extended for several minutes, and fell only gradually and by jerks.

Visiting him on the 7th January, I perceived streaks of blood in his sputa. On exploring the chest I found both lungs hepatized at their base. This double pneumonia was the more latent from the patient not complaining of any pain, and from the breathing appearing almost natural, and lastly from the pulse being remarkably feeble and depressed. In spite of active treatment, he died on the 8th, in the evening.

AUTOPSY—EXTERIOR—CORPULENT—ATHLETIC CONSTITUTION.

Head.—The bones of the cranium were thick, injected, and hard to be sawed. The dura mater seemed as if insufflated and was strongly applied to the inside of the skull. The vessels on its external surface were gorged with dark blood towards the parietal prominences, the arachnoid was covered with an albuminous exudation arranged in a pretty thick layer; the rest of the membrane was healthy, transparent and uplifted by an accumulation of serum which flowed away as soon as the membrane was divided.

In the brain, the intervals between the convolutions were almost effaced in the frontal region; they seemed to be stuck to each other, giving to this part the appearance of a plain round surface; the grey substance was red, and deeply injected; its middle layer especially was of a violet red, and seemed ecchymosed. This alteration formed a striking contrast to the appearance of the same substance in the lateral and posterior regions of the brain, where it was entirely colourless, pale, confounded with the medullary substance in several places, and so covered and imbued with serum that it oozed out in good sized drops, when pressure was made on the sides of the incisions in the convolutions.

The white substance was of remarkable density, and in colour resembled brilliant white satin; the medullary fibres were traceable to the eye, and could be torn into long strips intercrossed at the top of the laceration; the ventricles small and collapsed, contained but little serum, the lining membrane perfectly healthy. The cerebellum, and spinal marrow normal.

Both lungs were entirely hepatized at their base; they were crepitant at their apex. All the other viscera healthy, except the bladder, the walls of which, thickened and rugous, were the seat of a chronic affection.

Reflexions.—This case, like the former, presents an inflammatory complication of a part of the brain, but it is more curious on account of the œdema of the brain, inasmuch as the double pneumonia having suddenly caused death, we are enabled the more easily to recognize in the brain the disposition and quantity of the fluid effused. Let us examine in succession the relation of these lesions to the symptoms.

1°. The morbid adhesion of the convolutions in the frontal region, shows an abnormal disposition, produced by the former attack, which disturbed his reason so many years before. This opinion is still further confirmed by the fact, that it was in the same region, already predisposed to it from the former attack, that in the last period of life an inflammatory congestion supervened, the symptoms of which could not be manifested externally, on account, in the first place, of the cerebral œdema, which abolished the sensibility, and in the next, of the powerful derivation produced by the double pneumonia.

2°. It was during the third month from the attack, that the patient, till then so agitated and furious, began to become silent and immoveable, soon to lapse into complete stupor. We must refer to this period the commencement of the cerebral œdema; according as the serum compresses the convolutions and penetrates into their substance, the symptoms of the annihilation of the intellectual and motile powers become more and more aggravated. We have here a remarkable symptom in the sort of catalepsy observed in the arms. Does true catalepsy depend on a still greater degree of compression made either on the brain, or on the parts arising from serous effusion? It may be so, if we observe attentively the symptoms of partial catalepsy that occur in some of the insane.

3°. The acute affection of both lungs, the commencement of which was not marked by any sign of pain, or by any symptom of fever, heat, cold, or acceleration of the pulse, furnishes a striking example of the obscure and latent character which the most acute affections assume amongst the insane. There can be no doubt in the case here related, that the suspension of the influence of the brain was the cause of the non-manifestation of the ordinary symptoms of pneumonia.

I have related these two cases first, because they shew in the brain complications more or less numerous with cerebral œdema. The cases that follow will shew this disease in its simplicity, and consequently will enable us to see its lesions and symptoms in a clearer light.

CASE III.—Jeanne L——, aged 33, of delicate and irritable constitution, was reduced to indigence by her husband's dissipation. She was brought to the Salpetriere in 1831, labouring under an attack of mania from grief. Five months after, her recovery was deemed sufficiently advanced to allow of her being sent home; but the same causes which before had disturbed her reason, penury, and the abandonment of her husband, soon produced a return of her malady. On the 7th of January, 1832, in a fit of insanity, she attempted to jump from the Pont Royal into the Seine. She was prevented, and next day she was sent to the Salpetriere by the police.

Her appearance bespoke distraction and fright; she replied only in monosyllables. When asked to explain the cause of her desperation, she said she did not know. During the first fortnight she appeared to be pretty tranquil, although still a prey to some feeling of profound grief. On the 21th she had an attack of furious mania, which lasted four days, during which she vociferated continually, and gave way to the most violent agitation.

In the beginning of February she began to get calm; her recollection became clearer and her intellect acquired remarkable lucidity; she was sent among the convalescents. In about a month her cure seemed perfect, when during the night she was attacked with hallucinations. She got up, cried, and complained of violent tightness round her head. This agitation lasted three weeks, and was followed by absolute silence. The ideas and memory became confused, she remained for hours in the same position, and all her movements were sluggish. On the 2nd of April the stupor was complete, and so great was the insensibility of the skin, that she was not conscious of the application of two moxas to the nape of the neck. At the same time, there was slow continued fever, accompanied with abundant fetid expectoration, and colliquative diarrhea terminated her existence on the 28th May.

Autopsy.—The limbs and body were much emaciated, the ancles œdematous.

The cranium thin, and white, was remarkably developed in the supra occipital region. The dura mater was uplifted by a considerable accumulation of clear serum which ran out as soon as the membrane was cut into. The arachnoid healthy and transparent. The pia mater on the other hand throughout its whole extent engorged and reddish, presented in several places thick solid patches; and in others it appeared to be covered with solid granulations; it further contained a turbid serum.

The convolutions were deeply separated and filled with serum; the cortical substance destitute of colour and deeply imbued with serous fluid which exuded in large drops when pressed between the fingers. The white substance had a brilliant varnished appearance.

The collapsed ventricles contained but little serum; the other nervous centres presented nothing remarkable.

In the chest, the right lung was disorganized; in its upper part, there was a large cavity containing fœtid pus. The small intestines only presented some blackish ulcerations and a few red patches.

Reflexions.—This case exhibits a striking example of the abolition of intellect which we are now considering. The chief alteration is undoubtedly that of the pia mater; the thickening, granulations and redness of this membrane, plainly shew that it was at several different times, the focus of an acute congestion, which extending to the surface of the brain produced the several attacks of mania observed in the case.

After several alternations of cure and relapse, the pia mater became in the last month, the seat of a large serous exhalation, which being no longer sufficiently absorbed accumulated round the brain, penetrated into the grey substance which it deprived of colour, and by greatly uplifting the membranes, produced on the encephalon the effects of general compression shown in the stupor, and cutaneous insensibility.

It is possible the cerebral œdema might have been cured in time, had not the fatal complication of phthisis supervened to hasten death.

Case IV.—Anne a sempstress, aged 22, extremely sensitive, was delivered for the third time in 1826 of a well-formed infant. Having lost her two other children in attempting to bring them up herself, she determined on sending the infant to be nursed, although it was only with difficulty she was able to provide for her own wants. Her separation from the baby caused her the liveliest grief. On the sixth day after her delivery, she got up and walked bare-footed on the cold flags; she was instantly seized with a cold shiver, which forced her to take to her bed again. In the evening the lochia were entirely suppressed, the hands were œdematous, and the head ached violently. On the tenth day there was violent delirium, loquaciousness, and extreme restlessness. She was sent in this state to the Hotel-Dieu, whence she was transferred, two days after, to the Salpêtriere.

The confusion of her ideas was extreme; she started at the slightest noise, talked incessantly, and had hallucinations; she imagined herself surrounded by children, and sought for her own child amongst them. Pulse frequent, skin dry and burning. During six weeks she remained in this state, when a calm succeeded. A profound stupor seemed to benumb her intellect and power of motion; it was impossible to get a word from her, and her jaws were closed convulsively. She remained constantly in bed; her limbs were remarkably rigid: diarrhœa set in; several eschars formed on the back, sacrum, and heels, and she expired on the seventh of July, six months after her confinement, in the last stage of emaciation.

Autopsy—Skull thin and white; the dura mater adhering in several places to the calvarium. The arachnoid healthy, but uplifted by serum, particularly throughout the posterior region. In order to be certain that this injection of the posterior part was not the effect of the position of the body, which was laid on the back, I had it reversed, but still the fluid remained as before. It was then perceptible that throughout the whole anterior region, the arachnoid adhered intimately to the

substance of the brain, and the membrane there was opaque and thickened; the subjacent cortical substance was of a redder colour than that of the posterior part. Throughout the occipital region the convolutions were separated and their intervals filled with an abundant serum, which appears to have filtered even into the tissue of the brain itself; no blood-vessels could be discovered in them, and by pressing, small drops of serum were squeezed out.

The white substance throughout, appeared of the natural aspect and consistence; and this was the case with the annular protuberance and the cerebellum. Lungs healthy; the abdomen presented traces of chronic peritonitis; the peritoneum thickened, and covered in some places with membranous patches, some of which had peeled off, and were floating in a whitish puriform serum.

The stomach wrinkled, presented some red streaks; the small intestines reddened throughout, their mucous membrane thickened, sanguineous, and dotted with dark spots, resembling the depressed pustules of variola. The uterus healthy.

Reflexions.—In this case, the œdema of the brain put on a peculiar character, inasmuch as it was confined to the posterior part. Is it on account of the compression being thus circumscribed to the posterior lobes, that the particular symptoms of rigidity of the jaws and arms were observed? The fact itself is curious, and may furnish a point for comparison with similar cases.

The adhesion of the whole anterior region shews the traces of the morbid action, to which the loss of reason in the first instance is to be attributed; and this supposition is further confirmed by the albuminous patches found in this region.

ORIGINAL RESEARCHES ON THE FRONTAL SINUSES, WITH OBSERVATIONS ON THEIR BEARINGS ON THE DOGMAS OF PHRENOLOGY,

By Sir W. Hamilton, Bart., F.R.S.,
Secretary to the Senate of the University of Edinburgh.

Before proceeding to state in detail the various facts and fictions relative to the frontal sinus, (1) it will be proper to premise some necessary information touching the nature and relations of the sinuses themselves.

These *cruces phrenologorum* are two cavities, separated from each other by a perpendicular osseous partition, and formed between the tables of the frontal bone, in consequence of a divergence of these tables from their parallelism, as they descend to join the bones of the nose, and to build the orbits of the eye. They are not, however, mere inorganic vacuities, arising from the recession of the bony plates; they constitute a part of the olfactory apparatus; they are lined with a membrane, a continuation of the pituitary, and this, copiously supplied with blood, secretes a lubricating mucus which is discharged by an aperture into the nose.

Various theories have been proposed to explain the mode of their formation; but it is only the fact of their existence, frequency, and degree, with which we are at present interested. In the fœtus, manifested only in rudiment, they are gradually, but in different subjects variously developed, until the age of puberty; they appear to obtain their ultimate expansion towards the age of twenty-five. They are exclusively occasioned by the elevation of the external table, which determines, in fact, the rise of the nose at the period of adolescence, by affording to the nasal bones their formation and support.

Sundry hypotheses have likewise been advanced to explain their uses, but it will be enough for us, from the universality of their appearance, to refute the singular fancy of the phrenologists, that these cavities are abnormal varieties, the product of old age or disease.

But though the sinuses are rarely if ever absent, their size in every dimension varies to infinity. Laying aside all rarer enormities, and speaking, of course, only of subjects healthy and in the prime of life, in superficial extent the sinus sometimes reaches hardly above the root of the nose, sometimes it covers nearly the whole forehead, penetrates to the bottom of the orbit, and, turning the external angle of the eye-brow, is terminated only at the junction of the frontal and parietal bones. Now, a sinus is small, or almost null upon one side—on the other it is, perhaps, unusually large; while in no dimension are the two cavities, in general, strictly correspondent, even although the outer forehead present the most symmetrical appearance. In depth (or transverse distance between the tables) the sinus is equally inconstant, varying indeterminably in different heads, from a line or less to half an inch and more. Now, a sinus gradually disappears by a gradual convergence of its walls; now these walls, after running nearly parallel, suddenly unite. Now, the depth of the cavity decreases from centre to circumference; now, the plates approximate in the middle and recede farther from each other, immediately before they ultimately unite. In one cranium, a sinus, collected within itself, is fairly rounded off; in another, it runs into meandering bays, or is subdivided into separate chambers, these varying without end in their relative capacity and extent. In depth, as well as in extent, the capacity of the sinus is thus wholly indeterminable; and no one can predict from external observation, whether the cavity shall be a lodging scanty for a fly or roomy for a mouse.

It is an error of the grossest, that the extent of the sinus is indicated by a ridge, or crest, or blister, in the external bony plate. Such a protuberance has no certain or even probable relation to the extent, depth, or even existence, of any vacuity beneath. Over the largest cavities there is frequently no bony elevation; and women, in whose crania these protuberances are in general absent or very small, exhibit the sinuses as universally existent and not, perhaps, proportionably less extensive than those of men. The external ridge, however prominent, is often merely a sudden outward thickening of the bony wall, which sometimes has a small, sometimes no cavity at all, beneath. Apart also from the vacuity, though over the region of the sinus, no quarter of the cranium presents greater differences in thickness, whether in different subjects or in the same head, than the plates and diploe of the frontal bone: and I have found that the bony walls themselves presented an impediment which varied inappreciably from three to thirteen lines:—"*Fronti nulla fides.*"

But the "*fronti nulla fides,*" in a phrenological relation, is further illustrated by the accidents of its sinus, which all concur in manifesting the universality and possibly capacious size of that cavity. That cavity is sometimes occupied by stony concretions, and is the seat of ulcers, cancer, polypus, and sarcoma. When acutely inflamed, the sensibility of its membrane becomes painfully intense; and every one has experienced its irritation when simply affected with catarrh. The mucosity of this membrane, the great extent and security of the caverns, joined with their patent openings into the nose, render the sinuses a convenient harbour for the nidulation, hatching and nourishment of many parasitic animals; indeed, the motley multitude of its guests might almost tempt us to regard it as

———"The cistern for all creeping things
To knot and gender in."

"Chacun a son Verocquin dans la teste"—"Quemque suus vellicat Vermis"—are adages which from the vulgarity of the literal occurrence, would seem more than metaphorically true.(2) With a frequency sometimes epidemic,(3) flies and insects here ascend to spawn their eggs, and maggots (other than phrenological) are bred and fostered in these genial labyrinths. Worms, in every loathsome diversity of slime and hair—reptiles armed with fangs—crawlers of a hundred feet—ejected by the score, and varying from an inch to half an ell in length, cause by their suction, burrowing and erosion, excruciating headache, convulsions, delirium, and phrensy. With many a nameless or nondescript visitor, the leech, the lumbricus, the ascaris, the ascaris lumbricoides, the fasciola, the eruca, the oniscus, the gordius, the forficula, the scolopendra, the scorpiodes, and even the scorpion,(4) are by a hundred observers recorded as finding in these "antres vast"—these "spelunci ferarum"—a birthplace or an asylum.(5) And the fact, sufficiently striking in itself, is not without significance in relation to the present inquiry, that these intruders principally infest the sinuses of women, and more especially before the period of full puberty.

Such is the great and inappreciable variation of the frontal sinus and its walls, that we may well laugh at every attempt to estimate in that quarter, the development of any part of the subjacent hemispheres, were that part larger than the largest even of the pretended phrenological organs. But this is nothing. Behind these spa-

(1.) It is proper to observe, that the notes, of which the following is an abstract, were written above sixteen years ago, and have not since been added to, or even looked at. They were intended for part of a treatise to be entitled, "The Fictions of Phrenology and the Facts of Nature." My researches, however, particularly into the relations of the cerebellum, and the general growth of the brain, convinced me that the phrenological doctrine was wholly unworthy of a serious refutation; and should the detail of my observations on these points be ever published, it will not be done in a polemical form. My notes on the frontal sinuses having, however, been cast in relation to the phrenological hypothesis, I have not thought it necessary to take the labour of altering them,—especially as the phrenological fiction is, in truth, a complement of all possible errors on the subject of these cavities.

(2.) In the frontal sinuses worms and insects are *not unfrequently* found.—Voigtel Handb. d. Pathol. Anat. 1804, vol. i, p. 292. I quote him, *instar omnium*, as one of the best and one of the most recent authorities.

(3.) Forestus Obs. Med., Lib. xxi. schol. 28.

(4.) Hollerius de Morb. int. L. i, c. 1; Gesner Hist. Anat., L. v; Boneti Sepul. Obs., 121; Ferretti.—I here refer to the scorpion alone.

(5.) Long before the sinus was anatomically described by Carpi, this pathological fact had been well known to physicians. The prescription of the Delphic oracle to Demosthenes of Athens for his epilepsy shews that the Greeks were aware of the existence of worms in the frontal sinuses of the goat. (Alex. Trallian, L. i, c. 15.) Among the Arabians, Avicenna (Fenestella, L. iii, tr. 2, c. 3) tells us it was well known to the Indian physicians, that worms generated in the forehead immediately above the root of the nose, were frequently the cause of headaches; and Rhazes (Continet, L. i, c, 10) observes that this was the opinion of Schare and others. Among the moderns, my medical ignorance suggests more authorities than I can almost summon patience simply to name. The curious reader may consult, among others, Valescus de Taranta, Nicolaus de Nicolis, Vega, Marcellus Donatus, Trincavella, Benedetti, Hollerius, Duretus, Fabricius Hildanus, Zacuta Lusitanus, Hercules de Saxoni, Petrus Paulus Magnus, Angellinus, Alsarius, Cornelius Gemma, Gesner, Benevonius, Fernelius, Riolanus, Forestus, Bartholinus, Ferretti, Rolfinch, Olaus Wormius (who himself ejected a worm from the nose—was it a family affection?) Smetius (who also relates his own case,) Tulpius, Heurnius, Rousseus, Monardis, Schenk, Senertus, Montuus, Borelli, Bonetus, Hertodius, Kerkrigius, Joubert, Volkammer, Wohlfarth, Nannoni, Stalpert, Vander Well, Morgagni, Clericus, De Blegny, Salzman, Honold, Hill, Kilgour, Littré, Maloet, Saudifort, Henkel, Harder, Stocket, Slabber, Nil Rosen, Razoux, Schaarschmidt, Quelmatz Wolf, Blumenbach, Plouquet, Baur, Riedlin, Zacharides, Lange, Boettcher, Welgo, Wrisberg, Troia, Voigtel, Rudolphi, Bremser, &c., &c.; and of journals—Ephem. Misc.; Acta et Nova Acta Curios. Nat.; Commerc. Liter., Nov. 2; Breslauer Sammlung; Duncan's Med. Journ.; Edinb. Med. Essays; London Chronicle; Philadelphia Transactions; Blumenbach's Med. Bibl., &c., &c.

I may here mention, that the nidulation of the œstrus ovinus (which occasionally infects the human sinus) forms a frequent epidemic among sheep and goats. The horse, the dog (and probably most other animals) are similarly afflicted.

cious caverns, in utter ignorance of the extent, frequency, and even existence of this impediment; the phrenologists have placed, not one large, but seventeen of their very smallest organs; and have thus enabled an always insurmountable obstacle to operate in disproof of their system in its highest intensity.'

By concentrating all their organs of the smallest size within the limits of the sinus, they have, in the *first place*, carried all those organs whose range of development was *least*, behind the obstacle whose range of development was *greatest*. Where the cranium is thinner and comparatively more equal in thickness, they have placed all the organs (those of the propensities and sentiments) which present the broadest surface, and, as they themselves assure us, varying in their development from the centre to circumference by an inch and upwards; while all the organs (those of the intellect) which have the narrowest expansion, and whose varying range of development from the centre is stated to be only a quarter of an inch (less even than a fourth of the variation of the others);(6)—these they have accumulated behind an impediment whose ordinary differences are far more than sufficient to explain every graduation of the pretended development of the pretended organs from their smallest to their largest size.

In the *second place*, they have thus at once thrown one half of their whole organology beyond the verge of possible discovery and possible proof.

In the *third place*, by thus evincing that their observations on that one half had been only illusive fancies, they have afforded a criterion of the credit to be fairly accorded to their observations in relation to the other; they have shown in this, as in other parts of their doctrine, that *manifestation* and *development* are quantities which, be they what they may, can on their doctrine always be brought to an equation.

Nay, in the *fourth place*, as if determined to transcend themselves—to find "a lower deep beneath the lowest deep," they have even placed the *least of their least* organs at the very point where this, the *greatest obstacle*, was in its *highest potency*, by placing the organs of configuration, size, weight, and resistance, &c., towards the internal angle of the eye-brow, the situation where the sinus is almost uniformly deepest.(7)

Nor, in the *fifth place*, were they less unfortunate in the location of the rest of their minutest organs. These they arranged in a series along the upper edge of the orbit, where, independently even of the sinus, the bone varies more in thickness, from one individual and from one nation to another, than in any other part of the skull; and where these organs, hardly larger, are packed together more closely than peas in a pod. These pretended organs, if they even severally protruded from the brain, as they never do—if no sinus intervened—and if, instead of lying under the thickest, they were situated under the thinnest bone of the cranium; these petty organs could not, even in these circumstances, reveal their development by determining any elevation, far less any sudden elevation, of the incumbent bone. That bone they could only *attenuate* at the point of contact, by causing an indentation on its inner surface. This is shown by what are called the glands of Pacchioni, though erroneously. These bodies, which are often found as large as, or larger than, the organs in question, and which arise on the coronal surface of the encephalon, attenuate to the thinnest, but never elevate in the slightest the external bony plate; though there the action of the muscles presents a smaller impediment to a partial elevation than in the superciliary region. This I have frequently taken note of.

As it is, these minute organs are expected to betray their distinct and relative developments, through the obstacle of two thick bony walls, and a large intervening chamber; the varying difference of the impediment being often considerably greater than the whole diameter even of the organs themselves. The fact, however, is that these organs are commonly, if not always, developed only in the bone, and may be cut out of the cranium, even in an impuberal skull destitute of the sinus, without trenching on the confines of the brain itself. At the external angle of the eyebrow at the organ of slumber, the bone, exclusive of any sinus, is sometimes found to exceed an inch in thickness.

How then have the phrenologists attempted to obviate the objection of the sinus?

The first organs which Gall excogitated, he placed in the region of the sinus; and it is manifest he was then in happy unacquaintance with everything connected with that obnoxious cavity. In ignorance, however, Gall was totally eclipsed by Spurzheim; who, while he seems even for a time unaware of its existence as a normal occurrence, has multiplied the number and diminished the size of the organs which the sinus regularly covers. By both the founders, their organology was published before they had discovered the formidable nature of the impediment, and then it was too late to retract. They have attempted, indeed, to elude the objection; but the manner in which they have floundered on from blunder to blunder—blunders not more inconsistent with each other, than contrary to the fact; shows that they have never dared to open their eyes on the reality, or never dared to acknowledge their conviction of its effect. The series of fictions in relation to the frontal sinus, is, out of phrenology, in truth, unparalleled in the history of science. These fictions are substituted for facts the simplest and most palpable in nature; they are substituted for facts contradicted by none, and proclaimed by every anatomical authority; and they are substituted for facts which, as determining the competency of phrenological proof, ought not to have been rejected without a critical refutation by the founders of that theory themselves. But while it seemed possible for the phrenologists to find only truth, they have yet continued to find nothing but error—error always at the greatest possible distance from the truth. But if they were thus so curiously wrong in matters so easy, notorious, and fundamental, how far may we not presume them to have gone astray where they were not, as it were, preserved from wandering.

The fictions by which phrenologists would obviate the objection of the frontal sinus, may, with the opposing facts, be divided into four classes;—as they relate 1st, to its *nature* and *effect*; 2nd, to its *indication*; 3rd, to its *frequency*; and 4th, to its *size*.

I.—NATURE AND EFFECT OF THE SINUS.

Fact.—The frontal sinus only exists in consequence of the recession of the two cranial tables from their parallelism; and as this recession is inappreciable, consequently, no indication is afforded by the external plate of the eminence or depression of the brain, in contact with the internal.

To this fact, Gall opposed the following:

Fiction.—The frontal sinus interposes no impediment to the observation of cerebral development; for as the walls of this cavity are exactly parallel, the effect of the brain upon the inner table must consequently be expressed by the outer.

Authorities for the Fiction.—This fiction was originally advanced by Gall, in his lectures, and, though never formerly retracted, has not been repeated by him or Spurzheim in their works subsequently published. I therefore adduce it, not as an opinion now actually held by the phrenologists, but as a part only of that cycle of vacillation and absurdity which, in their attempts to elude the objection of the sinus, they have fruitlessly accomplished. That it was so originally advanced, is shown by the following authorities; which, as beyond the reach of readers in general, I shall not merely refer to, but translate.

The first is *Frorlep*; and I quote from the 3rd edition of his "Darstellung," &c. which appeared in 1802. This author was a pupil and friend of Gall, on whose doctrine he delivered lectures, and his work is referred to by Gall, in his Apologetic Memorial to the Austrian Government, in that very year, as containing an authentic exposition of his opinions.—"Although at this place, the frontal sinuses are found, and here constitute the vaulting of the forehead, nevertheless, Gall maintains that the brain, in consequence of the walls of the sinuses lying quite parallel (?!), is able to affect likewise, the outer plate, and to determine its protuberance."—p. 61. The doubt and wonder are by the disciple himself.

The second authority is *Bartels*, whose "Anthropologische Bemerkungen" appeared in 1806. "In regard to the important objection drawn from the frontal sinuses, Gall's oral reply is very conformable to nature. 'Here, notwithstanding the intervening cavity in the bones, there is found a parallelism between the external and internal plates of the cranium.'"—p. 125.

Proof of the Fact.—In refutation of a fiction so ridiculous, it is unnecessary to say a single word; even the phrenologists now define the sinus by "a divergence from parallelism between the two tables of the bone."(7.)

It was only in abandoning this one fiction, and from the conviction that the sinus, when it existed, did present an insuperable obstacle to observation, that the phrenologists were obliged to resort to a plurality of fictions of far inferior efficacy; for what mattered it to them, whether these cavities were *indiscoverable*, *frequent*, and *capacious*, if, in effect, they interposed no obstacle to an observation of the brain.

(To be continued.)

(6.) Combe's System, &c., p. 31. "The difference in development between a large and a small organ of the propensities and some of the sentiments, amounts to an inch and upwards; and to a quarter of an inch in the organs of intellect, which are naturally smaller than the others.

(7.) Every one who has ever examined the sinus knows that what Schulze has observed is true—in illo angulo qui ad nares est, cavitates fundus est et hoc in loco fero ossium laminæ a *se invicem maxime distant*.—(De Cav. Cranii Acta Phys. Med. Acad. Caes, I, p. 508.)

(7.) Combe, System, p. 32.

PROGRESS OF FRENCH SCIENCE.

FROM OUR OWN CORRESPONDENT.

Paris, May 15, 1845.

On Diseases of the Eye. By Professor Velpeau.—According to the promise made last year, the eminent surgeon of la Charité has resumed his lectures on these diseases, commencing with inflammation of the iris.

Iritis.—This affection was but little studied by ancient writers, but in compensation as it were, modern authors have, within the last twenty years, paid particular attention to it. The silence of the former, and the researches of the latter have caused several errors which it is necessary to point out. It was supposed, that, as iritis was not described in ancient, and occupied so considerable a portion of modern works, it was not so frequent formerly as at the present day. This is easily explained by reflecting on the manner in which the diseases of the eye were divided by the older writers: all were comprised under the denomination of internal and external ophthalmia; inflammation of the different internal parts of the eye itself constituted the former, whilst that of its appendages formed the latter. It is, therefore, not surprising that iritis should not have been studied apart, since it was included under the generic term, internal ophthalmia; yet it is certain that it was known, for Maitre Jean, Janin, and St. Yves mention it, and Demours in his work quotes several cases but it must, however, be confessed, that until of late this affection was but little attended to. Formerly, practitioners admitted but two species of ophthalmia, to which they added an epithet according to the constitution of the subject; a mode of classification, which, even at the present time, some persons are disposed to adopt. In the commencement of the present era, iritis was the subject of several memoirs; Smith and Dr. Gimelle studied it; but it was only in 1823, that M. Gillet de Grandmont sustained publicly his thesis on this affection. Previously to this period it was known in Germany and England; Travers, Saunders, and some others, having already made it the subject of their studies. It would, however, be difficult to prove that iritis was more frequent formerly than at the present time, and it may be added, that

there is no reason to believe that such was the case. There are, sometimes, facts by which we may explain the greater frequency of certain diseases at one period than at another; in the present instance none exist: all that can be asserted is, that iritis is one of the diseases of the eye, which is frequently, very frequently observed, and comes immediately after inflammation of the tarsi, of the conjunctiva, and the cornea. This would be sufficient to prove how important it is that the practitioner should be familiar with the various forms of this disease, but a still more powerful motive exists, viz.: the attendant danger, which makes it absolutely necessary to study this phlegmasia more attentively than those already described, for when it terminates favourably, it leaves indelible marks, accompanied by more or less important derangement in the functions of the organ. Iritis is, therefore, an affection which is deserving of the surgeon's most serious attention.

Divisions.—Iritis may be divided into acute, chronic, simple, specific, or presenting various complications, according to the peculiar constitution of the patient or the place in which he resides. The German authors have established numberless divisions, but they are superfluous, if not injurious; thus, they admit thirty varieties of iritis, distinguished by the terms anterior, posterior, rheumatic, gouty, abdominal, syphilitic, &c. My opinions on this subject, which have been openly expressed, have often drawn from my opponents epithets far from flattering. Their mode of studying diseases is perhaps, not very scientific, since it is the custom in that country to separate the various branches of medicine, and to create a professorship for each specialty, so that persons, otherwise distinguished for their talents, are confined to a very narrow circle, beyond which they perceive nothing, and are led to consider trifles as things highly important. This is a misfortune for science. Thus Baer, whose talent is well known, recognises fifty or sixty different species of cataract. Two things should be avoided; huddling together all the various inflammations of the eye, on the one hand; and creating superfluous and numberless divisions on the other. The prudent practitioner will always keep a medium.

Definition.—Iritis may be defined to be a distinct inflammation, which cannot be confounded with other affections of the eye without great danger. This is evident, since it may exist alone; but it must not be supposed that, therefore, iritis is always unattended by inflammation in the surrounding tissues, but merely that the phlegmasia commences in the iris, and constitutes the principal affection, whilst that of the neighbouring parts is sympathetic. Again, strictly speaking, a distinct inflammation does not exist in any organ; for instance, no one denies that peritonitis is a phlegmasia of the serous membrane of the abdomen, and that the inflammation may extend to the neighbouring cellular, muscular, and mucous tissues, still it is generally admitted, that the former is the principal disease, and like all affections of a distinct nature, has its peculiar causes, symptoms, mode of development, and termination. Now, is not all this observed in iritis?

Varieties.—It may be admitted that the inflammation may commence on the anterior or posterior surface of the iris, or in its parenchyma. Scientifically speaking, this is correct, but it is not less true, that in a very short time the whole organ becomes affected. The phlegmasia may also be partial, general, or more or less modified by the constitution of the patient; but, in admitting that, owing to these several circumstances, there may be modifications of the disease; we are far from stating that each of these constitutes a special inflammation? One variety may be said to have a specific origin, viz., the syphilitic: but as to the scrofulous, rheumatic, arthritic, or such like, they ought to be rejected, as their symptoms may be observed in simple iritis. Moreover, how is it possible to admit the influence of a rheumatic, gouty, or scrofulous virus, on the constituent parts of the eye, and on the iris in particular, when many distinguished physicians consider the existence of a virus peculiar to each of these diseases chimerical? Do not many eminent practitioners state that rheumatism is a phlegmasia of the fibrous and synovial tissues? Again, in admitting that gouty iritis exists, its characteristic symptoms are often observed in patients admitted into hospitals, while it is well known that gout is a disease very seldom seen there. The same remarks are applicable to scrofula, and though the diseases of the eyes are, doubtlessly, modified by this form of constitution, still they do not in this respect form an exception, as all other affections are equally so. As to the opinion that scrofula is a disease of a peculiar nature, and that the diseases of the eyes, on account of the modifications produced by it, are separate maladies, it is inadmissible. As a constitutional affection scrofula certainly exists; but as one of a peculiar nature, it cannot be admitted: at the same time, let it be well understood, there is no doubt that phlegmasiæ of the eyes, and especially iritis, may present a particular character under the influence of a rheumatic, scrofulous, or any other diathesis, in this respect resembling all the diseases with which individuals of these constitutions may be affected. Thus, if a rheumatic person is affected with pleuritis, pneumonia, or any other malady, does it not present some peculiarities? Will it not be the same with a scrofulous individual? Now, if iritis occur in these cases, it will likewise offer symptoms *sui generis*. The difference, however, is great between this mode of considering the influence of the constitution on the diseases of the eye, and principally on iritis, and the theory of the Germans, who assert, that it is possible to recognise a gouty constitution on inspecting the eye, an opinion completely erroneous, since the pathognomonic symptoms may be observed in persons who have never had an attack of gout in their lives. These are the principal differences between the French and German doctrines, but it may be stated that even in Germany this doctrine is nearly obsolete, and that the practitioners who profess it are ignorant of the progress of science, not only in foreign countries, but also in their own. Iritis may be modified by the constitution of the patient, but no variety of a specific nature exists, except the syphilitic, because no one can deny that a virus is the cause of syphilis, whereas this is not generally admitted in other affections.

Symptoms.—Those of acute uncomplicated iritis may be divided into three stages; in the first stage, more or less pain in the forehead, temple, and bottom of the orbit; photophobia; lachrymation; vision more or less impaired; very slight redness; cornea transparent; conjunctiva almost white; the sclerotica, on the contrary, presents a reddish pink tint, disposed in a circular form, somewhat analogous to the ring already described in keratitis, but differing inasmuch as it does not reach the cornea, which is surrounded by a small greyish-brown circle; this symptom is very important in the diagnosis of iritis, and is produced by the anatomical disposition of the cornea and sclerotica, it being impossible, from the mode in which these two membranes are united, for the vessels to reach their point of junction, and it is the space comprised between the cornea and iris which forms the circle. Though a phenomenon purely anatomical, it has been erroneously considered by the Germans as the sign of gouty iritis, and called, consequently, the arthritic circle; the natural colour of the iris more or less changed; this symptom is difficult to discover when both eyes are affected, as no comparison can be made, except when the colour of the iris was previously known to the medical attendant; mobility of the pupil more or less diminished; when one eye alone is affected, it is generally smaller than on the healthy side; its form may vary considerably; it may be irregular, angular, or in the shape of an oval triangle; the edges may have a velvety, flaky appearance; the pupil may be cloudy, caused by the diminution of the transparency of the humours. The characteristic signs of this disease are, sub-orbitar pain, slight photophobia and epiphora, injection, sight more or less impaired, red tint of the sclerotica, disposed in a radiated circle, small greyish-brown ring surrounding the cornea, a change in the normal colour of the iris, and modification in the shape and aspect of the pupil.

Intermittent Affection of the Bladder.—The Count de C——, after having been occupied some time superintending some workmen employed in draining a marsh, was seized with the following symptoms:—uneasiness, shiverings, followed by fever and violent pain in the bladder. Boyer, who was called in, diagnosticated cystitis, the more readily as he had previously been obliged to sound the patient several times, on account of a stricture of the urethra. Forty leeches were ordered to be applied to the hypogastrium. During the night the pain ceased on a sudden, but returned the next day with equal intensity, when Boyer ordered forty more leeches to be put on. Baron Michel, the Count's physician, who was afterwards sent for, recognised at once a case of febris perniciosa cystica, analogous to those he had frequently seen at Rome, and prescribed sulphas quinæ; unfortunately the remedy came too late; the severity of the two attacks, and the loss of blood, had so reduced the patient, who was very old, that the disorder proved fatal. At the *post-mortem* examination the bladder was found quite healthy.—*Gazette des Hopitaux.*

Dislocation of the Knee forwards, caused by forced extension of the Leg. By F. Jacquot, M.D.—Bauzon, sergeant in the 66th regiment of the line, ætat. 21; strong and muscular; sanguineous constitution; entered the military hospital at Metz half an hour after having met with the following accident:—Amusing himself with jumping on level ground, he fell, contrary to the rules of gymnastics, on the left foot, the leg being at the same time stretched to the utmost, and thrown slightly backwards, the right limb, which was carried forwards, not reaching the earth as soon as its fellow. Bauzon felt a smart pain in the knee, and fell immediately on his face. On examination, the state of the part was found to be:—the lower limb was flexed at an angle with the thigh, so that the articular surface of the tibia was in contact with the inner surface of the patella, the anterior sub-cutaneous face of which was directed upwards and forwards; the condyles of the femur were easily felt in the popliteal region, which was very tense; pulsations of the popliteal artery not so easily felt as generally stated, owing to its being contained in the inter-condylean furrow; triceps cruralis prominent; tendons of the crural muscles inserted on the tibia and fibula were stretched, and formed two slightly curved cords, the concavity looking upwards; limb mobile; flexion easily performed, and almost without pain, foot turned inwards or outwards, according to the position in which the limb was placed, the shortening not more than an inch; slight swelling on each side of the knee; very little pain; no ecchymosis; in all probability the only lesions were rupture of the crucial ligament, and some fibres of the gastrocnemii; all the tendons were uninjured. Reduction was easily effected by performing gentle and gradual extension on the leg, and without causing much pain. The only symptoms afterwards noticed were swelling of the knee, which soon disappeared, and pain in the sole of the foot, especially at its inner edge, and in the tendo Achillis, produced by the apparatus. Six weeks after the accident, the patient could move about without limping, except when fatigued; the knee was still weak, but not swollen. The patient was bled the day of the accident, and, after reduction, to subdue, or rather prevent the occurrence of inflammation; the apparatus was kept moist, first with Goulard water, and afterwards with camphorated spirits of wine. According to the author, this luxation was produced in the following manner:—When the body is thrown forwards, so as to cause the femur to form a right angle with the tibia, the inferior extremity of the anterior surface of the former presses on the upper edge of the patella, and as this bone reaches the anterior tuberosity of the tibia, it becomes firmly fixed. A lever of the first kind is thus obtained, the power being applied to the upper end of the femur; the fixed point being the patella, and the resistance being formed by the posterior ligament. When the power is sufficient to overcome the resistance, the condyles escape backwards in the ham, but not downwards, as shewn in the case just related. The editors of the *Archives* in recording this case, justly remark, that M. Velpeau, in stating that the leg might be bent so as to form a right angle with the thigh, without luxation taking place, spoke of extension alone; whereas, in Dr. Jacquot's case, two causes existed—

first, forced extension; and secondly, the sudden shock produced by the falling of the body on the ground, and that, by the union of these two causes, the luxation might easily be explained without having recourse to hypothesis.—*Archives de Medecine.*

* *Necrology.*—After a long and painful illness, Professor Breschet departed this life on the tenth of May, 1845, in the 53d year of his age. Gilbert Breschet was born at Clermont, Ferrand, in 1783, and received the rudiments of his education at the college in that town; after which, having made choice of the medical profession, he came to Paris to pursue his studies. In 1808 he was named *eleve externe* at La Charité, and in 1809 was appointed *interne* to the Hopital St. Antoine; in 1812 he received the degree of M.D., and on this occasion, in his thesis on acute dropsy, he showed that the disease was not always owing to an asthenic cause, but sometimes due to an augmentation of the vital properties of the serous membrane, and that in these cases antiphlogistic remedies were indicated; in 1818 he was nominated physician to the Bureau Central; in 1819, *chef des travaux anatomiques* at the Faculty of Medicine; the preparations made on this occasion are still to be seen in the museum of the Faculty; in 1820, the surgical wards of the Foundling Hospital were confided to his care, and in the same year, on the organization of the Academy of Medicine, he was included by his Majesty among its members (section of pathological anatomy); in 1822, he was appointed surgeon to the Hotel Dieu; in 1830, consulting surgeon to his Majesty Louis Philippe; in 1835, he was elected, by 47 suffrages, member of the Academyof Sciences, in the section of medicine and surgery, a place vacant by the death of Dupuytren; and finally, on the 22d July, 1836, he was named by *concours*, professor of anatomy at the University of Paris. His death will probably raise many a hope, and cause, perhaps, many a disappointment among the candidates for the places he has left vacant. Breschet published several important works, alone or in conjunction with others. Alone: Memoire sur l'Ectopie de l'Appareil de la Circulation, et particulierement sur celle du Cœur, 1826. Repertoire General d'Anatomie, et de Physiologie Pathologique, et de Clinique Chirurgicale, 1826. Recherches Anatomiques, Physiologiques, et Pathologiques sur le Systeme Veineux, 1829. Recherches Anatomiques et Physiologiques sur l'Organe de l'ouie et sur l'Audition, dans l'Homme and les Animaux Vertebres, 1836. Etudes Anatomiques, Physiologiques, et Pathologiques de l'Œuf dans l'Espece Humaine, et dans quelques unes des Principales Familles des Animaux Vertebres, 1833. Memoires Chirurgicales sur les Differentes Especes d'Aneurismes, 1834. Recherches Anatomiques et Physiologiques sur l'Organe de l'Audition chez lesOiseaux, 1836. Recherches Anatomiques et Physiologiques sur l'Organe de l'Ouie des Poissons, 1838. Histoire Anatomique et Physiologique d'un Organe de Nature Vasculaire decouvert dans les Cetacés, 1836. Le Systeme Lymphatique, Considerè sous les Rapports Anatomique, Physiologique, et Pathologique, 1836. Memoire sur une Nouvelle Espece de Grossesse Extra-Uterine, 1826. Recherches et Observations sur l'Aneurisme faux Consecutif du Cœur et sur l'Aneurisme desArteres, 1827. Memoire sur un vice de Conformation Congenital des Enveloppes du Cœur, 1826. Memoire sur une Nouvelle Methode de Traiter et de Guerir le Circocele et le Varicocele, 1834. Du Perione ou Membrane Caduque, de l'Hydro-Perione ou liquide contenu dans cette membrane; de la Nutrition du Fœtus pendant les premiéres périodes de la Gestation, 1832. Recherches Anatomico-Physiologiques et Chimiques sur la Matiére Colorante du Placenta de quelques Animaux, 1829. De la Dessication et des Meilleurs Moyens de Conservation des Pieces Anatomiques, 1819. Translation of Hodgson's Treatise on the Diseases of the Arteries and Veins, with Notes, 1819; and of a work of Gluge's,—Quelques Recherches sur la Structure des Membranes de l'Œuf des Mammiferes, 1837. With Dr. Jourdan, translation of Meckel's Anatomy, with Notes; and with Dr. Raspail, Anatomie Microscopique des Flocons du Chorion de l'Œuf Humain, 1828. Most of these works are accompanied by plates. Finally, several articles in the Dictionnaire de Medecine—the second edition now under publication—and numerous reports made to the Academies of Science and Medicine.

Academy of Sciences. Sitting of the 12th May. M. E. de Beaumont in the chair.

On the Quantity of Opium contained in the Papaver Somniferum Album. By M. Bonnafond, of Turin, corresponding member of the academy. The author obtained from 100 capsules of the papaver album cultivated in the garden of the Royal Academy of Agriculture, Turin, incised while still on the stem, fifty grains of opium, which furnished three grains and a half of morphia, or seven parts of pure morphia in one hundred parts of opium. The author likewise states, that transverse incisions of the capsules yield twice as much opium as the longitudinal, and that the product obtained has a very bitter taste, but does not exhale the virous smell of exotic opium.

On the Proportions of Azote contained in Organic Substances. By M. Melsens. The experiments performed by the author were, 1st, on sawdust—1.063 grains were mixed with the oxyde obtained by decomposing the nitrate of copper, and gave 1.01 azote—0.627 grains with finely pulverized oxyde of copper, obtained by calcination of the metal, gave 0.28 azote—1.260 grains with the same oxyde gave 0.94—1.024 grains with the same oxyde previously heated gave 0.53 azote. These results, however, must be considered as approximative only. 2nd. On albuminoid substances. The average quantity was 17.7 per cent.; M. Scherer found 15.8 per cent; M. Mulder 15.7 per cent; Professor Dumas and M. Cahours 16.6 per cent. 3d. On the portion of fibrine insoluble in boiling water; according to M. Mulder it contains 14.8 per cent. of azote; to M. Dumas and Cahours, 16.0 per cent.; and to the author, 19.5 per cent.

On the Changes of the Magnetic Poles. By M. Choron, of Troyes. The author long since remarked that it was sufficient to bend an iron rod in order to change the magnetic poles; thus in soldering a plate of zinc, copper, or platina on one of the extremities of a common iron rod, and presenting it to a magnetic needle, he remarked that the attraction was changed into repulsion when the iron rod was bent; it may also be attractive or repulsive according as it is presented above or below the magnetic needle. This is not subjected to any positive law, nor is the soldering necessary to produce it.

On the Products of the Decomposition of Minerals of the Class of Silicates: by M. Ebelmen, *Ingenieur des Mines.* The substances examined by the author were: 1° The bisilicate of manganese from Algiers. Composition :—

Pure.

Silica	45·49
Protoxyde of Manganese	39·46
„ „ Iron	6·42
Lime	4·66
Magnesia	2·60
	98·63

Altered by Calcination.

Water		10·14
Oxygen		8·94
Protoxyde of Manganese		43·00
Peroxide of Iron		6·60
Lime		1·32
Insoluble Residuum	Gelatinous Silica	2·40
	Unchanged Bisilicate	27·20
		99·60

Formula (Mn Fe Ca Mg) S^2

2° Bisilicate of Manganese of St. Marcel :

Pure.

Silica	46·37
Protoxyde of Manganese	47·38
Lime	5·48
	99·23

Altered.

Oxygen		4·44
Protoxyde of Manganese		47·71
Lime		0·90
Water		1·10
Insoluble Residuum	Gelatinous Silica	8·00
	Unchanged Bisilicate	44·47
		100.62

Formula (Mn Ca) S^2

3° Bustamite of the silver mines of Tetata, Mexico :

Pure.

Silica	44·65
Protoxyde of Manganese	26.96
„ „ Iron	1·75
Lime	14·43
Magnesia	0·64
Carbonate of Lime	12·27
	100·70

Decomposed.

Protoxyde of Manganese	55·19
Oxygen	10·98
Water	10·68
Peroxyde of Iron	1·56
Carbonate of Lime	14·03
Silica and Quartz	8·53
	100·97

4° Basalt of Crouzet (Haute-Loire) :—

Pure.

Water	4·9
Silica and traces of Titanium	46·1
Alum	13·2
Lime	7·3
Magnesia	7·0
Protoxyde of Iron	16·6
Potass	1·8
Soda	2·7
	99·6

Decomposed.

Water and Organic Matter	16·9
Silica	36·1
Alum	30·5
Lime	8·9
Magnesia	0·6
Peroxyde of Iron	4·3
Potass	0·6
Soda	0·9
Oxyde of Titanium	0·6
	99·4

5° Basalt of Polignac (Haute-Loire) :—

Pure.

Water	3·7
Silica	53·0
Alum	18·4
Lime	6·8
Magnesia	3·5
Protoxyde of Iron	9·5
Potass	2·7
Soda	3·1
	100·7

Decomposed.

Water and Organic Matter	3·5
Silica	58·1
Alum	22·6
Lime	2·9
Magnesia	2·2
Peroxyde of Iron	4.0
Potass	2·7
Soda	3·3
	99·3

6° Basalt of Kammer, Bael, near Eger (Bohemia).

	Pure.	Decomposed. 1st Stage	Decomposed. 2nd Stage.
Water	4·4	9·5	20·4

Protoxyde of Iron	12·1	8·3	0·0
Potass	0·8	0·5	0·2
Soda	2·7		
	100·5	100·0	98·3

The author concludes 1° that in the decomposition of the silicates containing lime, magnesia, protoxyde of iron, and manganese, and no alum; the silica, lime, and magnesia are eliminated, and tend to disappear altogether, and that in some the iron and manganese are either more highly oxydised, or seem to disappear; 2° that the decomposition of the silicates which contain alum and the alcalies, with or without the other bases, the alum is concentrated in the residuum of the decomposition, retaining a small portion of the silica, and a certain quantity of water; the other bases are eliminated with the greater part of the silica. The final product of the decomposition becomes more and more like the hydrated silicate of alum. The author likewise studied the causes of the decomposition.

On the Identity of the Chemical Properties of the Essences of the Artemisia Dranunculus, and the Pimpinella Anisum, by M. Ch. Gerhardt.—The experiments of the author prove, that the essence of the artemisia dranunculus is composed of an oxygenated substance, containing but very little carbon, and presenting the same composition, and the same mode of condensation as the essence of the pimpinella anisum. It boils at about 403° F., density at 552° F.=5·39—at 583° F.=5 28; formula—

Anisic Acid. Oxalic Acid.

$$C^{10} H^{12} O + O^{6} = C^{8} H^{8} O^{3} + C^{2} H^{2} O^{4};$$

remains liquid at 26° F. The author next examines the action of sulphuric acid and the chlorurets on these essences, and concludes—1° that the essence of the artemisia dranunculus is but a physical modification of the essence of the pimpinella anisum, or of the anethum fœniculum; its formula, like that of the two last, is $C^{10} H^{12} O$= 2 vol.; the chemical tests are the same. 2° That when these essences are mixed with sulphuric acid or certain chlorurets, on being isolated anew, they are changed into other isomeric compounds, one of which is liquid, and the two others solid. 3° That the liquid compound is to these essences, what *terebere* is to the essences of turpentine and lemon, the same composition, the same density, the same point of ebullition, the only difference being that it is somewhat more stable. 4° That the liquid compound, when sulphuric acid is added to it, produces the sulphonithates, unibasic salts represented by the formula $C^{10} H^{10}$ M S O^{4}.

Academy of Medicine; Sitting of the 13th May—M. Caventou in the chair.—The president informed the Academy of the death of Professor Breschet.

On the Influence of the Tobacco Plant on Workmen.—Dr. Ruefs, Physician to the Manufactory of Tobacco, Strasburgh, addressed a letter on this subject, in which he refuted several opinions contained in the report of Dr. Melier, relative to its influence on phthisis, intermittent fever, and rheumatism, as from statistical tables drawn out lately at Strasburgh, he finds, that these diseases are as frequent among the workmen of the manufactory, if not more so, than in the remainder of the population. Dr. Villeneuve mentioned that he had questioned several midwives, who frequently attend females employed in the tobacco manufactory, and that none had ever perceived that the amniotic liquid presented the odour of tobacco.—Professor Dubois: The fact quoted by Dr. Melier is certified by Dr. Stoltz, and is worthy of belief.—Dr. Villeneuve enquired if Professor Dubois had ever witnessed a similar case.—Professor Dubois, in reply, said that he had never attended a female under such circumstances, but even if he were to do so several times without remarking it, still he would not, on that account, conclude that such could never be the case.

Dr. Rochoux read a report on a memoir on hemiplegia, caused by lesion of nerves. Conclusion—that the memoir be sent to the Committee of Publication.

Dr. Pariset, who entered at the close of Dr. Rochoux's report, was requested to read the speech he made at the funeral of Professor Breschet, in the name of the Academy of Medicine. This discourse was listened to in dead silence, and received with unanimous and deserved applause.

On the Mineral Waters of Bagneres du Luchon.—Dr. Fontan, inspector of these waters, and corresponding member of the Academy, read a long and elaborate memoir on this subject, in which, after mentioning their chemical composition, their physical and therapeutic properties, he alludes to the diseases that may be benefitted by their use—enumerates a certain number of cures obtained by their means, and finally compares them with the mineral waters of Eaux Bonnes, Cauterets, and Bareges, pointing out the diseases in which they ought to be preferred. Two important remarks made by the author ought not to pass unnoticed; first, the distinction that exists between sulphurous waters, rendered such by the nature of the soil, and those which become so accidentally, by the decomposition of organic matter, acting on the sulphate of lime contained in the soil; secondly, that the use of sulphurous waters is a preservative against salivation in persons subjected to a mercurial course.—Dr. Girardin wished to make some remarks on the species of infatuation which has reigned of late relative to mineral waters; prospectuses of all descriptions are published, proclaiming the beneficial effects to be obtained from their use, and very often, it appears, from the way in which they are worded, that such is the opinion of the Academy, so that we ought in future to be on our guard, when a report is demanded on any mineral water. These observations are, however, in no way applicable to Dr. Fontan, whose researches and whose character have long since been known and fully appreciated by the Academy. As to the memoir just read, he remarked, that the waters of Bagneres du Luchon are highly lauded; that in the generality of cases, they ought to be preferred to those of Cauterets, Bareges, or Eaux Bonnes, and that though many successful, still no unsuccessful cases are quoted. This he considered injudicious, that is to say, to take isolated facts in order to appreciate the utility of mineral waters, instead of studying for years the modifications caused in the economy by their use: in this respect he considered that the rules laid down by Bordeu were the only really useful ones, and that they ought therefore to be followed. Professor Velpeau made some observations on the distinction made by Dr. Fontan in mineral waters, a distinction which he thought worthy of attention. Dr. Nacquart observed that there are two effects obtained from mineral waters; first, a general modification, which explains why to a certain extent all have a beneficial result on the same diseases, and that, though their properties are very different. Secondly, a special action, rendering them efficacious in some affections, and useless in others. Professor Roux coincided in opinion with Dr. Nacquart as to the modification produced in the system by the use of mineral waters, and as to the waters of *Bagneres de Luchon*, he could vouch for their efficacy in some cases, since it was by their means he was cured of a very extraordinary rheumatic affection, which had resisted various remedies. He thought Dr. Fontan's communication worthy of serious attention, the more so as his learned researches on mineral waters in general, and especially on those of the Pyrenees, are well known and highly esteemed. M. Chevallier considered it very difficult correctly to establish the efficacy of mineral waters: patients go to an establishment; if relieved, they return to accomplish the cure if possible; on the contrary, if they reap no benefit they do not go back; the successful cases are thus well known, and the unsuccessful ones are always concealed. As to the prospectuses, they have rather been useful than otherwise, since the number of patients has of late doubled, and even trebled. Dr. Prus asked in what way the waters of *Eax Bonnes* cured phthisis, when at its first stage, and by what symptoms he recognized the affection? Dr. Rochoux did not think it possible to diagnosticate the presence of tubercles in the nascent state; there are now in Paris upwards of 20,000 individuals who have more than 50,000 tubercles in their lungs, without their health being in the least disturbed. Dr. Fontan shared the dislike professed by Dr. Girardin for quackery, and in reading the result of fifteen years' laborious researches, it was not his intention to laud the waters of which he is inspector, nor to rank them above all others; in his memoir he recommended in some cases *Eaux Bonnes* and *Cauterets* in preference to *Bagneres de Luchon*; thus, the first is spoken of as more efficacious in the first stage of phthisis. (Here the speaker, in reply to Dr. Prus, enumerated the various symptoms by which he recognized the disease in this stage.) He agreed with M. Velpeau regarding the distinction between natural and accidental mineral waters, as deserving the attention of chemists.

On Incomplete Anchylosis.—Dr. Kault, physician to the Civil and Military Hospital of St. Brieu, corresponding member of the Academy, presented an apparatus, by which permanent extension may be maintained in complete anchylosis of the elbow and knee joints. The apparatus, which is very simple and easily applied, is composed of a splint made of a thin iron plate; a lever of the first kind on the convexity of the splint; two screws at one end of the lever, by which it is made to act; and a bracelet at the opposite end. The splint is fixed by straps on the posterior surface of the arm, or the anterior surface of the thigh, according as the elbow or the knee is the seat of the affection; the lever is then made to form an angle with the splint, the part by which it is attached to it inferiorly being moveable, and the bracelet is attached to the wrist or instep; this done, by means of the screws the apparatus is gradually straightened. The power of the lever is the more considerable from the fact, that when it acts, the straps which fix the splint press upon the flexor muscles, and prevent their spasmodic and involuntary contraction, which is known to be the principal cause of incomplete anchylosis, and is the most difficult to overcome.

GARLAND DE BEAUMONT, D.M.P., B.L., & S., &c
Honorary Physician to the Spanish Embassy.

NOTICES TO CORRESPONDENTS.

T. T.—*Styrol is prepared by distilling liquid Storax with carbonate of soda. Our correspondent will shortly be able to obtain the fullest information on this subject, as Mr. Warrington, secretary to the Chemical Society, has obligingly informed us that the paper by Drs. Blyth and Hoffmann on Styrol is in the press, and will be published very soon.*

A Subscriber. (*Devonshire.*) *Gentlemen in medical practice before* 1815, *will be allowed to be registered as General Practitioners. A foreign diploma, procured by purchase, without examination, will be worthless as to registration.*

M. R. C. S.—*Existing rights are maintained. The question is answered elsewhere. None will register as General Practitioners* without *examination, except those in legal practice at the time of passing the Bill. Present Students will be provided for by the Council of Health.*

A Subscriber, Lynn.—*None will be able to register as physicians, and practice as General Practitioners (recovering fees), but those actually physicians at the time the Bill may pass. The St. Andrew's degree would be sufficient. The London College of Physicians forbid the practice of pharmacy to their members.*

The proper and best course for Mr. Morris, of Ireland, is to advertise his wants in the Times.

H. R.—*The drug prices given in the list, are those at which the wholesale houses buy drugs* before *profit.*

Mr. Tucker, Sligo, *will undoubtedly be able to register as a General Practitioner.*

Agricola.—*The answers, unfortunately, must be in the negative. There are no "accessible means of ascertaining the truth of the pretensions of any who profess themselves qualified to practice in medicine." There is* no *record, in most cases, which may be referred to to satisfy any who are disposed to institute the inquiry, whether the degrees of any practitioner are* really *taken whence they profess to be so taken. The remaining question depends for a safe answer in the knowledge of our correspondent's friends or acquaintances.*

H.—*The discreditable party knows better, if he pleases. The present body of surgeons will not be robbed of their privilege to recover by law for medical or surgical attendance. The contrary of this is the fact.*

An Enquirer *mistakes our meaning in imagining that we ascribe the replies specifically to the agency of the electro-magnetic telegraph. We meant to imply some* "such" telegraphic *communication, which may be all the less complex and difficult, as the*

ideas are more limited, and the distance of the communication it less. With electricity, as a telegraphic agency, a thousand things could be done more than the "Lady" does, in a better style, and with no such proximity; and considering the infinite varieties of "telegraphing," and how much may be done by even a change of position of the body, or a member of it, we must persist in our uncomplimentary opinion that the jugglery is "easy;" albeit we are sorry to be in dissidence with so clever a correspondent as Enquirer.

L. A. H.—*By the new Bill, M.R.C.S. may register as a "Surgeon," not as a Fellow. 2. L. A. H. after the Bill could legally retain his poor-law appointment. Now he cannot. 3. The M.R.C.S. will have the same privilege. 4. If L.A.H. register, as he says, as a General Practitioner, and become a "Fellow" of the new College, he will style himself "General Practitioner." 5. The M.R.C.S. will be in a similar position, but may style himself "Surgeon." 6. By the new Bill, the L.A.H. and the M.R.C.S. will occupy similar positions the one registering as General Practitioner and Apothecary, the other as General Practitioner and Surgeon. 7. The Bill will prevent all use of titles not possessed, and allow the use of all titles really possessed.*

A Lincoln Subscriber.—1. *After the new Bill pass, no druggist will be allowed, as now to call himself "Surgeon," or to prescribe or visit. 2. The M.R.C.S. will be allowed to recover, like an Apothecary, if he become a Fellow of the new College. 3. The Council of Health will most probably name the officership to a benefit club a "public office," in which case no one but a registered practitioner can fill it. He may be a General Practitioner, Apothecary, Surgeon, or Physician, at the free choice of the society.*

A Constant Reader, Liverpool.—*The possessor of a diploma from the "Faculty" at Glasgow, will be entitled to register as a General Practitioner. There is some little doubt as to the legality of the diploma beyond a certain district.*

Communications from Dr. Rigby, Dr. Costello, Dr. Clay, Dr. Wright, and Dr. Lewins, will appear in our next.

"Medicus," Limerick, *asks as many questions as a page of close print would not suffice to answer. For the* curricula *of the Universities of Heidelberg and Giessen, we must refer to "The Medical Guide and Almanack" for* 1845. *Both, however, have been published in the* Medical Times. *The medical points raised will be found considered in the last edition of Cooper. Contributions we do not accept except from known writers. The work of Prout is the best.*

The continuation of Dr. Wright's contribution on the Pathology of the Saliva, next week.

A Constant Reader *will find our opinions on the same point in other answers.*

D. F. R. *should have authenticated his letter on the Westminster Operation.*

Lucius *refers us to a letter that has appeared from him in the "Morning Herald." Its aim is to shew, in answer to a late parliamentary debate, that the inquiry instituted some years since into the condition of the Scotch universities, arose from complaints that two of them were selling degrees to anybody for money, and a third was reducing extremely low the standard of education. Lucius pays a handsome compliment to the University of Edinburgh as an honourable exception.*

A Subscriber, M.D., &c.—*The Supplementary Register allows, we think, the double privilege. The new Bill respects all existing titles and legal privileges. It allows every legal practitioner to be a Fellow of the new College; it allows him* also *to register the whole of his collegiate qualifications, and does not except him from any of the privileges of the new College.*

N. S. N. *should consult a brother practitioner.*

C.—*The Dublin "Sheet" has been received, and part of its contents will be noticed.*

If Dr. Tucker, East Lavington, favour us with his views compendiously given, on the question of the extra-licentiates, we will carefully consider them. The topic is likely to increase in importance.

Alpha (M.D., M.R.C.S., L.S.A.)—*We have in type a letter and memorial on double qualification from our correspondent. The Bill, however, giving in its supplementary register the privilege asked, the communication is now out of date.*

"A Subscriber."—*Every Irish and Scotch surgeon now resident in England is allowed, by the new Bill, to become a "Fellow of the Royal College of General Practitioners" without further fee or examination.*

M. D.—*The whole paltry attempt to raise a new movement against the Association, is founded and supported on a series of false pretences, which no gentleman could participate in. A few days will prove this fact in a very striking manner.*

A HANDSOME PORTFOLIO *for holding the* "MEDICAL TIMES,"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price* 5s.—*An allowance is made to the trade.*

THE MEDICAL TIMES.

SATURDAY, MAY 31ST, 1845.

Accendit praeterea animos et stimulat, dolor, injuria, indignitas. ** Crudelissima ac superbissima gens sua omnia suique arbitrii facit: circumscribit, includitque nos terminis montium fluminumque quos ne excedamus: neque eos quos statuit terminos observat.—LIVY.

THE Council of the College of Surgeons see at last at their doors the peril against which we had always warned them as the sure result of their childish policy of exclusion and insult. The Bill, they say, will revolutionize their establishment, and put the General Practitioner in a corporate position of worse than formidable rivalry. They are therefore against the measure, and are now using all the exertions they can command to oppose it. It is but another folly. Their condemnation of the Bill will give it the stamp of general approval. The more they wince under the blow, and the more it threats to shape down their fortunes to their capacities, the more rejoiced will be the Profession. The members, injured, scorned, degraded, and libelled in the Council's day of strength, laugh at their wants in the present hour of their weakness. When,—out of a foolish desire to belie the version we gave of their temporary return to good sense, —they abandoned that course of moderate concessions on which they were just entering, they sealed—as we then told them—the fate of their College as a great National Institution. The position of sullen immobility — public men shrinking in fear from the responsibilities of their office, and in the tremors and dubitations of incompetency inertly watching the gradual augmentation of their peril—this position was the sure and shortest means of necessitating those innovations, which, with the College of Physicians, they now so energetically deprecate.

If these gentlemen have so much to deplore, it is fair to suppose, that when the Bill is properly considered, there must be found about it not a little that is favourable to those members whom they have dealt with so hardly. And to give the measure this just consideration, we must not forget that it opens to us a twofold operation, and that a great point in discovering what we have to struggle about, is not to confound the Bill's action on the *present* with its action on the *future* body of medical men.

To our brethren in actual *general* practice there can be no doubt that the Bill is a boon. They have no privilege, or power, or position, which is in one iota impaired, and new privileges, and new powers are gratuitously and unconditionally added. *In their mutual relations with one another*, a better footing is established. General Practitioners, if "men of good will," are knit together in one body. With qualifications—many or few—high or low—from this source or from that—they are, if actually and legally General Practitioners, *i. e.*, members of the brotherhood, they are incorporated in one college, in whose government they will share—in whose interests they will participate —in whose success they will all mutually triumph. On the one side, while the General Practitioners with higher diplomas receive higher recognition and respect—on the other, those more humbly placed acquire elevation as honorable to themselves, as it is free from disparagement to others; and thus, in the new link of one common interest—in the new partnership of one participated boon—nine-tenths of the old causes for discord, ill-feeling, alienation, and comfortless hate will disappear as if by magic.

In reference to PRACTICE the benefit is not less equivocal. Under the present law, there is all but insuperable difficulty in recovering, by law, resisted medical bills. No engagements are broken by the dishonest with more ease, or unfortunately greater success. By the Bill however, our title to sue is made plain and explicit, and the ordinary registration list will be the triumphant proof of a true legal qualification. Our practice thus better protected from the *dishonesty* of patients, will also be better secured from their *folly*. They cannot again trust their lives, under a *delusion*, in the hands of the empiric. For the future, they must commit the blunder with their eyes open. The quack dare no longer pass himself off as a medical man. The powers, again, of the Apothecaries' Act will not be left longer to slumber. Made now a protection, not to the Apothecary only, but to every General Practitioner—aye, a protection to the very Surgeon it once punished—it will depend for its execution, not on the interest or caprice of an irresponsible corporation, but on the behests of the General Practitioners themselves. *They* will elect the Council that wield the powers of repressing wrong, and if the new broom do not sweep the professional pathways clean, the fault will be in those who mischoose their servants. The field of *medical* practice thus confined to *medical* men—will the pure Surgeon or the Physician obtain by the New Bill, a greater proportional share? We cannot think it. The Physicians and pure Surgeons get nothing by the Bill which they had not before; and no single circumstance will be presented to the public by the law of the country supporting their claim to any kind of superiority, but "their formation of a preliminary board of examination" (*should* that remain), and their asking from candidates for their diplomas a somewhat more advanced age. These, practically, are such trifling circumstances, that Physicians and pure Surgeons will offer the public no inducement to support their isolated gentility with the higher fees they claim, except a superiority of scientific reputation. If, in fair competition, they vindicate and maintain that higher reputation, we are not the persons to envy them the higher reward. The New College, however, may so closely contest the distinction, that the probability is not small, that the bodies of Physicians and pure Surgeons will daily lessen to suit the lessening want of the public, and that ultimately they will be composed, almost wholly, of those who by long and extensive general practice have established so wide and enduring a reputation, as to be able to afford the luxury of a "consultantship."

All these are important points in reference to the all-important point—*practice*; but its greatest point of all connects itself with the facility with which new competing members will be ushered into our body. The present system has given us a great superabundance of Practitioners, and some nineteen or twenty speculating mercantile establishments, called Universities and Colleges, have a direct pecuniary interest—an interest, in some cases of solvency or bankruptcy, of life or death—in adding daily and hourly to the surplus. In their fervid competition they have so lowered terms, that we would take odds that between the English

Irish, and Scotch Houses, we could manufacture a regiment of common soldiers into as many doctors, at six months' notice, and almost at any price.

The New Bill will dam up this inundation. For the future, no new candidate will secure membership without undergoing the preliminary examination that becomes a gentleman, without passing at least five years in medical studies, and without standing that test of a thorough and carefully supervised scientific education, which befits a man aspiring to the perilous responsibility of a doctor. We shall thus be better educated, better qualified, fewer, more successful, more respectable. Here, after all, is the corner-stone of improvement for the Profession. Here is the lever power by which the dignity of Medical Practitioners will be raised. Exactly with the same force and vehemence as we condemned the last form of the Bill for its *two*-year incoptorships, do we approve and applaud it as now amended with its *five* years' medical studies.

Having thus considered the New Bill in its reference to our personal relations mutually, and its certain effects on the actual practice of our Profession, we ask to be indulged with one word on the improvement it introduces in our government. In the Council of Health, we have, at least, a guarantee that the pranks and fantastic tricks too often played by some of the corporations, shall no longer be exhibited in perfect security. The Council can be forced by even the General Practitioners to *consider* grievances, and if they will not do their duty, the Home Secretary, their president, has those in the House who will not hesitate to ask for a reason. The great grievance that the qualifications, the studies, the funds of General Practitioners are at the utterly irresponsible control of a class of "pure" surgeons whose main aim is to degrade and injure those that support them—this enormous grievance will cease. The General Practitioners will rule themselves, spend their own money, control their own education, make their own chiefs, and this in a royal college, whose greatness will depend on themselves. In such a new position of power, with such a new centre of action, it is difficult to comprehend to what extent the government of the two other colleges may be influenced and improved.

The future race of General Practitioners will not stand to the Bill in the same relation as we shall. *We* have all that the old laws have allowed us, with all that the new law will give. *They* will have nothing but what the new law gives to the whole class of General Practitioners. They will stand or fall simply on their merit as General Practitioners. With the preliminary education of gentlemen, and the subsequent education of accomplished medical men, they will have nothing to shew but their diploma as Fellows of the New College, acquired by two or three years *more* surgical studies than sufficed to make a "Surgeon" under the old *regime*. Undoubtedly thus a high class of practitioners, the additional eclat they will derive from their College, will depend mainly on the wisdom and spirit of those in whose hands the precious deposit of the New Charter shall be confided. If the first Council is to be composed, as we understand, of twenty town and twenty country Practitioners of eminence, each characterised by the same industry and zeal as the gentlemen, who, up to this moment, have conducted the National Association to so high a position of power and utility, we cannot doubt, with such an agency, that from the elasticity of the professional mind of this country, a powerful re-action in the promotion of science will arise, and that, in a very few years, among the Colleges of our country, few will be so far advanced in the race of distinction as the Royal College of General Practitioners in Medicine, Surgery, and Midwifery.

Non equidem studeo bullatis ut mihi nugis
Pagina turgescat, dare pondus idonea fumo.—Persius.
Spectatum admissi, risum teneatis? Horace.
